**26.71** The English and Welsh RTDs met on 24 April 1974.<sup>107</sup> Dr Albert Bell attended on behalf of the SHHD and Dr Brodie Lewis, Director of the Aberdeen RTC, attended on behalf of the SNBTA. There was discussion of an article that had appeared in *The Sunday Times* in connection with a decision by the North London Blood Transfusion Service, Edgware, to suspend use of blood collected from donors from tropical areas who were considered to be a 'high risk' group as a result of having a higher incidence of Hepatitis B antigen.<sup>108</sup> It was agreed that an ad hoc group should be formed to consider 'what groups of donors can be identified, the use of whose blood should be given special consideration and whether any groups can be identified whose blood should be rejected'.<sup>109</sup>

**26.72** In July 1974 the NBTS in England and Wales compiled data for two periods: the year 1973 and January to March 1974.<sup>110</sup> The data for the whole year showed values for the incidence of HBsAg (Hepatitis B surface antigen) and anti-HBs (Hepatitis B antibody) in new general public and factory donors of 1:1107 and 1:772 respectively. In prisons, borstals etc, the relative values were 1:214 and 1:338 respectively. The incidence of infection in penal institutions in 1973 was relatively high.

### 1975–1979

**26.73** On 6 January 1975, Professor J Garrott Allen, Stanford University School of Medicine, wrote to Dr Maycock, Director, Elstree.<sup>111</sup> It appears from his letter that by the beginning of 1975 some practitioners in the United States of America were campaigning for a volunteer blood donation programme that would exclude high-risk donors in certain groups from giving blood. Professor Garrott Allen pointed out the increased risk of hepatitis from Factors VIII and IX produced by US commercial companies using blood taken from high risk donors. He also stated:

The other imponderable which has troubled most of us is the ineffectiveness in screening for the HB antigen ... Whatever this agent(s) may be, it still seems to be more frequently encountered in the lower socio-economic groups of paid and prison donors. It is minimal among volunteer donors. It seems that the most certain method we have for reducing the number of carrier donors at the present time is still to determine whether or not the donor has been paid in money or reduction of his prison sentence.<sup>112</sup>

<sup>104</sup> Minutes of Meeting [SNB.004.2488]

<sup>105</sup> Dr Maycock was Director of the Elstree, London, RTC and Chairman of the Advisory Group on Testing for the Presence of Hepatitis B Surface Antigen ('The Maycock Group') established by the then three territorial Health Departments in 1970.

<sup>106</sup> Minutes of Meeting [SNB.004.2488] at 2493, item 42(1)

<sup>108</sup> Ibid [SGH.001.7096] at 7099–00. See also a memorandum dated 18 April 1974 from TE Cleghorn, Director of the North London BTC, Edgware, which explains the background to this issue [SNB.001.2494]. It is also noteworthy that Dr Cleghorn stated in the memorandum that 'the detection efficiency of IEOP is probably not much better than 50%'.

<sup>109</sup> Minutes of Meeting [SGH.001.7096] at 7100

<sup>110</sup> 'Frequency of HBAG and Anti-HBAG Exported by RTCs IN New General Public and Factory Donors and in Donors in Armed Forces and in Prison Borstals and Similar Institutions' [SGH.001.7095]. The numbers for prisoners in that quarter of 1974 were small.

<sup>111</sup> Letter [SGH.004.6061] BPL Elstree was the manufacturer of NHS concentrates in England

<sup>112</sup> Ibid [SGH.004.6061]

**26.74** Professor Garrott Allen had previously published a book in which he had reported the results of his studies into post-transfusion hepatitis in the USA and had stated:

The risk of serum hepatitis from transfusions derived from prison and Skid Row populations is at least 10 times that from the use of volunteer donors.

....

The most practical methods of reducing the hazard of serum hepatitis from blood are ... especially by excluding, if possible, all prison and Skid Row or commercial donors.<sup>113</sup>

**26.75** In his evidence to the Inquiry Professor Cash stated that he was not, at the time, aware of Professor Garrott Allen's letter to Dr Maycock but was aware of 'the whole issue of the dangers of paid donors'.<sup>114</sup> He commented that paid donation was not a phenomenon in the United Kingdom. Similarly, Dr McClelland was not aware of the letter but was aware of Professor Garrott Allen's book highlighting the risks associated with paid donors.<sup>115</sup>

**26.76** For his part, Professor Leikola was unaware of Professor Garrott Allen before being asked to assist the Inquiry as an expert witness. On being shown Professor Garrott Allen's letter to Dr Maycock he commented:

I think that it's very much in line with what we did in Finland. However, we were thinking at least at that time that these problems of prison conditions and drug addiction were quite different in America as compared to northern Europe and therefore we were not quite as anxious of these numbers as they were over there. However, I think that this statement here is very much in line with what was thought in our country.<sup>116</sup>

**26.77** In February 1975 the Advisory Group on Testing for the Presence of Hepatitis B Surface Antigen ('The Maycock Group'), established in 1970, produced a draft version of their second report.<sup>117</sup> In May 1974 a sub-group of the Advisory Group had considered the problem of certain parts of the population in whom the incidence of HBsAg was known to be high.<sup>118</sup> The report of the sub-group was included in an appendix to this version of the report of the main group.

**26.78** As regards blood collected in prisons, the appendix noted:

There is a relatively high risk of hepatitis being transmitted by the blood of prisoners. But there is probably an equally high risk in other groups of the population, e.g. drug addicts, who are not as easily identified in advance as prisoners. It is not necessary to discontinue the collection of blood at prisons and similar institutions provided all donations are subjected to one of the more sensitive tests referred to ... above [RPH or RIA].<sup>119</sup>

<sup>116</sup> Day 13, page 42

<sup>117</sup> Second Report of the Advisory Group on Testing for the Presence of Hepatitis B Surface Antigen and its Antibody [SGH.003.0259]. Dr John Wallace, Director of Glasgow and the West of Scotland RTC was a member of the group.

<sup>118</sup> Second Report [SGH.003.0259] at 0265

<sup>119</sup> Ibid [SGH.003.0259] at 0286

**26.79** The appendix was not included in the final version of the second report of the Advisory Group, published in September 1975.<sup>120</sup> Instead, the conclusion reached by the sub-group on the continued collection of blood from donors in prisons was reflected in a letter dated 1 May 1975 from Dr Henry Yellowlees, Chief Medical Officer for England, to all Regional Medical Officers in England.<sup>121</sup> Dr Yellowlees noted that the DHSS had recently received advice from a group of experts<sup>122</sup> on the use of blood donations from certain categories of donors. The letter essentially repeated the wording of the appendix of the draft second report of the main group and, in relation to prisoners, stated:

There is a relatively high risk of hepatitis B being transmitted by the blood of prisoners. But there is probably an equally high risk in other groups of the population, eg drug addicts, who are not as easily identified in advance as prisoners, if they can be identified at all. The advice we have received is that it is not necessary to discontinue the collection of blood at prisons and similar institutions provided all donations are subjected to one of the more sensitive tests referred to above [that is, reversed passive haemagglutination (RPH) and radio-immunoassay (RIA)].<sup>123</sup>

**26.80** The issue of the use of prisoners as blood donors was determined for the time being for England and Wales by Dr Yellowlees' letter. That letter further noted that the *Memorandum on the Selection, Medical Examination and Care of Blood Donors*, issued for the guidance of RTDs, would be revised to take account of the advice received and that a copy of the letter was enclosed for each RTD.

**26.81** A copy of Dr Yellowlees' letter of 1 May 1975 was also sent to the SHHD. Dr Graham Scott, Deputy Chief Medical Officer, noted in a memorandum of 8 May 1975<sup>124</sup> that the Maycock Group had set up a small working group to consider 'geographical and racial factors' and produced recommendations in the form of an appendix which appeared in an early draft of the report, but that '[i]t was our view as soon as we saw it and indeed finally the view of the whole Advisory Group that the inclusion of such an Appendix could be inflammatory and the Appendix was therefore dropped'.<sup>125</sup> Dr Scott further noted that all he intended to do with Dr Yellowlees' letter was to ask Dr Archibald McIntyre, Medical Officer, SHHD, to discuss the recommendations with the National Medical Director of the SNBTS and to establish the practice in Scotland at that time and when the more sensitive methods of antigen screening had been instituted. He also indicated that if the practice recommended was not what the Scottish centres were doing, or intended to do, then all that would require to be done would be for the department to send a letter to the National Medical Director drawing his attention to the recommendations and asking him to take the matter up with the Regional Directors.

**26.82** On 16 May 1975 Dr McIntyre sent a copy of Dr Yellowlees' letter to Major-General Hugh Jeffrey, National Medical Director, SNBTS.<sup>126</sup> The emphasis in Dr McIntyre's letter was on blood from donors from endemic malarial areas and related to the risk of transmission of malaria. There was no discussion in Dr McIntyre's letter of donations from prisoners.

<sup>120</sup> Final version of Second Report [SGH.003.0079]. The recommendations may have exceeded the working party's terms of reference: Dr Wallace's letter to Dr McIntyre dated 5 March 1975 [SGH.003.0243]

<sup>125</sup> Ibid [SGH.003.0185]

<sup>126</sup> Covering letter [SNB.002.5017]

**26.83** Dr Yellowlees' letter of 1 May 1975 was circulated to the SNBTS Directors and was considered at their meeting on 11 June 1975.<sup>127</sup> The discussion appears to have been restricted to the question of blood from donors from endemic malarial areas. The minutes do not record any discussion of donations collected from prisoners, including whether the practice should continue. Professor Cash had no recollection of the discussions which took place at that meeting but concluded that the SNBTS accepted the views of the CMO (England), which he suggested almost certainly enjoyed the support of the CMO (Scotland) and that of the Senior SNBTS Director, Dr John Wallace.

**26.84** Dr McClelland was not aware of Dr Yellowlees' letter at the time it was distributed. In giving oral evidence, he thought in retrospect that it was very strange and surprising advice from a CMO, a public health doctor. He did not know from the letter where the expert advice on transfusion came from but suspected it might have been from a committee chaired by Dr Maycock, a subgroup of that advisory group. He had never been privileged to see any of the deliberations of that subgroup. He repeated that it was 'a very surprising letter'.<sup>128</sup> He was asked to comment further on Dr Yellowlees' advice and said:

The change, obviously, here was all about suddenly having a test for Hepatitis B. I feel that the advice about prisons surprises me because it's wider than just hepatitis ... I would have expected an experienced public health expert to have been concerned about essentially the whole gamut of infection risks among prison donors and also about possibilities of ... prisoners being poorly nourished perhaps being rendered iron-deficient. There would be quite a lot of reasons why [in] what is essentially a pretty underprivileged community, one should think very carefully about asking them to donate blood, both from the safety of the patient and possibly also for the safety of the donor. I do find it surprising, despite that statement.

Q. So in 1975, if one was considering the practice of collecting blood from prisoners, should there have been any consideration of whether there was a higher risk of prisoners transmitting infection?

A. I think that's what I'm saying .... The focus here was on Hepatitis B, and I think there must have been a period after the discovery of the Australia antigen by Blumberg et al, which moved very rapidly on to having some really rather insensitive tests, when ... there was a sense that we have cracked the problem of hepatitis, and in the background these guys, particularly in the States, were very rapidly realising that they probably hadn't cracked the problem of hepatitis. Then, when the Hepatitis A tests became available and the importance of examining liver enzymes perhaps became more widely realised ... it very quickly became evident to people who were looking at all the facts that there was something else going on.

Q So again trying not to look back with the benefit of hindsight, do you think that any consideration between, let's say, 1975 and to the end of the 1970s, the second half of the 1970s, of whether it was appropriate to continue to collect blood from prisoners, or any such consideration to have included consideration of the question of non-A non-B hepatitis?

---

<sup>127</sup> Minutes of Meeting [SNB.002.4995] at 4999, para 9

<sup>128</sup> Day 9, page 74–75

A. I think to put it in those specific terms is probably asking for an incredibly quick knowledge transfer, to be quite honest. I mean, we are talking about these earliest inklings that there was another entity which are referred to here. It is perhaps a little unreasonable to expect that to move instantly into a completely different context and be considered carefully and reflected on and applied. Life's not like that.

Q. So not even between 1975 and, say, 1979?

A. That's a matter of opinion. This is conjecture, not evidence.<sup>129</sup>

**26.85** Dr McClelland did not know whether the view expressed in Dr Yellowlees' letter had ever been retracted. He accepted that it represented the government's advice and thinking at the time.<sup>130</sup> In some respects, however, his views were rather equivocal. He said he would have expected someone with an overview of some of the basic issues in public health to have paused and thought, 'Hang on, prisons can't be a very good idea'. It had been known for a long time, and he considered that common sense would tell one, that prison was a place where living hygiene standards were not very good, where there would be people who had difficult lifestyles and so on. All gathered together, it just did not make sense to him.<sup>131</sup>

**26.86** The second report of the Maycock Advisory Group was published in September 1975.<sup>132</sup> As noted above, the appendix that had appeared in an earlier version of the report setting out the views of the sub-group, on the collection of blood from donors from endemic malarial areas and from prisons, did not appear in the final report. The second report noted that blood and blood products could also transmit other forms of hepatitis which did not appear to be associated with the presence of HBsAg.<sup>133</sup> In a chapter on safety in laboratories the report noted that specimens from various categories of patient should be labelled 'high risk' at the time of collection, including specimens from drug addicts.<sup>134</sup> As noted above at paragraph 29.79, as a result of the procedures adopted the Advisory Group's views on prison collections were not published generally as part of its second report but were, rather, incorporated with advice to medical professionals issued by the Chief Medical Officer for England.

**26.87** In 1977 Dr Edward Follett and Dr Ajay Chaudhuri reported on the link between drug abuse and Hepatitis B Infection.<sup>135</sup> The authors compared the risk factors in cases of acute HBsAg in Greater Glasgow with the risk factors in such cases across the whole of Scotland and concluded:

It is apparent from these observations that drug abuse is giving rise to a very significant number of the total cases of acute hepatitis B in Scotland. The noted percentage for 1976 (27.2) is very likely an under-estimate as several patients may not be asked about or admit to drug abuse or association with drug abusers. It is also evident that this is not another problem peculiar only to the

west of Scotland. It occurs throughout Scotland and what is seen in Glasgow reflects but does not magnify what occurs in the whole of Scotland.<sup>136</sup>

**26.88** In his book published in 1977, *Blood Transfusion for Clinicians*, Dr Wallace (Dr Mitchell's predecessor at Glasgow) commented, in a chapter on the collection and administration of blood:

Inmates of prisons and other institutions should be treated in the same way as other volunteers, provided the donation is proved to be HBsAg negative.

In respect of the transmission of viral hepatitis particular attention should be paid to volunteers who [are] suspected of being drug addicts or who have a tattoo. It is probably wise not to accept a volunteer who has been a drug addict.<sup>137</sup>

**26.89** In a chapter on the hazards of transfusion therapy Dr Wallace stated:

This is the appropriate time to consider certain controversial features of donor selection in respect of the transmission of hepatitis by transfusion. It has been established that within any potential donor population, certain groups have a higher than average incidence of HBs antigenaemia. In particular, HBs antigenaemia is more prevalent in male prisoners, and in volunteers from tropical areas. Some transfusion services have declined to accept volunteers in prisons and among immigrant populations. This ultracautious approach may be doubly undesirable. Few transfusion services have so much donor blood available that offers of substantial help can be refused in blanket fashion. Indeed visits to prisons to collect blood can often be arranged when the general intake of blood is low because of the holiday season. The incidence of HBs antigenaemia among male prisoners in Scotland is less than 1 per cent using the most sensitive techniques of testing, thus generous offers of useable donations would be lost by placing a total embargo on prison donors. Furthermore it is socially and psychologically undesirable to exclude prisoners and volunteers from tropical areas from the donor population. Acceptance of prisoners as donors helps to rehabilitate, and some of these volunteers become regular donors after their release.<sup>138</sup>

**26.90** Dr McClelland's general comments on Dr Wallace's book are noted in Chapter 14, *Knowledge of Viral Hepatitis 1*, paragraph 14.26. In his view the underlying assumption that, with the benefit of HBsAg screening and a low incidence of Hepatitis B infection, 'somehow non-A, non-B hepatitis just wasn't a problem in the UK', was inconsistent with the knowledge that only 25% of cases of post-transfusion hepatitis could be explained by Hepatitis B and that other causes, including Epstein-Barr virus, were not significant. He had similar difficulty with the conclusions of Dr Maycock's study which appeared to conclude that non-A, non-B Hepatitis was not a major transfusion problem.

<sup>138</sup> Ibid [LIT.001.3058] at 3106

**1980–1984**

**26.91** Research interest continued in to the 1980s. A workshop on hepatitis was held in Edinburgh on 8 January 1981 where Dr Brian Dow of the Department of Infectious Diseases, Glasgow University, gave a presentation on preliminary work he had carried out in Glasgow and the west of Scotland. A paper was later published.<sup>139</sup> The donor population studied included 352 prison donors, among whom Hepatitis B infection was known to be much more prominent than among the ordinary blood donor population and among whom it was expected that markers of NANB Hepatitis might also be more common, since NANB Hepatitis was a blood-borne virus assumed at the time to be similar to Hepatitis B.<sup>140</sup> SGPT/ALT<sup>141</sup> testing showed that of the 352 prisoners, eight had ALT levels exceeding the upper level of normal, at 35; six had levels greater than 42 and one had a level of 125. Of 164 other donors, only one exceeded 35 and one exceeded 42. Dr Dow would have expected more of the other donors to test positive. Even allowing for that, however, prison donors showed a higher level of elevated ALT compared to usual donor sessions.<sup>142</sup>

**26.92** In the discussion section the authors noted:

The index case of [NANB] hepatitis is usually in a haemophiliac, drug-abuser, or post-transfusion patient who may have developed jaundice as a result of a transfusion or a toxic reaction, and not from infection by an unknown agent.<sup>143</sup>

**26.93** In his evidence to the Inquiry, Dr Dow was asked what was meant by the words in the article, 'among whom it was expected that markers of [NANBH] might also be more common'. He replied:

It was basically because non-A, non-B Hepatitis was thought to be a blood-borne virus similar to Hepatitis B. We were just assuming that it was very similar to Hepatitis B.<sup>144</sup>

**26.94** Dr John Gillon's evidence (paragraphs 26.103–26.104 below) would indicate that the assumption was not necessarily well founded but the results, showing a higher incidence of elevated ALT, provided independent evidence of a higher prevalence of NANB Hepatitis (subject to all of the reservations about ALT testing explored later).

**26.95** At the same workshop Archibald Barr and others also presented data showing that the west of Scotland prison sessions had an increased incidence of both HBsAg and Hepatitis B antibodies compared to the general donor population.<sup>145</sup> Over 10 years more than a million donations had been tested for HBsAg. The incidence in institutionalised males was 1:145, compared with 1:693 in non-institutionalised males. In oral evidence, Dr Dow said:

That's about five times greater. It is also quite important to notice there as well that in the ten years, as far as donors tested for the first time, we only had

<sup>139</sup> Dow, Follett and Mitchell, 'Non-A, non-B Hepatitis markers in the west of Scotland', *Laboratory Sciences*, 1981; 38:359–363 [PEN.014.0074]. A final report was published in 1984.

<sup>140</sup> Dr Dow – Day 8, pages 131–132

<sup>141</sup> Alanine transaminase (ALT), sometimes referred to as serum glutamic-pyruvic transaminase (SGPT), is a protein synthesised in liver cells. Normally present in low levels in the blood, it becomes elevated when the liver is disordered by virus infection or other hepatic disorders.

<sup>142</sup> Day 8, pages 132–134

<sup>143</sup> Dow, Follett and Mitchell, 'Non-A, non-B Hepatitis markers in the west of Scotland', *Laboratory Sciences*, 1981; 38:359–363 [PEN.014.0074] at 0078

<sup>144</sup> Day 8, page 132. See also pages 149–150.

<sup>145</sup> Barr et al, 'Hepatitis B surface markers in blood donors in the west of Scotland', *Medical Laboratory Sciences*, 1981 [PEN.014.0068]

6234 institutionalised donors tested for the first time. And you would expect that sort of figure in roughly two years, when you think about it. So we had a lot of repeat donors from prisons. And they had obviously been screened and, you know, obviously if they had been screened they were negative.

....

What I'm trying to get across is when you go to prisons, they are not all new donors. When we go to prisons, some of them have actually given before. So what we are talking about in the 1 in 145 is that if you had, let's say 290 blood donors actually donated at a prison session, you aren't going to get two Hep B positives there, you are probably going to get maybe 0.5.<sup>146</sup>

**26.96** The authors of the west of Scotland paper further stated:

Despite the high incidence of HBsAg in male prisoners ... viral hepatitis is not a serious clinical problem in the institution surveyed, and the positive donors are not drug addicts. This high incidence is probably related to social habits and hygiene.<sup>147</sup>

**26.97** Dr Dow said of this study that he assumed intravenous drug users would have been excluded by the donation staff.<sup>148</sup> If that was correct, the total incidence of positivity would have been higher than found in those proceeding to donation.

**26.98** Dr Mitchell was asked in oral evidence if he knew the basis for the statement that 'the positive donors are not drug addicts' and replied:

Dr Crawford was one of my consultants at that time and he, of course, had a close interest in this work. And it's over a period of ten years ... And Bob actually made a point of interviewing some of these people at the Prison Service, and saying, "Have you had any cases of hepatitis among the inmates since they were screened and do you have any evidence of any of these men being addicts?"<sup>149</sup>

**26.99** Dr Mitchell suggested that the reference to 'social habits and hygiene' did not refer to injecting drug use but may have included habits such as tattooing. He also stated that in the early days of blood transfusion intravenous drug use wasn't much of a problem and was something that came in 'much later'.<sup>150</sup>

**26.100** In oral evidence Dr Dow explained that 'social habits and hygiene' may have been a reference to homosexuality and the sharing of razors and toothbrushes, etc.<sup>151</sup> He was asked, with the benefit of hindsight what he thought was the likely explanation for the higher prevalence of Hepatitis B in male prisoners. He replied, 'Probably drug abuse of some sort'. That link was not made at the time and Dr Dow could not give an explanation for that, other than to say, as far as he was concerned, he was unaware of the amount of intravenous drug use among prisoners until seeing a newspaper report to that effect in March 1984.<sup>152</sup> Professor Urbaniak pointed out that some prisoners are liable to tattoo themselves, or others, and are likely to do so in unhygienic circumstances. He opined that,

<sup>150</sup> Ibid page 156

<sup>151</sup> Day 8, pages 99 and 141

<sup>152</sup> Ibid pages 142–143 and 150–151

before the marked increase in intravenous drug use in the early 1980s discussed below, tattooing was a more likely explanation for the increased prevalence of Hepatitis B in the prison population than intravenous drug use.

**26.101** In his evidence to the Inquiry Professor Cash stated that his impression was that the problem of drug use in UK prisons in 1983 was not the problem it is now.<sup>153</sup> While Professor Cash had no recollection of having seen the paper at the time, his view now was that the assertion that the positive donors were not drug addicts and that the higher prevalence of Hepatitis B probably related to social habits and hygiene, was an error and that the most likely explanation for the higher prevalence was drug use and needle sharing.<sup>154</sup>

**26.102** Professor Leikola was of the view that if he had read the paper by Barr and colleagues in 1981 he would have considered the explanation for the higher prevalence of Hepatitis B in donors being due to 'social habits and hygiene', as 'possible, but not probable'. He explained:

[A]fter seeing Dr Helske's article in 1975, and after having discussed this problem briefly, when the people from the prison administration approached Dr Koistinen, I think that these explanations brought forward by Dr Helske – that was illegal use of intravenous drugs, needle sharing and then tattooing – were probably more plausible explanations than this one. And if I would have read this very carefully, I would have really questioned whether the explanation here is correct.<sup>155</sup>

**26.103** Dr Gillon, Consultant Physician at the Edinburgh and South East Scotland BTS from 1985, having heard other witnesses discuss the situation at this time, drew a distinction of some importance based on the relative infectivity of the diseases. He said that there is a gradation from Hepatitis B being highly infectious through HIV being pretty infectious to Hepatitis C, as it came to be known, being not very infectious. In the mid 1970s it was known that in any sort of residential setting Hepatitis B was likely to spread: unlike with Hepatitis C, close family members of people with acute Hepatitis B or high level carriers of Hepatitis B are at risk, just through everyday contacts and excluding sexual contacts as a factor. The assumption that the reference to 'social habits and hygiene' was code for homosexuality was not necessarily correct. He thought that in situations like a prison, a residential school, or any institutionalised situation like the armed forces, Hepatitis B could spread quite readily.<sup>156</sup>

**26.104** Dr Gillon's observations made a particularly helpful contribution to understanding the evidence about infection in the prison population as a whole. On the one hand, they gave added weight to the risk of Hepatitis B transmission inherent in the institutional setting, tending to explain a high prevalence of infection among prisoners and, together with the known ineffectiveness of HBsAg testing, tending to reinforce the case against using prison donations. On the other hand, his evidence warned against the suggestion that a high rate of Hepatitis B transmission in the institutional setting necessarily implied a high rate of NANB Hepatitis transmission among prisoners. That would have to be investigated independently and, indeed, research proceeded to do so.

**26.105** In 1982 the appropriateness of collecting blood from prisons in Scotland was questioned by the Medicines Inspectorate. The Inspectorate interpreted widely its remit for monitoring the implementation of processing and manufacturing standards for pharmaceutical products. While the licensing regime did not apply to state bodies such as the SNBTS because of the doctrine of Crown Immunity, the policy of the NHS in Scotland at the time was to aim to comply with good manufacturing practice, as if Crown Immunity did not apply.<sup>157</sup>

**26.106** The Medicines Inspectorate visited the Edinburgh and South East Scotland BTS on 10-11 March and 10-12 May 1982. A report was subsequently issued, to which the Edinburgh and South East of Scotland BTS responded, as already noted, on 12 January 1983.<sup>158</sup> The report queried whether prisons and borstals were appropriate places to recruit donors.

**26.107** On 25 March 1982 the Medicines Inspectorate inspected the Dundee BTS.<sup>159</sup> The Regional Director, Dr Ewa Brookes, raised the question of prison donations with the Inspectorate. In her previous employment in London she had met them and regarded them as helpful critics, believing that they were likely to be supportive of her concerns. She advised the Inspectors that she understood that prison collection was in line with government policy but expressed her concern about the practice, as she had previously done whilst working in London. Her concerns were reflected in the Inspector's report.<sup>160</sup>

**26.108** The Inspectors' report of their visit to the Dundee BTS stated:

Brief discussions were ... held on sources of donated blood. At the time of this visit the Inspectorate had not visited donor sessions with Mobile Teams. However, it would seem most unlikely that we could continue to endorse the continued collection of blood from places such as Prisons and Borstals.

This recommendation is based on the following:

- (a) Prison Medical Officers are often not involved in assessing the suitability of donors.
- (b) The increased risk of infection associated with prison populations and the increased risk of transmitting disease through such donations.
- (c) The unreliable answers to the pre-donation questionnaire that can occur in such environments as well as the motivation of some of the donors.<sup>161</sup>

---

<sup>157</sup> The advice of Scottish Law Officers from 1979 was that Crown privilege applied to the CSA (see footnote 169) and Health Boards in Scotland, altering advice previously given. In practice, licences granted prior to 1979 were allowed to become time expired: letter from DHSS to SHHD dated 14 February 1983 [SNB.008.7481]. See a paper by Professor Cash, written in 1984 in which the position (after 1979) was set out, 'Medicines Inspectorate/SNBTS activities: current unresolved problems', dated January 1984 [SGH.001.3012] at 3013.

<sup>158</sup> Report [SGF.001.0351]; Response [SNB.008.6721]

<sup>159</sup> Report [SGF.001.0086]

<sup>160</sup> See witness statement of Dr Brookes, [WIT.003.0057] at 0060-0061: 'I regarded MI as a helpful critic and expressed my concerns. These were later reflected in their general report...'. Dr Brookes' experience of collecting blood from prisons in London is noted above at paragraph 26.53.

<sup>161</sup> Report [SGF.001.0086]

**26.109** The Inspectors' reports of their visits to the Glasgow and West of Scotland BTS on 8–9 March 1982<sup>162</sup> and the Inverness and North Scotland BTS on 5 May 1982<sup>163</sup> made no mention of the practice of collecting blood in prisons, though clearly the practice continued in the West of Scotland at least.<sup>164</sup>

**26.110** By letter dated 4 June 1982, Mr David Haythornthwaite of the Medicines Inspectorate sent a copy of the draft reports of the visits to Professor Cash.<sup>165</sup> Mr Haythornthwaite made a number of observations 'which may be "disconnected" but nevertheless apply to many centres'. In respect of 'source material', the selection and management of blood donors, Mr Haythornthwaite stated:

I have not observed donor sessions under the worst conditions however, I wonder whether certain 'high risk' areas are necessary or desirable. Prisons and Detention Centres would seem to come under this category and I would be interested in your views on this.<sup>166</sup>

**26.111** Professor Cash wrote to Mr John Watt, Scientific Director, PFC, on 5 July 1982 in respect of the Medicines Inspectorate's inspections.<sup>167</sup> Professor Cash noted that there were one or two items arising that deserved 'our collective (national) attention'. He further noted that 'We need to consider, formally, in the not too distant future, the question of Sessions in Prisons etc. I would very much welcome your comments as to whether we should abandon this practice'.

**26.112** In November 1982 Professor Cash prepared a General Response<sup>168</sup> in the name of the Common Services Agency (CSA)<sup>169</sup> to the inspection of SNBTS RTCs by the Medicines Inspectors. It was noted that a more detailed response would follow as soon as possible. The General Response referred to various steps that were under way including building works, the purchase of new equipment, staffing, improved record keeping and a quality assurance programme. There was no mention of the practice of collecting blood in prisons.

**26.113** The Edinburgh and South East Scotland BTS also prepared a response to the Medicines Inspectors' report, dated 12 January 1983.<sup>170</sup> It commented, in respect of the practice of collecting blood in institutions: 'Prisons and Borstals. We do not visit these regularly. No such sessions have been held for two years. These donors will only be used in an emergency'.<sup>171</sup> The response noted that the new comprehensive guide to donor selection, which had been prepared and sent to the Medicines Inspectorate, was in routine use by donor selection staff.<sup>172</sup> It did not distinguish the treatment of prison donors from donors in the general public.

<sup>162</sup> Report [SGF.001.0362]

<sup>163</sup> Report [SNB.008.8095]

<sup>164</sup> Although that may not be entirely surprising given that the Glasgow report stated: 'This visit was restricted to the manufacturing activities conducted at the Centre along with the Quality Control activities. No donor services were visited ...'. [SGF.001.0362] para 4, and the Inverness report stated: 'Insufficient time was available for an examination of all activities'. [SNB.008.8095] para 2.

<sup>165</sup> Letter enclosing draft reports [SNB.008.7582]

<sup>166</sup> Ibid [SNB.008.7582] at 7583

<sup>167</sup> Letter [SNB.005.6703]

<sup>168</sup> General Response [SGH.003.5165]. The General Response appears to have been approved by the CSA's BTS Sub-Committee before being forwarded to the Medicines Division on 2 June 1983 [SGH.001.3012] at 3013, para (a).

<sup>169</sup> Section 19 of the National Health Service (Scotland) Act 1972 provided for the constitution of the Common Services Agency for the Scottish Health Service (the CSA) with effect from 1 April 1974. Amongst its several responsibilities was the operational management of the blood services. See Chapter 17, *Blood and Blood Products Management*, paragraphs 17.23–17.27.

<sup>170</sup> Response [SGH.003.5059]

<sup>171</sup> Ibid [SGH.003.5059] at 5063

<sup>172</sup> Ibid [SGH.003.5059] at 5063. (As noted in paragraph 26.42 of this chapter, the last prison donor session had taken place on 22 December 1981.)

**26.114** Although collection from prisons had been raised by the Medicines Inspectorate in their draft reports sent to Professor Cash in June 1982, there is no minuted discussion of the matter at the meetings of the SNBTS Directors between June 1982 and March 1983.<sup>173</sup> Nor does the topic appear to have been discussed at the meetings of the Ad-Hoc Medicines Inspectorate Steering Group of the CSA.<sup>174</sup>

**26.115** Dr McClelland did not recall the topic of the collection from prisons having been discussed at any Directors' meeting prior to March 1983.<sup>175</sup> Similarly, Professor Cash did not recall having ever given the collection of blood from prisons any consideration prior to it being raised by the Medicines Inspectors in 1982. As Professor Cash put it in his evidence to the Inquiry: 'There were some big, big other issues and I suspect this was a casualty .... A major issue developed within the Scottish Office that major investment, capital investment, was going to be required [at PFC] to keep us on track with self-sufficiency'.<sup>176</sup> Professor Cash explained that during this time the SNBTS was 'heavily committed' to addressing the problems of plasma and haemophilia, in particular, 'the problem of national self-sufficiency in plasma products', which was 'a monumental task'.<sup>177</sup>

**26.116** The issue of prison collections became live in March 1983. The minutes of the Directors' meeting on 29 March<sup>178</sup> include comments on 'Blood Collection in Prisons and Borstals':

Dr Cash reported that the Medicines Inspector had commented adversely on the practice of collecting blood in prisons and borstal institutions, and he invited Directors to comment on the practices in each region and to give their views on the Medicines Inspector's criticism.

It was reported by all Directors present that sessions were held in penal institutions in all regions, although Dr Brookes and Dr Urbaniak intended to review the situation in their regions.

It was not possible for the Directors to agree on future policy, but it was agreed that Dr Brookes, as the Scottish representative, should ask the Working Party on the Selection and Care of Blood Donors to consider this issue. In the meantime, Dr Cash agreed to inform the Medicines Inspectorate of these SNBTS discussions and conclusions.<sup>179</sup>

**26.117** In oral evidence Professor Cash was asked if he had any recollection of the meeting on 29 March 1983 and replied:

My main recollections were that I was not the boss, that all consultants are equal, that I was merely there to co-ordinate and chair; that individual regional directors had the authority to stick to their view and so on and so forth. That was one of the main things.

<sup>173</sup> That is, at the Directors' meetings on 16 March 1982 [SGH.001.0119], 15 June 1982 [SGH.001.0101], 14 September 1982 [SGH.001.0055] and 14 December 1982 [SGH.001.0027]

<sup>174</sup> The Steering Group was set up in response to a report issued by the Medicines Inspectorate in relation to the PFC in November 1981. It met on 5 May 1982 [SNB.008.7309], 26 May 1982 [SNB.008.7393], 21 July 1982 [SNB.008.8235], 16 September 1982 [SGH.002.4287] and 11 November 1982 [SNB.008.8342] and produced a draft report in October 1982 [SNB.008.7278]

<sup>175</sup> Day 9, page 39

<sup>176</sup> Day 10, page 35

<sup>177</sup> Ibid page 75. Professor Cash further stated that he had no recollection of whether he was aware between 1974 and 1982 of the evidence suggesting that there was a higher prevalence of Hepatitis B among prisoners in the west of Scotland: Day 10, page 81

<sup>178</sup> Minutes of Meeting [SGF.001.0234]

<sup>179</sup> Ibid [SGF.001.0234] at 0238, para 7

I remember it being very heated because ... Dr Mitchell was very concerned that if this was precipitously implemented, he would run into problems of blood supply. These were regarded as local matters and we respected his position at that time.<sup>180</sup>

**26.118** This attitude to regional autonomy was common. In his written statement to the Inquiry Professor Cash explained that:

Without SNBTS Directors' consensus, there was no national management process for considering issues related to the location of blood collection sessions in the regions. Throughout the UK: this issue was strictly left to the RTDs and their teams and their priority was maintenance of supply. This management practice and the operational priorities enjoyed SHHD/DOH support.<sup>181</sup>

**26.119** Professor Cash was asked what his personal view was at the time about the appropriateness of continuing to collect donations in prisons and replied, 'I am as sure as I can be but not absolutely certain that my view was we should get out of that'. When asked why he was of that view he replied, '[o]n the grounds that the inspectors had raised, this is an issue, and for all of the reasons that they had stated'.<sup>182</sup>

**26.120** Professor Cash went on to say:

I don't think ... Dr Mitchell was totally opposed. I think the notion he felt of suddenly stopping when his donor programme had been planned for 12 months ahead and he foresaw major problems with shortages – we didn't second guess that, we accepted his point of view and it is very interesting that even by 1984 it had dropped from 2500 donors down to about 400.

So they were clearly, in 1983, as the others switched off finally, the West team were making strenuous efforts to detach at the same time ... Ruthven Mitchell found himself, he felt, in a very difficult position.<sup>183</sup>

**26.121** In her written statement to the Inquiry Dr Brookes stated, in relation to the meeting:

In discussion, I expressed my strong view that I thought the prison and young offenders sessions should be stopped, on the basis of my experience in London.

Although opinion was divided, it became evident that those Directors who wished to discontinue prison sessions, could do so.

....

In Dundee, immediately following the ... meeting of 29/3/83 I asked the Organising Secretary to phase out prison and young offenders sessions over the coming year.

The Centre's programme of donor sessions was generally confirmed for one year ahead, and outlined for the coming year.<sup>184</sup>

---

<sup>180</sup> Day 10, page 42

<sup>181</sup> Professor Cash's Witness Statement [WIT.003.0120] at 0124

<sup>182</sup> Day 10, page 46

<sup>183</sup> Ibid pages 94–95

<sup>184</sup> Dr Brookes' Witness Statement [WIT.003.0057] at 0061–62

**26.122** Professor Urbaniak succeeded to the post of Director for the North East Region, his predecessor, Dr Brodie Lewis, having retired on 3 March 1983. Professor Urbaniak attended the meeting on 29 March 1983 and formed the view that prison collection was undesirable and decided to review the practice in the NE region.

**26.123** By letter dated 12 April 1983,<sup>185</sup> Professor Cash advised Mr Haythornthwaite that the practice of donor sessions at prisons and borstals had been discussed at length by the SNBTS Directors at the meeting. He noted that '[o]pinion was strongly divided and it was not possible, at this time, to obtain a consensus view'; that, nevertheless, the Directors recognised that the problem would require further discussions; and, to that end, that Dr Brookes had agreed to raise the matter at the next meeting of the UK Working Party which was currently considering the whole question of donor selection and care.

**26.124** On 6 May 1983 Mr John Davies, Assistant Secretary, SHHD, sent a minute to the Private Secretary of Mr John MacKay, Under Secretary of State for Scotland, on the subject of AIDS.<sup>186</sup> The minute noted that there had been recent media comment about AIDS, that the DHSS had prepared briefing material for the Prime Minister and that there were a few Scottish points to be made, including:

Donation Policy

The Blood Transfusion Directors in Scotland are very aware of the problem and have it under constant consideration. They are currently considering:-

....

(d) Avoiding collection in high risk locations such as prisons or where there is known to be a high proportion of homosexuals or drug abusers in the population.<sup>187</sup>

**26.125** On 27 July 1983 Mr JB Brown, Medicines Division, DHSS, sent a minute to his DHSS colleagues on the use of blood from prisons.<sup>188</sup> In the minute he explained that, at a recent meeting of Medicines Division's Inspection Action Group, concern had been expressed about the collection and use of blood from borstal institutions and prisons. Blood Transfusion Centres in Scotland were making use of these sources, particularly prisons, and some, at least, of the English Blood Transfusion Centres were also understood to be doing so. He went on:

The Group considered this practice to be highly questionable because of the incidence of homosexuals and homosexual activity in prisons and the present unease about the incidence of AIDS among this group of people.

The Group asked to be advised of Departmental policy on the practice of collecting and using blood from borstals and prisons and I shall be grateful if you will let me have a note about this which I can pass on.

**26.126** A handwritten note on Mr Brown's minute records that Mr Winstanley, DHSS, was to consult with Dr Diana Walford and respond. An SHHD note dated 11 August 1983<sup>189</sup> recorded that Mr Winstanley had contacted the SHHD in respect of the Medicines

---

<sup>185</sup> Letter [SNB.002.6408]

<sup>186</sup> Minute [SGH.002.6764]

<sup>187</sup> Ibid [SGH.002.6764]

<sup>188</sup> Minute [SGH.001.0575]

<sup>189</sup> Note [SGH.001.0572]

Inspectorate's query relating to departmental policy on donor sessions in prisons and borstals 'given there is now AIDS'. Mr Winstanley told the SHHD: 'England and Wales have tended to shy-off in part because of Hepatitis' but he wondered what the Scottish practice was. The SHHD official referred to the discussion at the SNBTS Directors' meeting on 29 March 1983 in that regard. It was also noted that Mr Winstanley 'made the point that if policy was to be withdrawal, would probably need to consult Home Office in view of the importance placed on the social responsibility aspect of such sessions'.<sup>190</sup>

**26.127** By letter dated 23 August 1983,<sup>191</sup> Dr Brookes advised Professor Cash that the Working Party on the Selection of Donors/Notes for Transfusion had met for the first time on 30 June 1983. Dr Brookes had raised the matter of donor sessions at prisons and borstals but noted that '[i]n fact, no discussion was necessary since as far as England and Wales are concerned these sessions have already been stopped. It is now left to the Scottish regions to decide whether they will do the same'.

**26.128** In her written statement to the Inquiry Dr Brookes explained that:

[I]n 1983, the SNBTS National Director had asked me to raise the matter of prison sessions in the working party on Selection of Donors and when I did, I was advised by the chairman that there was nothing to discuss, it being his understanding that all English Transfusion Centres had stopped holding prison sessions. After the meeting I reported this to the Scottish National Director who asked me to ring round informally to check. I contacted 12 of the 14 Directors. In the minutes of the SNBTS Directors meeting of 8 December 1983 ... it is recorded that of the 12 Directors I had contacted, 11 were not holding prison donor sessions.<sup>192</sup>

**26.129** By minute dated 23 August 1983 Mr Winstanley, DHSS, replied to Mr Brown. He stated:

It is difficult to advise any particular Departmental policy on the collection of blood from borstals and prisons at the moment. It is for individual Regional Transfusion Directors to determine how and from where donations are sought in the light of the targets they need to achieve and the numbers of donors on their panels.

However, Transfusion Directors have been aware of the dangers of relying too heavily on prisons as a source of donations for some time i.e. prior to the advent of AIDS as a cause of concern, because of the risk of hepatitis in prisons, (also connected with the higher incidence of homosexuality) which can be spread through blood transfusion. Nevertheless, although most Regions, especially those with no shortage of donors, may not need to use prisons, there is at least one which has to view them as a major source of donations in order to meet targets.

AIDS has now of course called the wisdom of continuing to view prisons as a source of blood even further into question and the Directors are due to discuss it at their next meeting in September.<sup>193</sup> If the risks are now considered

<sup>190</sup> The note [SGH.001.0572] is as quoted: it does not indicate who would have the obligation to consult the Home Office.

<sup>191</sup> Letter [SNB.002.6554]

<sup>192</sup> Dr Brookes' Witness Statement [WIT.003.0057] at 0070

<sup>193</sup> In fact, the minutes of the meeting of the English and Welsh BTS Directors on 22 September 1983 contain no reference to the collection of blood from prisons having been discussed [SNB.001.3412]

too great to justify the continued collection from prisons, some measures will be needed to compensate for the loss of that source of donors, perhaps, for example, a system whereby Regions with no need to rely on prisons can take extra blood to be transferred to those Regions for whom the loss of prisons as a source of blood will cause difficulties ....

[I] gather that this problem has been debated by Transfusion Directors in Scotland, but no particular policy line emerged. We shall obviously need to liaise closely with Home Office also since they have in the past been very much in favour of blood donation by prisoners.<sup>194</sup>

**26.130** The SNBTS Directors met on 13 September 1983.<sup>195</sup> As regards the Working Party on the Selection of Donors/Notes for Transfusion, the minutes state:

On the matter of collection in prisons and borstals it was noted that the Medicines Inspector had expressed concern at this practice. Owing to different circumstances in the Transfusion Regions the Directors had been unable to reach a consensus. The Chairman of the Working Party thought that the practice was diminishing in all regions in England and Wales. Dr Brookes felt strongly that donations should not be collected from prisoners because of the uncertainty about replies to questions concerning health.

It was reported that the practice had been raised at the Medicine Inspectors' Action Group who had referred it to the DHSS Administrative Division who confirmed that some Transfusion Centres in England still collected from prisons and borstals and that cessation of this practice would place them in difficulty. The NBTS Directors were due to discuss the matter and the DHSS would wish to consult the Home Office who had been anxious previously to encourage donation in prisons.

It was acknowledged that prisons and prisoners differed greatly from one place to another and some Directors felt that a blanket decision to cease visiting prisons would be a mistake. Dr Mitchell in particular felt that it would be unfortunate if such a recommendation was to be included in the "Red Book".

Dr Brookes undertook to circularise the English/Welsh Transfusion Directors and report back to the meeting.<sup>196</sup>

**26.131** A note of the meeting by an SHHD observer recorded that:

The details in Mr Winstanley's minute of 23 August were reported to the meeting of RTDs on 13/9/83.

With the exception of the West of Scotland, RTDs were ceasing collection of blood at prison sessions.

The subject would be kept under review, particularly to hear of developments in England which might be influenced by Home Office views.<sup>197</sup>

<sup>194</sup> Minute [SGH.001.0574]

<sup>195</sup> Minutes of Meeting [SNF.001.0072]

<sup>196</sup> Ibid [SNF.001.0072] at 0077, para 8. The 'Red Book' was shorthand for the *Standards for the Collection and Processing of Blood and Blood Components and the Manufacture of Associated Sterile Fluids* (see paragraphs 26.21 above) compiled by the Medicines Division of the DHSS in conjunction with the UK Blood Transfusion Services, BPL, PFC and SHHD.

<sup>197</sup> Note [SGH.001.0571]. In a written statement provided to the Inquiry, Mr Wastle, an SHHD administrative officer who attended the meeting, stated: 'The Director of East of Scotland RTC was strongly against collecting donations from prisoners but some Directors considered that a total ban would be a mistake, with the Director of the Glasgow and West of Scotland RTC strongly opposed to a formal ban'. [PEN.010.0316] at 0319.

**26.132** The UK Blood Transfusion Services' Working Party on Transfusion Associated Hepatitis met on 27 September 1983.<sup>198</sup> Discussion was dominated by AIDS. In respect of donor sessions in prisons the minutes record:

Members asked if the chairman could provide details of which Centres took donations at Prisons. They realised that the definition of 'prison' ranged from 'closed' to 'open' prisons. The working party felt that prisons should be considered in the context of a 'high risk' population in terms of several of the transfusion-transmitted infections and as such should be avoided as a donor source.<sup>199</sup>

**26.133** The SNBTS Directors met on 8 December 1983.<sup>200</sup> As regards the Working Party on the Selection of Donors/Notes for Transfusion, the minutes state:

Reporting her consultation with the English/Welsh Transfusion Directors concerning collections in prisons and borstals Dr Brookes explained that only one of the 12 which she had consulted was attending prisons. It was noted that the only Scottish region to continue holding sessions in prisons was the West.<sup>201</sup>

**26.134** On 9 February 1984 a meeting on the infectious hazards of blood products was held at the National Institute for Biological Standards and Control (NIBSC), attended by Professor Cash and Dr McClelland.<sup>202</sup> There was discussion of AIDS and hepatitis. The minutes note:

The policies adopted in Scotland to minimise the risk of transmission of infection were explained. The three main strategies were 1) avoidance of high risk communities (such as prisons, known homosexual areas, etc.); 2) detection of clinical abnormalities by examination and careful questioning; 3) exclusion of the high risk donor, or his blood, always allowing an 'escape route' for the donor who is deemed unsuitable. Dr McClelland pointed out that it is essential to have well established and well documented procedures in order to carry out these fairly simple strategies.<sup>203</sup>

**26.135** In his evidence to the Inquiry Dr McClelland explained that AIDS 'was on top of everybody's mind at that period'<sup>204</sup> and led to a 'step change in the rigour of the donor selection procedures'.<sup>205</sup>

**26.136** In July 1984 Drs Dow and Follett produced a Final Report on their study into NANB Hepatitis in the west of Scotland.<sup>206</sup> The study period had been 1 September 1980 to 31 August 1983. The main aim of the study was to determine whether 'unrecognised viruses are circulating in the Scottish population resulting in cases of hepatitis which at present cannot be categorised' (ie NANB Hepatitis).<sup>207</sup> A total of 10,655 west of Scotland

<sup>206</sup> Report [SGH.002.8040]

<sup>207</sup> Ibid [SGH.002.8040] at 8043

blood donors had been tested for elevated ALT levels. It was noted that ‘screening sessions in prisons detected 10 times more donations with grossly elevated [ALT] levels compared to other sessions’.<sup>208</sup> The report commented that among the prisoners with high ALT levels, nine were found to be known drug users. In a section of the report on ‘Drug Abusers’ it was noted that ‘[t]he vast majority of users with elevated ALT levels admitted being heroin addicts and a considerable proportion were prisoners’.<sup>209</sup>

### 1985 onwards

**26.137** The Dow/Follett study formed the basis for Dr Dow’s PhD thesis, ‘Non-A, Non-B Hepatitis in West Scotland’, completed in October 1985.<sup>210</sup> In a discussion on ALT testing of blood donors the thesis commented:

Around one third of those with raised [ALT] levels were known to be drug abusers (ie they did not admit being drug abusers at the time of giving blood, but were found to be drug abusers when specimens were received from them at the HRL)<sup>211</sup>.... It must be assumed that this is a minimum number of drug abusers as many more are known to exist in prisons and many will not readily admit abuse. In a Scottish newspaper (Sunday Post, 1984)<sup>212</sup> it was reported that Scotland’s prisons are now the country’s largest drug treatment centres. In 1973 only 6 individuals were diagnosed as being dependent on drugs on admission to prison whereas in 1983 around 300 (6% of the prison population) were drug abusers. These results have led to the [SNBTS] refraining from visiting prisons to obtain blood for transfusion purposes.<sup>213</sup>

**26.138** On 24 March 1986, in a reply to a Parliamentary Question on blood donations from prisoners, Baroness Trumpington, Under-Secretary of State, DHSS, stated:

Regional Transfusion Directors [in England and Wales] have clinical responsibility for the acceptance of blood donors. They do not collect blood from groups known to be at risk from certain diseases.

I am advised that RTDs in England started to phase out collecting blood from prisoners in 1980. Among the factors which they took into account was the large number of donations from prisoners which routine screening for hepatitis showed could not be used. The available tests are not able to screen for all types of hepatitis virus or the presence of the virus in the early stages of the disease. The primary concern of the [NBTS] must be to protect recipients of donated blood.<sup>214</sup>

### **Evidence relating to drug use among prisoners**

**26.139** The chronological review of the evidence available to the Inquiry discloses a belief, expressed from time to time in the later 1970s and early 1980s, and perhaps most clearly by Dr Mitchell in a passage quoted later, that prisoners were ‘not in the drug addict class...’. There were drug addicts among paid blood donors, hence their exclusion from donation for example in the USA. There were drug addicts among young adult males, as reported for example by Dr Helske in Finland. In 1972, however, in England and Wales and in Scotland, even among those prisoners who were HBsAg-positive, it appears that none were thought to be drug addicts. A similar picture was presented as late as 1983. There could have been an issue over the classification of an individual as a drug ‘addict’. Custodial sentences for possession of controlled drugs, with or without intent to supply, were not uncommon after the commencement of the Misuse of Drugs Act 1972, however, and a frequent plea heard in courts where an intent to supply was admitted or proven, was that the individual had been dealing to ‘feed a habit’. Anecdotal evidence suggested that drug use among prisoners might have been a material factor. The belief that prisoners were not in ‘the drug addict class’ appeared counterintuitive and it was necessary to investigate the official reporting of data.

### ***Annual Reports by the Secretary of State for Scotland***

**26.140** The Secretary of State for Scotland presented annual reports to Parliament on prisons and other penal institutions in accordance with section 5 of the Prisons (Scotland) Act 1952. The annual reports dealt with various matters including the health of prisoners and the incidence of drug dependency among prisoners.<sup>215</sup> The reports generally, but not invariably, gave numbers for those prisoners with a continuing dependency on drugs at the time of admission, rather than those prisoners who had ever used drugs intravenously. The reports are therefore likely to have underestimated the numbers presenting risk of transmission of infection for that among other reasons, such as those given by Dr Brookes based on her previous experience.<sup>216</sup>

---

<sup>215</sup> For a full list of the matters covered in the annual reports, see the contents page of the 1975 report [PEN.012.0535] at 0538.

<sup>216</sup> Letter dated 18 July 2011 from Ms Robson of the Scottish Government Legal Directorate to the Inquiry [PEN.012.1904] at 1905, para 3, in response to a list of questions by the Inquiry [PEN.012.1782]

**26.141** The data returned for the years 1970 to 1985 were:

**Table 26.4: Secretary of State’s Annual Report to Parliament of recorded cases of dependence on drugs in prisons and other penal institutions**

Reference period and date	Hard drugs			Other drugs
	Males	Females	Total	
1970: June 1978 <sup>217</sup>	[16]		16	
1971: June 1978 <sup>218</sup>	[16]		16	
1972: June 1978 <sup>219</sup>	[12]		12	
1973: June 1978 <sup>220</sup>	[6]		6	
1974: June 1978 <sup>221</sup>	[6]		6	
1975: June 1978 <sup>222</sup>	[5]		5	
1976: June 1978 <sup>223</sup>	21	11	32	
1977: December 1978 <sup>224</sup>	7	8	15	
1978: December 1979 <sup>225</sup>	11	8	19	
1979: October 1980 <sup>226</sup>	5	9	14	
1980: November 1982 <sup>227</sup>	6	12	18	51
1981: August 1982 <sup>228</sup>	51	35	86	35
1982: September 1983 <sup>229</sup>				
1983: November 1984 <sup>230</sup>			1163	
1984: November 1985 <sup>231</sup>			1160	

- The 1976 report did not distinguish males and females for the earlier years.
- The 1982 report did not disclose figures but noted ‘steadily increasing numbers of admissions ... who have been abusing drugs’.

<sup>229</sup> 1982 Report [PEN.012.0693] at 0696. Although figures were not disclosed, the Report noted the ‘steady increase’ in admissions of those using drugs. ‘Nearly all’ of these prisoners were reported to have been using heroin or other opiates.

<sup>230</sup> 1983 Report [PEN.012.0715] at 0718. Again, ‘nearly all’ of these prisoners were reported to have been using heroin/opiates.

<sup>231</sup> 1984 Report [PEN.012.0734] at 0740

**26.142** The data were not returned consistently and only the broadest of pictures is painted by the totals of all cases.

**Figure 26.1: Recorded cases of drug dependence in Scottish Penal Institutions, 1970–1985**

**26.143** It appears that it was not until the early 1980s that the reports showed a significant and continuing increase in drug dependence among prisoners. In the final two years, growth was exponential. There was no evidence before the Inquiry that the contents of these reports, including in particular the evidence of drug use by prisoners, were shared by the SHHD with the SNBTS. The narrative comment in the reports is instructive as to changing perceptions, however.

**26.144** The annual report for 1976 (presented to Parliament in June 1978) commented that all but one of the prisoners dependent on hard drugs were adult inmates.<sup>232</sup> The 1977 report (presented to Parliament in December 1978) stated that the number of recorded cases of dependence on hard drugs had fortunately not continued to show the marked increase recorded in the previous year.<sup>233</sup> The 1978 report (presented to Parliament in December 1979) recorded numbers without comment.<sup>234</sup> The 1979 report (presented to Parliament in October 1980) stated:

Drug dependency diagnosed within Scottish penal establishments, fortunately, does not present a serious problem and there has been little change in the numbers requiring treatment in recent years.<sup>235</sup>

<sup>232</sup> 1976 Report [PEN.012.0605] at 0607

<sup>233</sup> 1977 Report [PEN.012.0612] at 0615

<sup>234</sup> 1978 Report [PEN.012.0619] at 0621

<sup>235</sup> 1979 Report [PEN.012.0625] at 0627

**26.145** The 1980 report (presented to Parliament in November 1981) commented:

The diagnosis of dependence on hard drugs shows little variation over recent years, 18 ... of which 6 ... were males and 12 ... females. However, 51 ... were recorded as dependent on other drugs. There are many more admissions who, if not actually dependent, have a clear history of drug abuse.<sup>236</sup>

**26.146** The impression conveyed to Parliament by the reports to this date was that drug dependence among inmates of penal institutions was not a serious problem in Scotland. Only in the 1980 report was there an indication that the recorded data may not have represented the full extent of the problem of past or current use of drugs by prisoners.

**26.147** The 1981 report (presented to Parliament in August 1982) stated:

The large reservoir of hepatitis infectivity in the world is now appreciated and medical, dental and nursing staff in penal institutions are aware of the special risk categories which come under their care.<sup>237</sup>

....

The increasing misuse of drugs throughout the country is well publicised and prison medical officers are reporting an increase in the number of admissions who have been abusing drugs. There has, this year, been a marked increase in the number of inmates recorded as being dependent on hard drugs such as heroin, 86 ... of which 51 ... were male and 35 ... female. There has, conversely, been a slight fall in the number of cases recorded as being dependent on other drugs, 35 ... 7 ... male and 28 ... female.<sup>238</sup>

**26.148** The 1982 report (presented to Parliament in September 1983) did not provide figures but commented in general terms on the growing problem:

There is no doubt that over the past few years we have seen steadily increasing numbers of admissions to local prisons who have been abusing drugs. These drugs have, unfortunately, usually been hard drugs such as heroin and diconal [a different opioid drug]. In many cases there are obvious signs of self injection and others willingly give a relevant history. This reflects the well publicised, regrettable and dangerous pandemic of drug abuse taking place at present.<sup>239</sup>

**26.149** The 1983 report (presented to Parliament in November 1984) stated:

- The general health of inmates has been satisfactory, but the number who seek medical attention is large and has shown a steady increase over the past few years, almost doubling over the past 10 years ....<sup>240</sup>
- These rising numbers are not the result of any marked changes in disease pattern, but they do perhaps reflect the increasing number of inmates with personality disorders, with a history of alcoholism and, over the past 2 years, the rapidly increasing number who have been misusing drugs of addiction

<sup>236</sup> 1980 Report [PEN.012.0631] at 0640

<sup>237</sup> 1981 Report [PEN.012.0669] at 0672

<sup>238</sup> Ibid [PEN.012.0669] at 0673–74

<sup>239</sup> 1982 Report [PEN.012.0693] at 0696

<sup>240</sup> 1983 Report [PEN.012.0715] at 0716

prior to admission. The psychological and physical morbidity associated with these conditions lead to considerable demands upon medical and nursing staff.<sup>241</sup>

- Drug Abuse: 490 inmates were recorded as being dependent upon drugs at the time of reception or had recently misused drugs of addiction. The dramatic rise in misuse of narcotic drugs in the UK has been well publicised and this is mirrored in the admissions to our local establishments. Nearly all have been using heroin and most have been multiple drug abusers, involving combinations of heroin, morphine, methadone and sometimes cocaine. Misuse of cannabis, amphetamines and barbiturates is often reported, as is the misuse of dipipanone [another name for diconal] and LSD.<sup>242</sup>
- *Infective Hepatitis*:... The incidence of carriers and suspected carriers of Hepatitis B infection in the general community is well recognised and it is realised that penal establishments, with an increasing number of admissions who are drug abusers, will contain their share of possible carriers.<sup>243</sup>

**26.150** The 1984 report (presented to Parliament in November 1985) stated:

- The alarming increase in the use of narcotic drugs in the United Kingdom is mirrored in the number of persons admitted to penal establishments who are identified as having recently used dangerous drugs of addiction. In 1984 some 1160 persons admitted to Scottish penal establishments had been involved in drug abuse compared with 490 in 1983. Almost all had been using heroin, although many had also been abusers of other drugs.<sup>244</sup>
- Of this number recorded, 935 were males and 228 females. Almost all had been using heroin, although many had also been multiple drug abusers.<sup>245</sup>
- The increase in the incidence of hepatitis over the past few years is, of course, associated with the increase in intravenous drug abuse. Wherever possible potential carrier states are identified and all sensible precautions to protect staff and inmates are taken.<sup>246</sup>

**26.151** Taken together these reports express the impression conveyed by the figures quoted. They do so particularly in the comments made. They also represent a sudden and rapid increase in the incidence of recorded illicit drug use beginning in the first half of the 1980s. For present purposes there are some obvious concerns about the relevance of the data, especially for the earlier periods. Drug dependency on admission may give a poor indication of a history of relevant drug use up to that point in the individual's life. Reported drug dependency may have been less than actual drug dependency (especially before methadone was readily available on prescription as a substitute for heroin). A drug habit that did not require medical intervention would not have been captured in clinical records. The data appear to have been the best available in official records at the time, however.

<sup>246</sup> Ibid [PEN.012.0734] at 0750

### *Annual reports by HM Chief Inspector of Prisons for Scotland*

**26.152** The post of Her Majesty's Chief Inspector of Prisons for Scotland was created in 1980 and the Inspectorate of Prisons for Scotland began operations in 1981. The Chief Inspector's 1981 report (presented to Parliament in August 1982) contained no reference to drug use among prisoners,<sup>247</sup> nor did the 1982<sup>248</sup> or 1983<sup>249</sup> annual reports. The Chief Inspector's 1984 annual report (presented to Parliament in October 1985) contained only a brief reference to drug use, in particular in relation to smuggling drugs into prisons during prison visits.<sup>250</sup>

**26.153** On the face of the official records, they appear to give some support for the views expressed by Dr Mitchell and others that until the AIDS era there were no, or at least few, drug addicts in Scottish prisons. With the benefit of hindsight one might question the accuracy and the relevance of the data published and to look at collateral sources of information, such as records of criminal proceedings related to drug use and trafficking for insight into the actual level of use giving rise to the risk of transmission of infection. Later studies were to show that recreational drug use in the United Kingdom increased steadily in the 1960s and into the 1970s.<sup>251</sup> Given the relatively high prevalence of viral infection among prisoners, this would have been significant information in the 1970s and early 1980s. This was not known at the time, however. Based on the official records, drug use could not be shown to have been a material factor aggravating the risks associated with collecting blood in Scottish prisons. The desirability or undesirability of collecting blood in prisons has to be judged on more general grounds.

### *Blood supply and prison collections*

**26.154** As noted earlier, the percentage of total blood donations in Scotland collected from prisons fell from 2.38% in 1975 (5915 of 248,558 donations) to 0.11% in 1984 (342 of 308,617 donations), with an annual average over that period of 1.097%.<sup>252</sup> In view of the international guidance that need and supply were factors that might affect local choices, a question arises whether an adequate supply of blood could have been maintained had collection from prisons stopped at any time between 1975 and 1984.

**26.155** In general, in Edinburgh and the south east of Scotland there was a surplus of red cells, at least in the early 1980s, as a result of the drive to collect plasma for fractionation.<sup>253</sup>

**26.156** In contrast, in Glasgow and the west of Scotland, which accounted for almost one half of all of the blood collected in Scotland, there were problems from time to time, in particular during holiday periods, in collecting enough blood from local supplies to meet clinical demand.<sup>254</sup> As the evidence of Mrs Prior indicated, prison visits in Glasgow took place principally during holiday periods.

<sup>247</sup> 1981 Report [PEN.012.0645]

<sup>248</sup> 1982 Report [PEN.012.0677]

<sup>249</sup> 1983 Report [PEN.012.0701]

<sup>250</sup> 1984 Report [PEN.012.0720] at 0728

<sup>251</sup> See paragraph 26.201 below.

<sup>252</sup> In fact, these figures are likely to be slightly higher as the number of prison donations collected from the North of Scotland RTC (Inverness) are not available as a result of records being destroyed in a flood – see para 1 of the SNBTS paper 'Blood collection 1975–1991' [PEN.010.0003]

<sup>253</sup> Dr McClelland – Day 64, pages 51–52

<sup>254</sup> See, for example, Professor Cash's letters to Dr Mitchell of 30 December 1982 [SNB.003.7020], 16 January 1987 [SNB.011.3355] and 15 January 1990 [SNB.013.6496]

**26.157** In a letter dated 30 December 1982 to Dr Mitchell, Professor Cash suggested that any difficulties in ensuring a sufficient supply of blood for cardiac surgery in Glasgow could be met by obtaining red cell concentrates, or even whole blood, from other SNBTS Regional Centres. Professor Cash noted:

Whilst I recognise that figures can be misleading, particularly in the context of fluctuating supply and demand for blood and blood products, the facts are that in the year ending 31st March, 1983 the SNBTS as a whole outdated more than 40,000 donations of whole blood and 35,000 donations of red cell concentrates. It may well transpire that the periods in the year when the West is short and the periods when other regions are short are identical. This topic, however, has not been explored and, in view of the significant potential implications contained in your letter to David Wheatley, I believe the time has come for me to place the matter on the Agenda for our next Co-ordinating Group meeting.

....

Common sense demands, previous experience points to fact, that real co-operation between the Regional Centres of the SNBTS is an essential option that needs to be explored continuously. The public, not to mention the Scottish blood donors, would be disturbed to discover that because of management failings patients in one part of Scotland were suffering because of a lack of blood and in an adjacent city blood was being discarded.<sup>255</sup>

**26.158** However, when the matter was considered at the meeting of the SNBTS Directors' Co-ordinating Group on 22 February 1983, it was noted that Dr Mitchell indicated that he preferred to cope from within his own region.<sup>256</sup>

**26.159** In a letter dated 28 January 1985 to Dr Bell, SHHD, Professor Cash noted that:

The SNBTS currently outdates 30% of its shelveable blood intake (90,000 donations/year). The reasons for this are well known to you – it reflects, primarily, the fact that we are largely plasma driven.

The SEBTS (with the knowledge of the CSA) is now regularly supplying the Edgware RTC [in London] with red cell concentrates.<sup>257</sup>

**26.160** The themes of occasional blood shortages in Glasgow, excess blood products in Edinburgh and Glasgow's communication with other centres arose again in the winters of 1986–87<sup>258</sup> and 1989–90.<sup>259</sup>

**26.161** By way of explanation for the situation in the west, Professor Cash stated in his written evidence to the Inquiry that:

[I]t is worth pointing out that the annual blood collection figures per million of population in the West was significantly below all other regions in Scotland throughout the 1980s. Thus supply difficulties for red cell was [sic] a not

---

<sup>255</sup> Letter [SNB.003.7020]

<sup>257</sup> Letter [SNB.013.4238]

<sup>258</sup> See letter dated 16 January 1987 from Professor Cash to Dr Ruthven Mitchell [SNB.011.3355]

<sup>259</sup> See letter dated 15 January 1990 from Professor Cash to Dr Mitchell [SNB.013.6496] and subsequent letters between Dr RJ Crawford, Glasgow BTS, and Professor Cash dated 29 January 1990 [SNB.014.1589] and 6 February 1990 [SNB.005.2159]

infrequent anxiety for colleagues in the West where poverty and deprivation were significant challenges for those responsible for the blood collection programmes. It is almost certain that it was never a problem for Edinburgh or any other SNBTS region.<sup>260</sup>

**26.162** In his evidence to the Inquiry Dr Mitchell was asked to comment on the particular benefit to the West in collecting donations from prisons. He replied:

Well, it depended at what time of the year. Clearly, every transfusion centre that I have ever worked in has shortages. There is no question that that does occur. It occurs for a variety of reasons. Sometimes it is due to ... holiday times, especially festive seasons, certainly around the West of Scotland. It may also be due to problems with transport, problems with weather and so on. These can easily upset a session or a set of sessions.

So when people are going away or things don't happen then you are left with a major problem and that's one of the reasons that one went to prisons during times when you could anticipate that there might well be shortages.<sup>261</sup>

**26.163** In his evidence to the Inquiry, Dr McClelland was asked whether stopping collection from HMP Saughton caused any problems to supplies in the region. He replied:

It did not, and we would not have expected it to do so because our blood collection programme at that time was firmly driven by the requirement for plasma to be used in the preparation of Factor VIII, you know, in the effort to achieve self-sufficiency with an ever rising utilisation of Factor VIII.

So we actually had a superabundance of red cells. The reason for that is that the majority of the plasma which was provided from our centres to the fractionation plant was collected, at that time, in the form of whole blood from which it was then separated. So we had had a lot of red cells and we shipped the plasma off. Over this sort of period we quite frequently supplied red cells to centres south of the border. We regularly supplied them to one of the London centres for quite a period because we were concerned about ... inappropriate wastage of cells that had been donated.

So it didn't cause a problem in the south east region.<sup>262</sup>

**26.164** Dr Mitchell was asked whether stopping the collection of blood from prisons in the west of Scotland in early 1984 caused any difficulties in respect of shortages of blood and replied, 'I think the answer to that is: yes from time to time. Most of the time one could cope. In fact, pretty well all of the time you could cope'.<sup>263</sup> Dr Mitchell agreed with the suggestion put to him that stopping collection from prisons did not cause any insurmountable problems with the blood supply.<sup>264</sup>

**26.165** Professor Cash was asked whether a decision in 1975 to stop prison collections in Scotland was likely to have caused any insurmountable problems in the supply of blood. He replied:

---

<sup>260</sup> Professor Cash's Witness Statement [WIT.003.0120] at 0122

<sup>261</sup> Day 9, page 162

<sup>262</sup> Ibid pages 67–68

<sup>263</sup> Ibid page 163

<sup>264</sup> Ibid page 164

[I]t would in my experience have required a little less autonomy, a little more cross-regional support, when times got difficult. But if you take the total input of red cells to the whole of Scotland, I don't believe that 1 per cent would have – we could easily have coped with it.<sup>265</sup>

### *The role of government*

**26.166** It appears that the Home Office favoured the collection of blood in prisons. That seems clear from the minutes of the meeting of the English directors on 26 September 1973,<sup>266</sup> discussed above, where it was noted that the Home Office should be informed before any action was taken to discontinue collection in prisons, and from the DHSS memo dated 23 August 1983 which referred to the need for close liaison with the Home Office, 'since they have in the past been very much in favour of blood donation by prisoners.'<sup>267</sup>

**26.167** In addition, in her written evidence to the Inquiry Dr Brookes stated that, when she arrived in Scotland in 1981 as Director of the Dundee RTC, she understood, based on her experience working in England, that it was long-standing government policy that the BTS should visit prisons to 'permit prisoners to make some restitution to society' and to 'do something which many of the community did, to help their return to normal life after release'.<sup>268</sup>

**26.168** Dr Graham Scott, former Deputy Chief Medical Officer, SHHD, was asked about the consideration, if any, given by the SHHD between 1975 and 1984 to the practice of collecting blood from penal institutions, the risk of NANB Hepatitis from such donations and whether the practice of collecting blood from such institutions should continue. In his written response to the Inquiry he stated, 'I do not know whether SHHD gave any consideration to this issue; I do not recall being asked to consider it. In any event, I would not have considered it appropriate to interfere with SNBTS practices'.<sup>269</sup> During his oral evidence to the Inquiry he was asked what he meant by the statement that he would have not considered it appropriate to interfere with SNBTS practices and replied:

I wouldn't have considered it appropriate to question their decisions about taking donations from prisons. I considered them to be excellent scientific individuals and well able to judge what they were doing in their individual circumstances and their individual reason. And in their areas, they would know what was going on. I would not have interfered with that.<sup>270</sup>

**26.169** Despite the evidence that the Home Office in London had been in favour of collecting blood from prisons, Dr Scott was not aware that the SHHD had expressed any views in favour of collection in prisons, which he considered to be 'a matter for the SNBTS Directors'<sup>271</sup> who were 'in the best position to make informed decisions based on local circumstances'.<sup>272</sup> He was asked whether, in the 1970s and early 1980s, the SHHD or ministers encouraged donations in prisons and replied in the negative. Dr Scott was also asked whether between 1975 and 1984 he or the SHHD had any view on the practice

<sup>265</sup> Day 10, page 73. See also Professor Cash's Written Statement on blood shortages [PEN.011.0066]

<sup>269</sup> Dr Scott's Witness Statement [WIT.003.0019] at 0020

<sup>270</sup> Day 11, page 130. That answer requires to be considered against the background that Dr Scott, like his other medical colleagues at SHHD, was a public health doctor, and was not an expert in any one medical discipline such as transfusion medicine.

<sup>271</sup> Day 11, page 134

<sup>272</sup> Dr Scott's Witness Statement [WIT.003.0019] at 0021

of collecting blood from prisons. He replied, 'I don't have a view on this. In my opinion, this was a matter for SNBTS'. Nor was he prepared to offer a view on the practice with the benefit of hindsight.<sup>273</sup> He stated, 'if I had told the SNBTS directors what to do with regard to ... donors selection, I would have been told to mind my own business'.<sup>274</sup> SNBTS Directors, as Consultants in the NHS, 'were in the position to make their own decisions'.<sup>275</sup> In Dr Scott's view, the SNBTS Directors could not expect to get a lead from either the SHHD or the DHSS on whether the practice of collecting blood from prisons was acceptable.<sup>276</sup>

**26.170** In his written statement to the Inquiry, the position of Dr McIntyre, Principal Medical Officer (PMO) was similar to that of Dr Scott.<sup>277</sup> Dr McIntyre stated:

The collection of blood from penal institutions was an established practice by the time I took responsibility for blood policy as PMO in charge of the public health group.

....

I did not take part in any discussions regarding the continued collection of blood from penal institutions. I am not aware of my colleagues having been involved in such discussions. This was really an issue for the Regional Transfusion Directors to address.

....

We knew that SNBTS were running the show and there was felt to be no need for us to interfere. SHHD did not set policy for SNBTS in this area.

....

I do not remember SHHD or Ministers encouraging donations in prisons.<sup>278</sup>

**26.171** In a written statement provided to the Inquiry, Mr John Wastle, an administrative officer in the SHHD, stated:

I was aware that the Home Office had encouraged the collection of blood from prisons in England but I was never aware that the "Home" side of SHHD (which was roughly the Scottish equivalent of the Home Office) had sought to give such encouragement in the 1970s and early 1980s. Similarly, I am not aware that the "Health" side of SHHD or Ministers ever gave such encouragement. My understanding in 1982-83 was that this was an operational consideration for the individual RTC Directors and this, I think, is reflected in the differing positions which they had taken on the issue.<sup>279</sup>

**26.172** Professor Cash was asked whether the SHHD ever sought to influence or encourage the collection of blood in prisons in Scotland and replied, 'No, I'm not aware ... Encouraged? No, I'm not aware. Nor am I aware that they discouraged either'.<sup>280</sup> He went on:

<sup>278</sup> See, generally, Dr McIntyre's Witness Statement [WIT.003.0013]

<sup>279</sup> Mr Wastle's Witness Statement [PEN.010.0316] at 0323–24

<sup>280</sup> Day 10, page 65

I would add that there is this strong tradition ... that these matters were under very much the governance of DHSS and I suspect, to be fair to my Civil Service colleagues in Scotland ... that they were waiting for a judgment to come up from London on this and they waited.<sup>281</sup>

**26.173** Professor Cash was further asked who he thought was best placed to consider whether it was appropriate to collect blood from prisons in Scotland. He replied:

In retrospect, I have no doubt it should have been SNBTS but at that time these matters – we broke away eventually in Scotland at that time. These matters, the question of donor selection, were very much in the hands of the DHSS and I think we eventually recognised that this wasn't right.<sup>282</sup>

**26.174** Dr McClelland was asked if he was aware whether the SHHD ever sought to influence or encourage the SNBTS in the collection of blood from prisons. He replied:

I'm not aware of the [SHHD] expressing a view either way, either for or against .... [T]he transfusion directors' meetings were regularly attended by a senior person, a medical person, from the department and they received all the papers and so on. They would have been party to any discussions and would have had ample opportunity to express a departmental view, had they wished to do so.<sup>283</sup>

**26.175** Dr McClelland was asked who was best placed to decide on matters of donor selection policy, the SHHD or the SNBTS, and replied:

I think it probably was primarily an issue for the [SNBTS]. Had there been a view that there was, as it were, a non-medical, like a sociological or welfare reason, to encourage donations in prisons, which certainly is the strand that emerged from the consultations in London, that, I think, would have been an issue for the Department of Health because it certainly is not a health issue for the transfusion service.<sup>284</sup>

### *Why prison collections stopped*

**26.176** In his evidence to the Inquiry Dr McClelland was asked why his region stopped prison collections in 1981. He explained that he had recently spoken with his former regional donor organiser who had reminded him that the donor organiser:

[A]ctually felt it was just an unsuitable environment in total.

It was almost more that concern, plus the specific concerns that really, for lots of very good reasons, we could not rely on getting completely clear transparent answers from prisoners ....

So it would not be correct for me to say that we were worried about hepatitis in the prisons. We were worried about the totality of the environment and I was certainly aware that infection with hepatitis and related viruses was a problem in prisons. I was certainly aware of that information in the United States. So it was a sort of complex of things that led us to this decision.<sup>285</sup>

---

<sup>281</sup> Ibid pages 65–66

<sup>282</sup> Ibid page 67

<sup>283</sup> Day 9, page 83

<sup>284</sup> Ibid pages 83–84

<sup>285</sup> Ibid pages 32–33

**26.177** In answer to a question as to whether the concerns of his regional donor organiser centred on it being unfair on the blood transfusion service staff to expect them to conduct sessions in prisons, Dr McClelland replied, 'I think the BTS found it quite a threatening environment'.<sup>286</sup>

**26.178** Dr McClelland also explained that he could find no evidence that a policy decision was taken by his region not to visit prisons again. Indeed, his response to the Medicines Inspectors in January 1983 had been to the effect that while no sessions in prisons or borstals had been held for two years, such collections might be used in an emergency.<sup>287</sup> He gave the following evidence:

We never did go to prisons again. Having tried to reconstruct this, I find no evidence that we recorded a policy decision that we will stop collecting blood in penal institutions; we just stopped doing it. We informed the contact person, who I think was the Director of Saughton ... that we were not making any further appointments, and in fact we had several representations from them subsequently to come back and run sessions and we did not do that.

I honestly cannot remember now why we did not, as it were, make it a formal policy. I have tried very hard to find any evidence of that, but, as I say, the actions are that we did not ever return and we did not book any further sessions and we never felt any need to do so.<sup>288</sup>

**26.179** In his evidence to the Inquiry Dr Mitchell stated that 'the question that tipped the balance, as far as Glasgow was concerned, was the advent of an incurable disease at that time, called HIV'.<sup>289</sup>

**26.180** Professor Urbaniak decided to attend the collection sessions scheduled, before his tenure, for HMP Craiginches on 7 July 1983 and HMP Peterhead on 28 July 1983. Following his visits he concluded that in the light of the potential for undesirable peer pressure, the potential for an unreliable medical history to be provided and difficulties with confidentiality, the practice should end in the NE region. He also had concerns, on behalf of his all-female donor staff team, at their working in such an environment. No further prison sessions took place in the NE region after 28 July 1983. A cluster analysis, subsequently undertaken by him, revealed both prisons to be HBV 'hotspots'.

### *Evidence relating to the question whether prison collections should have stopped earlier*

**26.181** While Dr Gillon was not working in the field of blood transfusion at the time, his impression was that 'the focus on prisons had been largely in relation to Hepatitis B and the feeling was that testing had reached the level of sensitivity that took that off the radar to some extent'.<sup>290</sup> That appears to have been the position by about 1975 when the third generation tests for HBsAg was thought to have significantly reduced HBV infection among blood transfusion recipients. Relatively sensitive and accurate tests for HBV were beginning to be widely available at that time and tests for HAV soon followed.<sup>291</sup> Several

<sup>291</sup> A practical test for HAV was not available in Scotland until 1978.

groups reported in the following year that the majority of patients with clinically diagnosed post-transfusion hepatitis tested negative for infection with HAV and HBV.<sup>292</sup>

**26.182** From 1976 to 1977, the focus began to change towards NANB Hepatitis. However, tests for HBsAg continued to improve. In 1976, there was controversy between Dr Wallace and SHHD over the relative effectiveness of Reverse Passive Haemagglutination and Radioimmunoassay, two widely available HBsAg tests,<sup>293</sup> against a background of growing confidence in the effectiveness of the screening process to reduce, if not totally eliminate, the risk of transmission of HBV. Doubts began to emerge as the investigation of chronic liver disease widened in the later 1970s. For example, the Haemophilia Centre Directors' Hepatitis Working Party report dated 20 August 1978 on the pilot project to investigate the incidence of chronic liver disease in patients treated with Hemofil in 1974–75, expressed doubts about the screening tests for HBsAg.<sup>294</sup>

**26.183** It is necessary to keep a sense of historical perspective in discussing the question of the exclusion of prison donors. A view that might have been taken on the basis of understanding of the accuracy of assays before NANB Hepatitis was known would require revision after that stage.

**26.184** Dr Mitchell was asked whether, with the benefit of hindsight, blood should have been collected from prisons in Scotland in the late 1970s and early 1980s and replied:

I don't think there was any major reason not to do it .... It was quite clear that prisoners are human beings. They have a right to give blood like anybody else. It is a civic duty. Many of them felt that it was important that they should do that. Many of them continued when they left prison. Some had been giving before they went into prison. Nothing very much had happened in the interval to suddenly decide against one particular group, it would be difficult to sustain against the idea "Well, why are you discriminating against us?"<sup>295</sup>

**26.185** Dr Mitchell was asked whether the following factors altered his view: namely, the higher prevalence of Hepatitis B in the prison population, the likelihood that the initial Hepatitis B tests did not detect all donations that were positive for Hepatitis B and, in the late 1970s/early 1980s, the emergence of NANB Hepatitis and there being no tests to exclude that disease. He replied:

No, not really. I think the question of the advent of [NANB Hepatitis] was something which was badly understood in the UK. Something which wasn't entirely – the whole epidemiology of it wasn't understood. And whether it would be confined to prisoners who we already knew were not in the drug addict class and so on, like anybody else, we had no reason to believe that they were any different, except for the statement that's made that there were social differences between prisoners, for reasons of close contact with others, incarceration and so on.

....

[NANB Hepatitis] was a diagnosis of exclusion in most cases. There are very few cases in the UK that I was aware of at that time. We seldom got reports from

<sup>292</sup> Alter et al, 'Clinical and serological analysis of transfusion-associated hepatitis', *The Lancet*, 1975; 2:838–841 [PEN.002.0836]

<sup>295</sup> Day 9, pages 164–165

hospitals, “Oh, we have got a case of post-transfusion hepatitis” of any kind. That was unusual. They knew to report that.

....

So I’m sure they would have let us know but they didn’t and you would take it, well, it wasn’t all that important.<sup>296</sup>

**26.186** Dr Mitchell’s evidence on the reported incidence of NANB Hepatitis was similar to the evidence of Professor Hayes. (See Chapter 15, *Knowledge of Viral Hepatitis 2 – 1975 to 1985*, paragraph 13.34.)

**26.187** Dr McClelland joined the SNBTS in 1977 and became a Regional Director in 1979. He was not aware of Dr Yellowlees’ letter of 1 May 1975 when he joined the service. His observations on reading the letter later have been set out in paragraphs 26.84–26.85 above. He found the letter surprising but later he qualified that evidence by saying: ‘That is a personal view. It says absolutely nothing about what I might or might not have thought about it had I read it 30 years ago ...’.<sup>297</sup>

**26.188** Dr McClelland was asked why he continued to collect blood from prisons until 1981 if he found the advice contained in Dr Yellowlees’ letter of 1 May 1975 ‘surprising’ and replied:

I think that we should have stopped. I think we should have stopped sooner. I think it was a matter of focussing on, you know – you come to a complicated new job, you have to decide on which bit of it you are going to focus on and there were many, many preoccupations, like – as will be evident from the medicines inspector’s report, the facilities in Edinburgh were deeply unsatisfactory. There was a huge pressure within the organisation. Really the driving pressure within the organisation was collecting plasma to meet haemophilia requirements, and I think that I, as a director there, was slow off to the mark in realising this.

I don’t wish to defend that but, as you say, you end up not paying attention to all the potential problems simultaneously. This was one that came a little bit later but I think we responded to it. I think that once we sort of started to think about the issue, it became quickly very obvious that we were going to stop.<sup>298</sup>

**26.189** Later, Dr McClelland was asked whether the collection of blood from prisons had been a real issue for him before his regional donor organiser raised it with him and replied:

I don’t think it had. I think I had probably accepted it as the way things were done and probably not directed a great deal of attention to it because I was probably directing my attention to other things.<sup>299</sup>

**26.190** Dr McClelland was asked what his view would have been at the time, had he been asked between 1975 and 1981 whether it was appropriate to collect blood at prisons. He replied:

I think that’s almost impossible to answer. I can’t unlearn. I mean, what may have happened at that time was I would have consulted my colleagues, as

---

<sup>296</sup> Ibid pages 165–166

<sup>297</sup> Ibid page 146

<sup>298</sup> Ibid pages 76–77

<sup>299</sup> Ibid page 79. There, Dr McClelland also agreed with the suggestion that he hadn’t really applied his mind to the collection of blood from prisons as an issue until his new regional donor organiser raised it as an issue when she arrived.

transfusion directors, many of whom had been in post for a long [time] and were highly experienced, and I would have perhaps consulted what, you know, the recommendations from the CMO, or whoever, were. And I might have concluded that, because it was normal practice, because everybody else was doing it and because the CMO said it was fine, I might well have continued – I can't put myself back 25 years in any meaningful way.<sup>300</sup>

**26.191** Dr McClelland gave the following written evidence in respect of the state of knowledge of NANB Hepatitis in 1975:

The importance of the condition [ie NANB Hepatitis] had not at this time been fully appreciated by many concerned with these decisions. Because no causative agent could be identified there was no specific test for NANB and knowledge of the natural history and the epidemiology was lacking. It was not possible to know that individuals could become infected without having evidence of jaundice or indeed any clinical features. Nor could it be known that once an individual was infected their blood could continue to contain the infectious agent for many years in the absence of any symptoms or that some forms of chronic liver disease would eventually be discovered to be caused by chronic infection.<sup>301</sup>

**26.192** Dr McClelland was taken to the international guidance documents discussed earlier and was asked whether the international guidance was consistent or inconsistent with the practice of collecting blood in prisons. He replied:

I think it certainly calls the practice into question, that some of the guidance in these documents would, I think, fairly clearly identify [the] prison population as potentially at least a population from which it is inadvisable to collect blood donations.<sup>302</sup>

**26.193** Professor Cash agreed with five propositions that were put to him. These were that: (i) initially, Hepatitis B screening tests were relatively insensitive in the sense that they did not detect all or perhaps even most positive donors; (ii) there came a point, perhaps around the mid 1970s, when Hepatitis B screening tests were more sensitive and probably did detect most Hepatitis B positive donors; (iii) around that time, there appeared to be a blood-borne non-A, non-B Hepatitis agent or agents; (iv) there was an increased prevalence of Hepatitis B among prisoners; and, (v) Hepatitis B is a blood-borne virus.<sup>303</sup> Professor Cash was asked whether it followed from these five propositions that there may also have been an increased prevalence of NANB Hepatitis among prisoners and replied, 'I agree that there may have been, yes'. He agreed with the suggestion that these five propositions should at least have given pause for thought in the mid to late 1970s as to whether blood should continue to be collected from prisons.<sup>304</sup>

**26.194** Professor Cash was asked, if one had regard to those five propositions and had paused for thought in the mid- to late-1970s to consider whether blood should continue to be collected from prisons, whether he could say what the likely conclusion ought to have been. He replied:

---

<sup>300</sup> Ibid pages 77–78

<sup>301</sup> Dr McClelland's Witness Statement [WIT.003.0072] at 0085

<sup>302</sup> Day 9, page 130

<sup>303</sup> Day 10, pages 106–108

<sup>304</sup> Ibid page 108

I find that very difficult to answer .... I really don't honestly know ... in 2011. Again, with the power of the retrospectoscope [ie the benefit of hindsight] I would probably say they should have got out of that and the whole of the transfusion world should have moved, including the commercial people, collecting plasma. But that's a very retrospective view ....<sup>305</sup>

**26.195** Professor Leikola had not seen Dr Yellowlees' letter of 1 May 1975 prior to being asked to assist the Inquiry. On being sent the letter and asked for his comments he replied:

To me, when I read this particular paragraph here on prisons, I agreed with the first sentence. I also agreed with the second sentence that there are various groups with high risks that are extremely difficult to identify. But somehow I don't see that this fact that we can't identify some risk groups would lead to the decision that one group that we can identify should not be excluded from the donor pool. This means that if there are a number of things that we can't do, that doesn't mean that if there is something that we can do, it should not be done. If that group can be clearly identified, as stated here, the prisoners were a group with risk.<sup>306</sup>

**26.196** Professor Leikola confirmed that the introduction of more sensitive Hepatitis B screening tests around 1975 did not alter his opinion that a donor group which was known to carry a greater risk of Hepatitis B should still have been avoided.<sup>307</sup> He was asked whether this was an area in which different experts could reasonably hold different views or whether he considered that it simply would not be a reasonable view that collection in prisons should continue. He replied:

I think that the meaning of introduction of a more sensitive test was interpreted differently by different countries, notably in France, the donations in prisons continued and therefore I think that experts could interpret this differently. However, in the light [of] what was known at that time about Hepatitis B and possibly other viruses, I think this advice of, "Yes, go ahead with prison donations", was probably not correct.<sup>308</sup>

**26.197** He went on:

I would refer to the practice in Finland, where we decided to stop that because the significance of prison donations ... to the blood supply was not significant and therefore we decided to, so to say, play safe and therefore from our perspective this particular recommendation, "Yes, go ahead with prison donations", was not reasonable.<sup>309</sup>

**26.198** Professor Leikola was asked a number of specific questions relating to this topic, which are best set out in turn:

- Asked whether he considered that the practice in Scotland of collecting blood in prisons ought to have been reconsidered at any point in the 1970s or early 80s, he replied:

I think my feeling is that the matter should have been taken on the table and discussed in a logical way. Seeing what are the cons and pros of continuing this

---

<sup>305</sup> Ibid page 109

<sup>306</sup> Day 13, page 46

<sup>307</sup> Ibid page 48

<sup>308</sup> Ibid page 49

<sup>309</sup> Ibid page 50

long practice .... However, the impression that I have received from reading these different documents that you sent me is that this matter was really not taken into serious consideration during the late 1970s up until 1981 and of course then 1983.

So my impression – and this is just my impression from reading these documents – is that this tradition went on without really being seriously considered whether it should now be stopped because of various facts that had been published during the 1970s.<sup>310</sup>

- Asked what the conclusion ought to have been had the matter been considered in the 1970s and early 80s, he replied:

In my opinion, that should have been stopped, not necessarily ... from one day on, but sort of faded away, so that it would not have caused very much publicity and the impression of not taking prisoners as human beings. But the conclusion would be that I think it would have been reasonable to stop this old practice.<sup>311</sup>

- Asked whether it was reasonable to continue the practice in the 1970s and early 80s, he replied:

In these circumstances, where, if I'm not mistaken, it was not seriously discussed, then I think that it was reasonable to understand that it went on, even though in my opinion it should have been seriously discussed and then made the conclusion that, no, it's much better not to go to prisons.<sup>312</sup>

- Asked, given that Hepatitis B and NANBH were considered to be blood-borne viruses and studies had shown a higher prevalence of Hepatitis B among prisoners, whether could one reasonably have predicted in the late 1970s that there might also be an increased prevalence of NANBH among prisoners, he replied:

At least in retrospect one would say that one could have seen this connection and drawn that kind of conclusion.

....

Just because it appeared then, on the basis of the American studies, that the non-A non-B, at least in 1977/78, is a blood-borne virus or viruses and very likely to be a virus. So if Hepatitis B is a blood-borne virus, then it is reasonable to think that the inmates would have also higher prevalence of this new, unknown virus.

....

Because the ways of acquiring the virus seemed to be quite similar.<sup>313</sup>

- Asked, given that the initial understanding was that NANB Hepatitis was a clinically benign disease, whether that was a material consideration when deciding whether collection in prisons should continue, he replied:

---

<sup>310</sup> Ibid pages 80–81

<sup>311</sup> Ibid page 81

<sup>312</sup> Ibid page 81

<sup>313</sup> Ibid page 82

I think that it influenced, in the background, the decision.

....

But once it became clear that it is a blood-borne virus and so on, and as was shown in the late 1970s, that indeed it does cause disease and this disease is not necessarily mild, then I think that in a case where there is a possibility to prevent that, even if the measure is not very effective but still if that is possible, then I think it should have been done.<sup>314</sup>

**26.199** Dr McClelland was asked whether there were any lessons that could be learned going forward. He replied that various expert groups had been formed which had worked extremely hard to be aware of information about new or emerging infections and populations at risk and to push for action to be taken quickly. He went on:

What I think is much more difficult is to deal with the problem where you have within a community, a professional communal, a sort of very powerful sort of dome of received opinion, which is sitting over everybody and they have a belief system that this isn't a problem. And therefore even when perhaps some individuals sort of stand up and make a noise and say, "I think there is a problem", there is a very good history of you know, people who actually do see a little bit further ahead, clearly not being – actually they seem to be a nuisance because they get in the way of what we are doing at the moment, and that's really a sort of sociological problem, I'm sure not unique to blood services and it is actually very difficult to deal with.

So I think that the best that we can do ... is wherever possible to encourage attitudes that permit and encourage questioning of things that "everybody knows" and more specifically to look at the mechanisms that we have now and that would include the ... advisory committee on the safety of blood ... the national body charged with informing the ministers of health for UK countries about precisely this type of issue, and try to see that that group is well supported, well resourced, has access to the best intelligence, the best connections for picking up, assessing the importance of things and then making a big noise about it so that somebody does something.

I think these are not exactly revolutionary mechanisms but I don't know that I'm in a position to invent any better solutions. Challenging the received wisdom – because no doubt the received wisdom in the UK was that these things weren't a problem. We were okay because we didn't have paid blood donors and somehow that just made everybody feel – I think it would not be unfair to say that there was a slight sort of sense of superiority because we didn't have paid blood donors in the UK. And that may well have been a factor that sort of blinded people to the fact that we need to look at the totality of our donor populations and be sure that we were sensitive and aware of where perhaps there were risks that were greater and should be seriously questioned.<sup>315</sup>

<sup>314</sup> Ibid pages 95–96

<sup>315</sup> Day 9, pages 132–134

***Evidence in respect of the incidence of Hepatitis C among drug users and prisoners following the availability of Hepatitis C tests***

**26.200** As discussed elsewhere in this Report (see Chapter 16, *Knowledge of Viral Hepatitis 3 – 1986 Onwards* and Chapter 31, *The Introduction of Screening of Donated Blood for Hepatitis C*), the Hepatitis C virus (HCV) was identified in 1988, scientific details of the discovery were published in 1989, tests for HCV subsequently became available and screening of all blood donors for HCV was introduced throughout the UK in September 1991. In short, once tests for HCV became available, studies showed a higher incidence of HCV among those who injected drugs and a higher incidence of HCV among prisoners compared with the general public.

**26.201** In Scotland, all blood donors who were found to be infected with HCV in the first six months of routine testing of all donations for anti-HCV were followed up. Of those HCV-positive donors, intravenous drug use was found to be the most common risk activity (in 39% of the HCV positive donors).<sup>316</sup>

**26.202** In 1999 Dr Sheila Gore and others reported on a study carried out between 1994 and 1996 into the incidence of Hepatitis C among prisoners in five Scottish prisons.<sup>317</sup> Overall, the study found a prevalence of antibodies to Hepatitis C in 20% of inmates, with a prevalence of anti-HCV in 49% of inmates who reported having injected drugs and a prevalence of 3% in inmates who reported not having injected drugs. The study also found that those who began injecting in 1992–96 were less likely to be positive for anti-HCV than those who started before 1992 (31% compared to 55%).<sup>318</sup> The paper noted that:

International data, including from Scotland, suggested that between 60% and 90% of injectors might have hepatitis C antibodies, with between 50% and 90% of them being also RNA positive.<sup>319</sup>

**26.203** In 2002 Dr M. Adekoyejo Balogun and others reported on a study to ‘estimate the background population prevalence of hepatitis C in England and Wales, observe the prevalence over time and assess the extent of infection outside of known risk groups’.<sup>320</sup> In the study, residual sera from samples sent to laboratories for routine diagnostic examination in 1986, 1991 and 1996 were tested for the presence of antibodies to the Hepatitis C virus (anti-HCV).<sup>321</sup> Testing of the serum samples in each of the years gave an estimation of the overall anti-HCV prevalence in the general population of 1.07% in 1986, 0.55% in 1991 and 0.70% in 1996.<sup>322</sup> Having regard to the HCV genotype<sup>323</sup> distribution

<sup>316</sup> Crawford et al, ‘Prevalence and epidemiological characteristics of hepatitis C in Scottish blood donors’, *Transfusion Medicine*, 1994; 4:121 [PEN.002.0582]

<sup>317</sup> Gore et al, ‘Prevalence of hepatitis C in prisons: WASH-C surveillance linked to self-reported risk behaviours’, *Quarterly Journal of Medicine*, 1999; 92:25–32 [LIT.001.3258]. The five prisons were Barlinnie, Perth, Cornton Vale, Low Moss and Aberdeen, and held approximately one half of the adult prisoner population in Scotland. The test used was a ‘recently validated method for detecting antibodies to hepatitis C in saliva (HepCAbs) which had been shown to correlate with the presence of hepatitis C RNA in blood, and thus with hepatitis C carrier status’.

<sup>318</sup> The authors commented that ‘It is possible that the establishment of harm minimization interventions for injectors in the late 1980s, particularly needle or syringe exchange, has led to a reduction in needle sharing, and thus in hepatitis C transmission’. [LIT.001.3258] at 3262

<sup>323</sup> HCV exhibits considerable genetic heterogeneity, with six major genotypes identified exhibiting important biological differences. See Chapter 13, *Knowledge of Viral Hepatitis Now*, paragraph 13.14.

in the study samples, the authors considered that their findings were ‘consistent with the majority of infections having been acquired by injecting drug use’.<sup>324</sup> In the discussion section the authors commented:

Most of the HCV infections in the population studied in this survey were probably acquired before 1986, mainly amongst people born between 1946 and 1970. The low prevalence in the more recent birth cohorts, implies that the incidence of HCV infection has declined. This epidemic is probably primarily associated with acquisition of HCV through injecting drug use. Seroprevalence studies both in the UK and Europe have found prevalence levels ranging from 50% to 90% in injecting drug users and the importance of drug use as a major risk factor for infection has been well documented. The use of recreational drugs in the UK increased steadily during the 1960’s and into the 1970’s. During this time, non-therapeutic heroin misuse emerged in London and spread to neighbouring counties. More widespread injecting of other illicit drugs, such as barbiturates, also increased during this period. The age profile of persons now presenting with HCV liver complications who have acquired HCV through injecting drug use reflects these historical patterns of injecting drug use.<sup>325</sup>

### **Other possible higher risk donors – the collection of blood from US military personnel in Scotland**

**26.204** The suggestion that the Inquiry should address the position of US military personnel as ‘higher risk’ donors was raised in correspondence from Messrs Thompsons, the solicitors acting for the patients, relatives and Haemophilia Society core participants, on 18 March 2011.<sup>326</sup>

**26.205** The Inquiry did not discover any research conducted in Scotland. As noted above (paragraph 26.66), an early English study (in 1972) found that there were no antigen or antibody positive results found – hence prevalence was 0% – on testing armed forces donors, including US Air Force personnel. Technology was not well developed at that time but the results offered some reassurance that there was no significant problem in this population.

**26.206** The Inquiry received evidence that blood was collected from US military personnel in Scotland at RAF Edzell between 1963 and 1996 and from the US naval base at Holy Loch from an unknown date until 1990.<sup>327</sup>

19.05.86	16
13.02.89	142
14.02.89	245
21.02.90	71
22.02.90	131

**26.209** Between 1982 and 1990, an approximate average of 600 donations a year was collected from US military personnel in Scotland. There were approximately 300,000 donations collected annually in Scotland during that period.<sup>328</sup> The donations collected from US military personnel in Scotland between 1982 and 1990 therefore represented approximately 0.2% of the total number of donations collected annually in Scotland.

**26.210** The Inquiry has also considered whether there was evidence to suggest that blood collected from US military personnel in Scotland carried a higher risk of transmission of NANB Hepatitis/Hepatitis C. Reference has been made to some data collected by the Transfusion Directors in the early 1970s. On a more general level, the Inquiry's attention was drawn to three papers in that regard that were suggested to have particular relevance.

**26.211** The first relevant source of information was a paper by Albert Sabin on the incidence of viral hepatitis among US military personnel published in 1976 in the *Yale Journal of Biology and Medicine*.<sup>329</sup> While the author concluded that the incidence of reported cases of icteric viral hepatitis (hepatitis, that is, associated with clinical observation of jaundice) was much higher in US military personnel than in comparable age groups in the civilian population, the author went on to state that the preliminary data strongly suggested that Hepatitis B (rather than Hepatitis A or the 'hypothetical' Hepatitis C) was the predominant viral cause of hepatitis among US military personnel throughout the world and that sexual promiscuity, rather than drug use, appeared to be a more likely explanation for that higher incidence.<sup>330</sup> The paper did not suggest or establish that US military personnel stationed in Scotland were likely to have a higher incidence of NANB Hepatitis than in the general population.

<sup>328</sup> SNBTS Blood Collection, 1975–1991 [PEN.010.0026] at 0029

<sup>329</sup> Sabin, 'Viral hepatitis: problems of incidence and control in military personnel', *Yale Journal of Biology and Medicine*, 1976; 49:259 [PEN.017.0944]

<sup>330</sup> *Ibid* [PEN.017.0944] at 0948–49

**26.212** Secondly, a paper by Kenneth Hyams and others on viral hepatitis in the US navy was published in the *American Journal of Epidemiology* in 1989.<sup>331</sup> The authors reported that, from 1974 to 1984: total first hospitalisations of US naval personnel for viral hepatitis declined, that there was a significant decrease in the incidence of confirmed cases of Hepatitis B and NANB Hepatitis and that the incidence of confirmed cases of Hepatitis A increased after 1980 when a commercial serologic test for acute Hepatitis A became available.<sup>332</sup> During each of the 10 study years, confirmed cases of Hepatitis B were the most frequent hepatitis diagnosis overall. Again, the study did not suggest or establish that US naval personnel stationed in Scotland were likely to have a higher incidence of NANB Hepatitis than the general Scottish population. Indeed, because the study was based on hospital admissions for cases of acute hepatitis and it is now known that most cases of Hepatitis C are non-icteric, the cases of viral hepatitis in the study are more likely to have been caused by Hepatitis A or Hepatitis B than by Hepatitis C.

**26.213** Finally, there was a short article by Michael D Parkinson and others on viral hepatitis in the US Air Force in the period 1980–89, published in the journal *Vaccine* in 1993.<sup>333</sup> It is apparent that no meaningful conclusions can be drawn from the very brief narration of the results of the study reported in the article. In any event, the article was published at a time when all blood collected by the SNBTS, including blood collected from US military personnel, was screened for HCV.

**26.214** In summary, the amount of blood collected from US military personnel in Scotland was minimal (about 0.2%) compared with the total amount of blood collected in Scotland. In addition, the Inquiry is unaware of any evidence to suggest that the SNBTS, the UK Government or any responsible Scottish agency knew or ought to have known during the 1970s or 1980s that blood collected from US military personnel in Scotland carried a higher risk of transmitting NANB Hepatitis, Hepatitis C or, indeed, HIV than blood collected from the general donor population.

## Discussion

### *Use of drugs*

**26.215** As indicated in the first part of this chapter, a current or recent history of injecting drugs, or physical evidence of having injected drugs, were seen throughout the reference period as grounds for deferment from donation for specified periods, or for exclusion from donation altogether. While the general policy may have been clear as it evolved from time to time, prior to 1983 the SNBTS did not provide uniform directions or recommendations for Regional Transfusion Directors and their staff to ensure, as best might be achieved, the application of that policy, for example, by asking prospective donors directly about drug use and/or including a question to that effect in the health check questionnaire.

**26.216** With the passage of time, oral evidence of practice in the 1970s and early 1980s is inherently unreliable, especially in the case of Regional Transfusion Directors and more senior officers of the SNBTS who would not, in the general run of things, be involved regularly in routine donor session work. However, the evidence on this matter does tend to suggest that direct questioning of the donor on their drug use may not then have been

<sup>331</sup> Hyams et al, 'Viral hepatitis in the US navy, 1975–1984', *American Journal of Epidemiology*, 1989; 130:319 [PEN.017.0952]

<sup>332</sup> Ibid [PEN.017.0952] at 0953–54. The authors recognised, however, that 'the decline in reported cases of [NANB] hepatitis, which was most pronounced after a test for acute hepatitis A became available, was probably due in part to more accurate diagnosis of hepatitis A'. At 0958.

<sup>333</sup> Parkinson et al, 'Viral hepatitis in the US Air Force, 1989–1989', *Vaccine*, 1993; 11(5):516 [PEN.019.0861]

routinely used as a means of enforcing that policy. That evidence is limited. Mrs Prior ceased working as a MTA in the west of Scotland in 1974. Dr Mitchell thought that there was no questioning on injecting drugs in the 1970s but thought that it might have come in later in the consideration of AIDS. Dr McClelland was only confident that the majority of the staff would have questioned donors about drug use from the early 1980s onwards.

**26.217** Observation by donor session staff, short of a thorough and structured examination backed up by relevant and detailed questioning, might not have uncovered the full extent of intravenous drug use among prospective donors. The 1971 WHO Guide seems to have been excessively optimistic in suggesting that medical officers should be able to pick out 'drug addicts' in distinguishing acceptable from unacceptable donors. However, it may have envisaged a more thorough medical examination than typically happened in Scotland in the 1970s.

**26.218** In any event, injection of controlled drugs by a donor might have ceased long before the examination and have left no surviving traces either on the donor's body or in their behaviour. As was to become clear after tests for Hepatitis C became available, infection could remain asymptomatic, but transmissible, for decades in individuals who had ceased to be IVDUs and who may never have been addicted to intravenous drugs. The true nature of the risk was not known in the 1970s and early 1980s.

**26.219** The principal guidance available to the Regional Directors of the SNBTS prior to 1983 appears to have been the 1977 *Memorandum on the Selection, Medical Examination and Care of Blood Donors*. Until the arrival of AIDS, neither international nor UK produced guidance seems to have contained any explicit advice emphasising the need to question blood donors about their drug usage, in particular, any intravenous drug usage. In June 1983, the South East BTS introduced donor questions about risk factors including intravenous drug use and by early 1984, at the latest, this had become SNBTS practice. Professor Juhani Leikola of the Finnish Red Cross Blood Transfusion Service confirmed that the donor questionnaires used in Finland in the late 1970s/early 1980s did not include a question as to whether the donor had ever injected or used drugs. He also indicated that it was not until 1983 when 'AIDS came into the picture' that questioning of donors about intravenous drug use started in Finland. The numbers of those who were drug dependent within prison and other penal institutions remained relatively stable until the early 1980s. The upward trend in drug use outside such institutions was modest until 1980. In and after 1981 the rate of growth in drug abuse accelerated.<sup>334</sup> This may also assist in explaining the relative lack of emphasis on the questioning of donors up until the early 1980s. A number of the Regional Directors were concerned about the sensitivities of the donor population and this was, plainly, a legitimate consideration given that the blood supply depended upon voluntary donation. In both Finland and Scotland AIDS seems to have been the catalyst for the introduction of the routine questioning of donors about the injecting of drugs.

### *Prisons and other penal establishments*

**26.220** By the mid-1970s there was some international guidance tending towards advice that blood should not be collected for transfusion from those detained in penal institutions. It was emphasised, however, that decisions on the designation of high risk groups was

---

<sup>334</sup> See the data appended to the Schnier, Goldberg paper on the Estimated Number of individuals Infected and Alive in 2011 as a Consequence of Blood Transfusion in Scotland 1970–1991: [PEN.019.0899] at 0902.

a matter for local decision in the light of circumstances obtaining from time to time and having regard to the need for and availability of blood. As noted at the beginning of this chapter, international practice varied widely in respect of collecting blood from penal institutions. National circumstances clearly varied considerably. The policy and practice in Scotland must be considered in the light of local circumstances here.

### ***Responsibility for policy***

**26.221** When, at a meeting on 26 September 1973, the incidence of Australian antigen in prison donors was reported to be higher than in the general public, the English and Welsh Regional Transfusion Directors agreed that, if it were decided to discontinue accepting blood donations from prisoners, the Home Office should be informed before any local action was taken.<sup>335</sup> There is, however, no evidence that there was a similar concern within the Scottish administration at the time. As discussed in Chapter 17, *Blood and Blood Products Management*, policy was a matter for ministers and their civil service advisers.

**26.222** The letter dated 1 May 1975 by Dr Yellowlees, referred to earlier, was a clear example of government giving advice on donor selection, at least in England and Wales. Equally, Dr Wallace's comments in his 1977 publication, that it was socially and psychologically undesirable to exclude prisoners from the donor population, acknowledged that the collection of blood required to be seen not only in the context of the adequacy and safety of the blood supply. He referred to the role of blood donation in prisoner rehabilitation, observing that some prison donors became regular volunteers after their release. The DHSS document, published in 1979 and applicable throughout the UK, *Standards for the Collection and processing of Blood and Blood Components and the Manufacture of Associated Sterile Fluids*, also provided government advice on this matter. Dr Brookes' experience in London before moving to Dundee in 1981 had informed her that it was long-standing UK Government policy that the BTS should visit prisons to permit prisoners to make some restitution to society and to do something, which many in the community did, to help their return to normal life after release. Dr McClelland's evidence that the Director of HMP Saughton made several representations to the Edinburgh and South East of Scotland BTS to return to the prison and resume sessions after Dr McClelland had terminated the practice in 1981, indicated in a practical way that the rationale for the practice included policy relating to prison management rather than exclusively to SNBTS management.

**26.223** The wider policy aspects of the question were clearly recognised by the UK government. The minute sent by Mr JB Brown, Medicines Division, to his DHSS colleagues on 27 July 1983 on the use of blood from prisons, sought departmental guidance on the issue at the request of the Medicines Division's Inspection Action Group.<sup>336</sup> Mr Winstanley commented on the need to consult the Home Office in view of the importance placed on the social responsibility aspect of prison sessions. The SHHD manuscript file note dated 11 August 1983 recorded the outcome of Mr Winstanley's contact with the SHHD in respect of the Medicines Inspectorate's query.<sup>337</sup> It recorded that the situation in Scotland would be kept under review, 'particularly to hear of developments in England which might be influenced by Home Office views'.

---

<sup>335</sup> Minutes of Meeting [DHF.002.7960] at 7967

<sup>336</sup> Minute [SGH.001.0575]

<sup>337</sup> File Note [SGH.001.0571]

**26.224** By the date of his minute of 23 August 1983, quoted in paragraph 26.128, Mr Winstanley had clearly identified the problem presented by the risk of transmission of AIDS. His view reflected the position common at the time, that it was difficult to advise on Departmental policy on the collection of blood from borstals and prisons since it was for individual Regional Transfusion Directors to determine how and from where donations were sought. However, his observation on the need to liaise closely with the Home Office underlined the wider policy issue. The Home Office had in the past been in favour of blood donation by prisoners as an aspect of policy unrelated to the risk of transmitting disease. It was clearly understood at the meeting of SNBTS Directors on 13 September 1983 that the DHSS would wish to consult the Home Office on account of that department's previous wish to encourage donation in prisons.<sup>338</sup>

**26.225** The letter dated 1 May 1975 by Dr Yellowlees referred to earlier was a clear example of government giving advice on donor selection, at least in England and Wales, as was the document published by the DHSS in 1979 and applicable throughout the UK, on the *Standards for the Collection and Processing of Blood and Blood Components and the Manufacture of Associated Sterile Fluids*. The intervention of the Medicines Inspectorate in 1982 clearly had an impact on the thinking of the Working Party on the Selection of Donors. Among other considerations, it undermined further the notion within the SHHD that the selection of donors was wholly a matter for transfusion directors.

**26.226** It is implicit that there will be issues affecting the portfolios of more than one government Minister or, in the case of Scotland before devolution, more than one department of the Scottish Office. Resolution of any differences of substance was ultimately a matter for political office holders rather than officials. The exchanges between UK departments were appropriate. However it was arrived at, the decision communicated by Dr Yellowlees in May 1975 removed from the NBTS direct responsibility for continued prison collections, notwithstanding the relatively high risk of transmitting Hepatitis B.

**26.227** Dr Wallace's view was not a policy consideration for the SNBTS. The social factors that entered into the debate – whether it was socially or psychologically desirable to exclude prisoners, whether blood donation assisted rehabilitation and similar formulations – were issues for government. In deciding on social policy, it was for ministers to determine whether the incidental benefits to prisoners of giving blood should prevail over risks to the safety of recipients of the blood. That would have required advice on whether there was a risk and, if so, on its magnitude. Social cost and benefit might not have been easy to balance, though the safety and well-being of NHS patients would on any view have been a high priority. It was clearly, however, not a matter for a transfusion specialist such as Dr Wallace to decide. The emphasis in the documents on the views of the DHSS was a reflection of the political reality: collection in prisons was not exclusively a matter appropriately devolved to technical specialists. It engaged wider social values and was properly a matter for ministers and government policy.

**26.228** If that was recognised at UK level, it was appropriate that it should be recognised at local level in Scotland. As set out in Chapter 17, *Blood and Blood Products Management*, paragraph 17.20, it was the statutory duty of the Secretary of State for Scotland, and now the Scottish Ministers, to provide effective health care in Scotland, including promoting the effective provision of blood transfusion services, and the Scottish Ministers have

---

<sup>338</sup> Minutes of Meeting [SNF.001.0072] at 0077

operational control of health care policy. The CSA had delegated responsibility for the operational management of blood services but was subject to, and obliged to act in accordance with, such directions as might be given by the Secretary of State. Devolving management responsibility to the CSA could not remove ultimate responsibility from ministers for wider social policy.

**26.229** The evidence of Dr Scott, Dr McIntyre and Mr Wastle, that it was for SNBTS Transfusion Directors to deal with the issue, to the extent that they did not know whether the SHHD had ever considered it, was clearly a true reflection of officials' attitude at the time and is accepted as a reliable account of their own views and practices. While there is evidence that the Home Office in England and Wales encouraged donations in prisons, there was no evidence before the Inquiry that the SHHD encouraged donation in prisons in Scotland. Instead, the SHHD took a passive role, noting without demur Dr Yellowlees' letter dated 1 May 1975 and otherwise leaving it for the SNBTS to decide whether prison collection was appropriate.

**26.230** The Regional Transfusion Directors were an appropriate group to advise government on the medical and technical aspects of this question. Individually they may have held different views on the answer from time to time but the Inquiry heard no evidence that would have cast doubt on their competence to assess risk according to the standards of the time and to contribute to the debate. It was not, however, the appropriate group to advise on, much less to determine, the social issues raised. On the other hand, there was no evidence before the Inquiry that the SNBTS Directors advised the SHHD of any concerns regarding collection from prisons.

*When and how was the issue raised?*

**26.231** It is appropriate for the Inquiry to discuss the questions that arise in relation to timing and the presentation of the issue of prison donations with reference to relevant medical and technical aspects.

**26.232** Regional Transfusion Directors were free to follow their own practices. Dr McClelland's decision in 1981 to discontinue prison sessions was prompted by the views of the regional donor organiser.<sup>339</sup> Her reasons – related to the threatening prison environment, the difficulty of obtaining clear, transparent answers and other social factors – would have been of similar weight in any region. Dr McClelland responded to her views without reference to other Regional Transfusion Directors, a clear example of the exercise of the local autonomy that characterised the service at the time. Similarly, Dr McClelland received, but did not respond positively to, representations by the Director of HMP Saughton to return and run further sessions. It would not be appropriate to draw general conclusions relating to other regions from the timing or circumstances of his decisions. They were not prompted by apprehensions relating to transmission of infection and they were not supported by any well-formulated policy.

**26.233** Dr Brookes was opposed to prison collections before she came to Scotland and clearly articulated her concerns after she arrived in Dundee in 1981. After she took up her post, she vetoed a proposal for additional prison sessions. The last prison session in her region was 2 August 1983. She deliberately raised her concerns with the Medicines Inspectors and was well informed of the practice of her Welsh and English colleagues. After

---

<sup>339</sup> Day 9, page 79

the meeting on 29 March 1983 Dr Brookes asked the organising secretary in Dundee to phase out prison and young offenders' sessions over the coming year, accommodating the Centre's programme of donor sessions which was generally confirmed one year ahead.<sup>340</sup>

**26.234** It is clear from Dr Brookes' evidence that it was at the meeting on 29 March 1983 that it became evident to her that, although the Directors were divided, individual Directors who wished to discontinue prison sessions could do so. At that same meeting Professor Urbaniak had indicated that he intended to review the situation in his region and, like Dr Brookes, he concluded that the practice was undesirable and terminated it. It seems reasonable to conclude that for the Scottish regions as a whole, excluding Edinburgh and the South East, the issue became live in March 1983. By then, the Directors were, effectively, solely responsible for implementing their individual decisions and discontinuing or not according to their individual assessments of the needs of their regions.

**26.235** As in other areas, Professor Leikola's insight into the position up to that point was helpful. There had been a long standing practice of collecting blood in prisons. He said:

[T]he impression that I have received from reading these different documents that you sent me is that this matter was really not taken into serious consideration during the late 1970s up until 1981 and of course then 1983.

So my impression – and this is just my impression from reading these documents – is that this tradition went on without really being seriously considered whether it should now be stopped because of various facts that had been published during the 1970s.<sup>341</sup>

**26.236** Once the equilibrium in a static society is disturbed, the potential for change may be unlimited. Disturbing the established position is not necessarily easy, however. Dr McClelland's observation was pertinent. Again, as noted above, he spoke of:

[T]he problem where you have within a community, a professional communal, a sort of very powerful sort of dome of received opinion, which is sitting over everybody and they have a belief system that this isn't a problem. And therefore even when perhaps some individuals sort of stand up and make a noise and say, "I think there is a problem" ... actually they seem to be a nuisance because they get in the way of what we are doing at the moment, and that's really a sort of sociological problem, I'm sure not unique to blood services and it is actually very difficult to deal with.<sup>342</sup>

**26.237** The difficulty of challenging the status quo of entrenched opinion perhaps explains most cases of prolonged practices after they are or should be challenged. One can exclude conspiracy: there was no decision to continue to accept donations in the face of contrary indications. The practice simply continued until it stopped.

***Should the practice have been discontinued earlier than it was?***

**26.238** On the evidence there is an obvious question whether prison collections were at all necessary in the reference period to secure the blood supply. The issue relates to demand for blood components and in particular for red cells. Packed red cells were produced in

---

<sup>340</sup> Dr Brookes' Witness Statement [WIT.003.0057] at 0061–62

<sup>341</sup> Day 13, pages 80–81

<sup>342</sup> Day 9, pages 131–134

the course of preparation of plasma for fractionation at PFC and surplus production was sent to England. The preference in the west of Scotland appears to have been for blood components produced locally (mainly at Law Hospital) and that provides the principal context for discussion.

**26.239** Prison collection was not necessary in Edinburgh and south east Scotland: discontinuation of the practice caused no supply problems. The dedication of a high proportion of whole blood collections to the preparation of plasma for supply to PFC ensured an ample supply of red cells for surgical and other medical applications. Apart from some very general observations that there were occasional shortages during local holidays and other periods for example, the only region that consistently sought to justify prison collections on supply grounds was the west of Scotland.

**26.240** It has to be accepted that there were occasional issues over supply in the west of Scotland but it cannot be accepted that those problems were necessary (or, at least, insurmountable). Professor Cash's observation on this issue is pertinent: it would have required a little less autonomy and a little more cross-regional support when times got difficult. Given the total input of red cells in the whole of Scotland, the loss of prison donations could easily have been coped with.<sup>343</sup> The continued practice cannot, on the evidence, be justified on the grounds that without prison donations there would have been shortages of red cells for surgical or other medical applications that could not be made good from Scottish sources. Dr Mitchell's comment that he preferred to cope from within his own region<sup>344</sup> was at odds with the need for more collaborative working.

**26.241** The impact of the AIDS epidemic finally led to a change of mind in Glasgow and the west of Scotland.<sup>345</sup> The risk of transmission of HIV 'tipped the balance' as far as Glasgow was concerned. Implicitly, the risk of transmission of Hepatitis B and NANB Hepatitis had not tipped the balance and collections did not cease until 25 March 1984, about the time of Dr Gallo's publication of the discovery of HTLV-III. (See Chapter 11, *HIV/AIDS Aetiology*.)

**26.242** There was ample evidence before March 1984 that Hepatitis B and NANB Hepatitis presented threats to recipients of blood, blood components and blood products. In the case of Hepatitis B, there was ample evidence that there was a relatively high prevalence of infection in the prison population. The paper by Dr Wallace and colleagues published in March 1972 represented a major advance in the collection and analysis of relevant data: overall, the incidence of Hepatitis B positive donations among prison donors (0.65%) was just under seven times higher than that in the general public (0.10%). The English and Welsh Directors' researches yielded similar data when they completed their exercise in July 1974: in 1973 the incidence of Hepatitis B antigen in new general public and factory donors was 0.09% whereas the incidence of Hepatitis B antigen in donors in prisons, borstals and similar institutions in 1973 and Jan-March 1974 was 0.43%.<sup>346</sup> The validity of the data did not depend on whether prisoners were drug addicts or how they came to be infected. The numbers defined the relative seriousness of the problem prison donors presented. The Dow/Follett report of July 1984 showed that raised ALT in the prison population was ten times the incidence found in the general population.

<sup>346</sup> Frequency of HBAg and Anti-HBAg Exported by RTCs New General Public and Frequency Donors and in Donors in Armed Forces and in Prison Borstals and Similar Institutions [SGH.001.7095]

**26.243** In earlier chapters of this Report, the Inquiry has discussed:

- The effectiveness of basic collection procedures to identify the risks presented by potential donors. The discussion showed that the procedures were not effective in the case of a person unwilling or unable to provide information on the risks arising from his or her medical history, such as a history of hepatitis/jaundice or blood transfusion. They were equally ineffective in the case of a person with a past or current history of injecting drug use who was unwilling to disclose that practice and who either did not have signs of current drug use or had taken pains to conceal track marks from investigators.
- The effectiveness of screening technology to identify blood that presented risk of transmission of infection. HBsAg screening was very ineffective until the mid-1970s in identifying blood infected with Hepatitis B. It was totally ineffective in identifying blood infected with NANB Hepatitis.

**26.244** If it is known that there is a real risk of transmitting serious infection; that identification of that risk as presented by donors is beset by procedural and technological problems; and that a particular group presents risk of transmitting infection of an order of magnitude greater than the general population, there appears at first blush to be good reason to avoid that population.

**26.245** The position is complicated by a number of factors, however. HBsAg assays were initially very ineffective: a detection rate of 25–30% would have suggested that a population with a relatively high prevalence of infection should have been avoided. The tests became more efficient with time, however, and that factor became less significant.

**26.246** The issue was thought to have diminished by the mid-1970s. Dr Yellowlees' letter of 1 May 1975 shows the official UK response to the perception of risk at that stage, when confidence in screening for HBsAg was at its peak.

**26.247** There were, however, good scientific and medical grounds for terminating prison collections by the early 1980s. The time frame for consideration of the issue is defined roughly by these dates. By the early 1980s concerns about prison collections were being articulated by Directors such as Dr Brookes and they were probably shared by Professor Cash and others. Dr McClelland acted alone in not collecting blood from prisons in his region after December 1981: others might have taken a similar step. There was still no consensus even in 1983. The role of a specialist service such as the SNBTS was to express a view that might have persuaded government to act. While the SNBTS could not alter UK Government policies understood to be in place that were opposed to termination on social or rehabilitation grounds, it would have been reasonable for the SNBTS to have formulated a collective view for communication to the SHHD on whether there were medical and scientific reasons to suggest that the continuation of the practice presented an unnecessary risk to patients. In the absence of the SNBTS bringing the potential health risks of collecting blood from prisons to the attention of the SHHD, one can perhaps understand why SHHD officials did not consider the issue or bring it to the attention of ministers. By way of example, the Finnish Red Cross had considered the matter and had taken the decision, in 1975, to cease collection in penal institutions having regard to the results from the introduction of more sensitive Hepatitis B screening tests around that time. The SNBTS Transfusion Directors could have given similar advice to the SHHD as Dr Helske gave to his government agencies, although it must be borne in mind that

Finland had a highly centralised service. It appears that it was not exposed to differences of opinion such as existed between Dr Wallace and Dr Brookes.

**26.248** Although by March 1983 Professor Cash, the National Medical Director, appears to have been of the view that the practice of collecting blood in prisons should cease, he could not bring about the end of that practice in Scotland. Regional Directors did not report to, or accept review by, the National Director. If a Regional Director considered that the practice should continue in his region, he was free to follow that course. One of the effects of this limitation in the effective powers of the National Medical Director of the SNBTS was that, in the absence of consensus amongst the Regional Directors, collective action could not be taken.

**26.249** Even if the Scottish Transfusion Directors had tried to reach a collective view before 1983 on the practice of continued collection in penal institutions, it is not obvious that agreement would have been reached given the differences of professional opinion among them. It is important to avoid colouring the evidence that has been gathered, with the benefit of hindsight. A speculative proposition about ‘what should have been obvious’ would be easily made and might be superficially attractive; there is, however, no basis on which it could be suggested that the differences of opinion among experts were other than genuinely held and honestly and reliably reported. Given the evidence that has been narrated, including the lack of a uniform practice among the transfusion regions in England and Wales or in other European countries, there is no point in the chronology at which it can be said that the SNBTS Directors should have delivered a consensus opinion to government that prison collections should be terminated before 1983 when they voluntarily began to withdraw from prison collections (with the exception of Dr McClelland who, prompted by his regional donor organiser, had stopped earlier).

## Conclusions

### *Intravenous drug use*

**26.250** The International Society of Blood Transfusion (ISBT) Guide *Criteria for the selection of blood donors* of 1976 identified individuals suspected to be parenteral drug addicts among those who should be excluded from donating blood.

**26.251** In 1977 the BTS produced the *Memorandum on the Selection, Medical Examination and Care of Blood Donors*. It was used as guidance by all Scottish RTCs in developing their local policies. It stated that ‘Illicit drug taking if admitted or suspected should debar’. Similar wording was contained in the *Standards for the Collection and Processing of Blood and Blood Components etc* published by the DHSS in 1979.

**26.252** Before the advent of AIDS in the early 1980s, therefore, it was known that drug taking by a potential donor and, in particular, intravenous drug taking, should exclude the potential donor from donating blood. The measures implemented within the SNBTS in order to exclude such individuals from donating blood included inspection, assessment and, to a limited extent, interview. However, up until the advent of AIDS in the early 1980s it seems likely that there was no uniform policy within the organisation in order to ensure that donors were routinely and directly questioned on their drug use.

**26.253** In any voluntary donation system there would always have been (and there continue to be) limitations on the procedures that might reasonably be followed to exclude the risk of accepting blood from a prospective donor with a history of intravenous drug

use. Full medical examination was, and remains, impractical. The health questionnaire forms used in current practice contain questions focused on risk associated with ‘ever’ having injected drugs and the forms must be signed by prospective donors in the presence of a member of staff. The requirement for signature was an important step forward. However, the effectiveness of the collection system to exclude or reduce risk related to parenteral drug use (in particular, in relation to risks arising from blood-borne viruses for which sensitive screening tests are not yet available) still depends on the reliability of the prospective donor and, at the end of the day, in some cases at least, on the donor’s honesty. Notwithstanding the risk of upsetting some prospective donors, there is no alternative to emphasising in direct interview the prohibition on donation associated with a history of injecting drugs, so as to limit the scope for error or the provision of inaccurate information.

### *Collection of blood from prisons*

**26.254** The evidence obtained by the Inquiry indicates that blood was collected from penal institutions in Scotland from at least 1957 until the last prison session took place in each individual region.<sup>347</sup> The last prison donor sessions took place respectively in the south east (Edinburgh) on 22 December 1981; north (Inverness) on 24 February 1983; north east (Aberdeen) on 28 July 1983; east (Dundee) on 2 August 1983; and west (Glasgow) on 25 March 1984.<sup>348</sup>

**26.255** The ISBT *Criteria for the Selection of Blood Donors* in 1976 proposed that prospective donors should be excluded if they are ‘inmates of a correctional institution’. However, in this as in other matters, individual Transfusion Directors exercised a high degree of autonomy in donor selection and it is not possible to state that there was uniform practice.

**26.256** Practice among European blood transfusion services in respect of collecting blood from prisoners clearly differed. In particular:

- Some countries never collected blood from prisoners (Denmark, the Netherlands<sup>349</sup> and Eire).
- In the 1970s some countries introduced a permanent or temporary deferral of blood collected from prisoners (Switzerland, 1970<sup>350</sup>; Belgium, mid-1970s; Finland 1975).
- Some countries ceased the collection of blood from prisons in the 1980s (England and Northern Ireland, 1983; Scotland, 1984; Luxembourg, 1985; France, 1985–89).<sup>351</sup>
- Other countries did not introduce a permanent or temporary deferral of blood donation by prisoners until the 1990s (Portugal, 1990; Austria, 1995; Germany, 1996; Norway, 1997).<sup>352</sup>

<sup>347</sup> The commencement of the practice of prison collection in 1957 is taken from the SNBTS paper, ‘Collection of Blood in Prisons’ [PEN.018.1521] at 1525.

<sup>348</sup> SNBTS Blood Collection 1975–1991 [PEN.010.0003] at 0012. The prisons visited by each RTC are listed in SNBTS Blood Collection 1975–1991 – further response [PEN.010.0026] at 0028

<sup>349</sup> It was also Professor Leikola’s understanding, based on discussion with Professor van Aken of the Netherlands Red Cross Blood Transfusion Service, that the Netherlands never collected blood in prisons: Day 13, pages 58–59

<sup>350</sup> See also the evidence of Professor Leikola: Day 13, pages 59–62

<sup>351</sup> Ibid pages 62–64

<sup>352</sup> See also the discussion in the SNBTS paper ‘Collection of Blood in Prisons’ [PEN.018.1521] at 1529

**26.257** There was no evidence before the Inquiry that any additional steps were taken at prison donor sessions in Scotland to seek to screen out higher risk donors such as those who had ever injected drugs.

**26.258** Dr McClelland's decision in 1981 to discontinue prison sessions was prompted by the views of the regional donor organiser. The decision was based more on the fact that prisons were felt to be an unsuitable environment in which to conduct donor sessions, than on concerns that prisoners' blood was thought to carry an increased risk of infectious diseases, including NANB Hepatitis. It was open to other Regional Transfusion Directors to have done the same.

**26.259** It appears that Regional Transfusion Directors in Scotland collectively did not apply their minds to whether collection from penal institutions carried a greater risk of transmission of infectious disease and whether, therefore, the practice should continue until the matter was raised by the Medicines Inspectorate in 1982. However, the Medicines Inspectorate appear to have raised the matter at that juncture because Dr Brookes had informed them of her concerns about the practice of prison collection when they inspected Dundee in March 1982. The matter was first discussed by the Scottish Transfusion Directors, collectively, at their meeting on 29 March 1983.

**26.260** It is unfortunate that consideration was not given by the Scottish Transfusion Directors, collectively, as to the appropriateness of continuing with prison collection prior to the matter being raised by the Medicines Inspectorate in 1982. There was evidence in the 1970s showing an increased prevalence of Hepatitis B in the prison population, knowledge that tests for Hepatitis B were not completely sensitive and emerging knowledge of an additional hepatitis disease, NANB Hepatitis, from about 1974 onwards which, like Hepatitis B, was also transmitted by blood.

**26.261** Had the Transfusion Directors applied their minds to the practice, however, it cannot be said that they are likely to have decided to stop collecting in prisons or that it was unreasonable for the practice to have continued until the early 1980s. In particular:

- While there was evidence in the 1970s of an increased prevalence of Hepatitis B among the prison population in Scotland, it was reasonable to think that by the mid-1970s available tests for Hepatitis B had become sufficiently sensitive to detect most, if not all, carriers of that virus.
- While knowledge of NANB Hepatitis emerged and developed from around 1974 onwards, the disease was considered in the late 1970s and early 1980s to be clinically mild in most cases.
- It does not seem to have been suggested in the late 1970s and early 1980s that there may have been an increased prevalence of NANB Hepatitis in the prison population in Scotland (and had such a suggestion been made it could only have been a tentative one given the absence of any tests for NANB Hepatitis with which to establish the hypothesis).

**26.262** Against that background, and in the absence of any instruction or direction from government in Scotland, it cannot be said that the Scottish Regional Transfusion Directors acted unreasonably in continuing to collect blood from prisons until the early 1980s.

**26.263** In addition, given the variation in practice in transfusion regions in England and Wales and in other European countries, it cannot be said that the practice in Scotland in the 1970s and early 1980s to collect blood from penal institutions was out of step with generally accepted practice elsewhere.

**26.264** With the benefit of hindsight, it seems likely that there was a higher prevalence of Hepatitis C in the prison population in Scotland in the 1970s and early 1980s than among the general donor population, probably as a result of a higher proportion of prisoners with a history of injecting drug use. It is not possible so long after the event and given, in particular, the lack of data on the incidence of NANB Hepatitis/Hepatitis C among prisoners in Scotland in the 1970s and early 1980s (and indeed the lack of data on the incidence of NANBH/Hepatitis C in the general population and general donor population at that time) to estimate the extent to which blood collected from penal institutions carried an increased risk of transmitting HCV. All that can be concluded, with the benefit of hindsight, is that blood collected from prisoners during that period is likely to have had an increased risk of transmitting HCV, albeit the chance of receiving blood collected from prisoners was, overall, relatively low given that only approximately 1% of all donations collected in Scotland between 1975 and 1984 was collected from penal institutions.

#### *US Military Personnel*

**26.265** The amount of blood collected by the SNBTS from US military personnel based in Scotland was even smaller, ie approximately 0.2% of all donations collected in Scotland. In any event, there is no support in the evidence before the Inquiry for the suggestion that American service personnel presented a higher risk of transmitting HCV (or indeed HIV) than the general Scottish or UK donor population.

## Appendix to Chapter 26

Table 26.1: Blood donation and prisoners, Synopsis of the answers by EBA members, September 2004

	Mandatory deferral	Reason for deferral	Mode of deferral	Time of introduction	The measure challenged?	Ethical issues
Austria	Yes	Epidemiological HBV, HCV	Permanently?	~1995	Never	Not voluntary
Belgium	Yes	Epidemiological HBV	One year	Mid 1970s	Never	None
Denmark	Yes	Epidemiological	One year	Never been used as blood donors	Never	None
England	Yes	Epidemiological HBV, IV drug abuse		1980s	Never	None
Finland	Yes	Epidemiological HBV		1975	Prisoners' organisation	None
France	Yes	Epidemiological HBV, HIV	Not permanently	1985/1989	Prison administration	Rehabilitation of prisoners
Germany	Yes	Epidemiological	Permanently	1996	Prison administration	None Rehabilitation?
Ireland	Yes	Epidemiological HBV, HCV	One year after release	Never		None
Luxembourg	Yes	Epidemiological HIV		1985	Never	None
Netherlands	No	Evaluation of individual risk behaviour		Early 1980s. No blood collection in prisons	Never	True volunteer status
Northern Ireland	Yes	"high risk"		1983	Prisoners' representatives	"True volunteers?"
Norway	Yes	Epidemiological	One year after a 72-hour arrest	1997	Never	None
Portugal	Yes	Epidemiological		1990	No	None
Scotland	Yes	Epidemiological		1983		None
Sweden	No		Risk evaluation of the individual. Deferral of 6 months after 72 hours in prison			
Switzerland	Yes	Epidemiological HBV; drug abuse	Only persons in prison	1970	Never	None
Wales	not deferred		Those serving a custodial sentence cannot donate			

**Table 26.2: Donations collected in each Scottish RTC 1971–84**

Year	Total number of donations in each region					Total Scottish donations	Total prison donations*	Prison donations (% Total)
	Edinburgh	Aberdeen	Inverness	Glasgow	Dundee			
1971	n/a	n/a	8500	107,251	24,654	n/a	1126	n/a
1972	n/a	21,156	9000	107,462	25,258	n/a	902	n/a

## CHAPTER 27

### SURROGATE TESTING OF DONATED BLOOD FOR NON-A, NON-B HEPATITIS

**27.1** This chapter deals with the topic of surrogate testing of blood donors for non-A, non-B Hepatitis (NANB Hepatitis) in the late 1980s. The chapter is divided into four parts: (i) an introduction to the topic, (ii) detailed narrative of events in the USA, Europe and the UK, (iii) discussion of the main issues that arise and (iv) the conclusions reached by the Inquiry.

#### Introduction

**27.2** As indicated at the end of the last chapter, in the second half of the 1970s and early 1980s the existence of non-A, non-B viral hepatitis was first postulated and then established.<sup>1</sup> There was, however, no serological or other test available for screening donated blood for markers of infection. In the USA a debate emerged as to whether to introduce tests for 'surrogate' (or 'indirect') markers of NANB Hepatitis infection and a programme of surrogate testing was eventually introduced there. Surrogate testing, described below, was not adopted in the UK generally or in Scotland in particular and the reasons for that became one of the issues for discussion at the Inquiry's public hearings of evidence. This chapter incorporates the Inquiry's discussion and findings related to that topic.

**27.3** As more fully discussed elsewhere in this Report, the Hepatitis B virus (HBV) was identified in 1963,<sup>2</sup> and screening of blood donors in Scotland for the Hepatitis B surface antigen (HBsAg) was introduced in the early 1970s. The Hepatitis A virus (HAV) was identified in 1973<sup>3</sup> but was not associated with the transmission of hepatitis by transfusion. In 1974, however, a US study reported that an agent that was neither HAV nor HBV seemed to be responsible for a substantial proportion of cases of post-transfusion hepatitis.<sup>4</sup> The term non-A, non-B Hepatitis came to be used for cases of hepatitis in which Hepatitis A and Hepatitis B were excluded.<sup>5</sup>

#### *Surrogate testing: ALT and anti-HBc as indirect markers of possible infection*

**27.4** Despite work by many researchers in the late 1970s and early 1980s, the virus responsible for most cases of NANB Hepatitis, the Hepatitis C virus (HCV), was not identified until 1988.<sup>6</sup> In the meantime, research groups in the USA reported a correlation between elevated alanine aminotransferase (ALT)<sup>7</sup> levels in donors and an increased risk of transfusion recipients developing NANB Hepatitis.<sup>8</sup> The same research groups later reported

<sup>1</sup> See also Chapters 13–16 generally.

<sup>2</sup> Blumberg et al, 'A serum antigen (Australia antigen) in Down's Syndrome, Leukemia and Hepatitis', *Annals of internal Medicine*, 1967; 66:924 [PEN.002.0792]. See Chapter 14, *Knowledge of Viral Hepatitis 1*, paragraph 14.1.

<sup>3</sup> Feinstone et al, 'Hepatitis A: detection by immune electron microscopy of a virus like antigen associated with acute illness', *Science*, 1973; 182:1026 [PEN.010.0110]. See Chapter 14, *Knowledge of Viral Hepatitis 1*, paragraph 14.63.

<sup>4</sup> Prince et al, 'Long-incubation post-transfusion hepatitis without serological evidence of exposure to hepatitis B virus', *The Lancet*, 1974:241 [LIT.001.0363]. See Chapter 14 *Knowledge of Viral Hepatitis 1*, paragraph 14.64.

<sup>5</sup> Typically, the term NANB Hepatitis also depended upon the exclusion of diseases such as Cytomegalovirus (CMV) and Epstein-Barr Virus (EBV), both of which are known to cause hepatic disorder.

<sup>6</sup> A 1986 paper, for example, stated: 'There are more than 40 published reports of specific NANB hepatitis assays, many of which have been reviewed. Not a single test, however, has been reproducibly and independently confirmed, not a single test has successfully distinguished proved NANB hepatitis infectious sera from control sera when tested under independent code, and not a single test has moved from the research laboratory to the point of practical application.' Dienstag and Alter, '[NANB] Hepatitis: Evolving Epidemiologic and Clinical Perspective', *Seminars in Liver Disease*, 1986; 6:67 [LIT.001.1675] at 1682

<sup>7</sup> This protein, synthesised in liver cells and normally present in low levels in the blood, becomes elevated when the liver is disordered by virus infection or other hepatic disorders.

<sup>8</sup> Aach et al, 'Serum [ALT] of donors in relation to the risk of [NANB] hepatitis in recipients: the TTV study', *New England Journal of Medicine*, 1981; 304:889 [LIT.001.0753] (the TTV study, discussed below) and Alter et al, 'Donor transaminase and recipient hepatitis', *Journal of the American Medical Association*, 1981; 246:630 [LIT.001.1817] (the NIH study, discussed below).

an association between the presence of antibody to Hepatitis B core antigen (anti-HBc) in donors and an increased risk of NANB Hepatitis in recipients.<sup>9</sup> It was therefore suggested that elevated ALT and/or anti-HBc might be useful 'surrogate markers' for NANB Hepatitis. A surrogate marker is a directly measurable physical entity (usually measured in a blood test) that correlates (has a statistical association) with a disease, where it is not possible to test directly for the disease or where any direct test would be problematic.

**27.5** There were, however, difficulties with the use of either raised ALT or the presence of anti-HBc as surrogate markers for NANB Hepatitis.

**27.6** The underlying difficulty with the use of surrogate tests to identify donors with NANB Hepatitis was twofold. First, such tests were by their very nature non-specific<sup>10</sup> – there would be many 'false positives' where the test result for the surrogate marker (ALT or anti-HBc) was positive but the NANB Hepatitis virus (HCV) was not in fact present. Secondly, such tests also lacked sensitivity<sup>11</sup> – there would be many 'false negatives' where the virus was in fact present, but was not detected because the test was not sensitive enough, precisely because it was not directly testing for HCV.

**27.7** Despite the problems associated with using surrogate tests for the mass screening of donations, with the AIDS crisis and increasing knowledge of the potential seriousness of NANB Hepatitis infection, the arguments for introducing surrogate screening gained ground in the USA. The result was that surrogate screening of donors was first introduced in some centres in 1986 and very widely by 1987. The introduction of surrogate testing in the USA led to further consideration of the issue in Europe, including in the UK. While some European countries introduced surrogate testing of blood donors, most European countries, including the UK, did not.

**27.8** In the event, the issue of surrogate testing was eventually superseded by the identification of the Hepatitis C virus – the virus responsible for most cases of NANB Hepatitis – in 1988 and the subsequent availability of a direct test which detected antibodies to that virus.

## Events in the USA

**27.9** This section sets out in detail the main events in the history of surrogate testing for NANB Hepatitis. Since developments in the USA formed a major element of the background to what happened elsewhere, and in the UK in particular, they are discussed first.

### *Developments in the USA to the end of 1985*

**27.10** Extensive research relating to the aetiology and natural history of NANB Hepatitis in the mid-1970s is discussed in Chapter 15, *Knowledge of Viral Hepatitis 2*. The debate on the effectiveness of screening of blood for ALT elevation and for the presence of anti-HBc as possible indicative markers of NANB Hepatitis infection emerged from that research. The debate took on added significance with the publication in 1978 of an

---

<sup>9</sup> Stevens et al (the TTV study group), 'Hepatitis B virus antibody in blood donors and the occurrence of [NANB] hepatitis in transfusion recipients', *Annals of Internal Medicine*, 1984; 101:733 [LIT.001.3755] and Koziol et al (the NIH study group), 'Antibody to hepatitis B core antigen as a paradoxical marker for [NANB] hepatitis agents in donated blood', *Annals of Internal Medicine*, 1986; 104:488 [LIT.001.1869]

<sup>10</sup> 'Specificity' is a function of a test's ability to identify only the target pathogen.

<sup>11</sup> 'Sensitivity' is a function of a test's ability to capture all cases of infection with the target pathogen.

interim report by the Transfusion Transmitted Viruses (TTV) study group,<sup>12</sup> a project which arose in 1973 from an initiative of the Division of Blood Diseases and resources of the United States National Heart, Lung and Blood Institute, to assess the incidence and cause of post-transfusion viral hepatitis.

### The Transfusion Transmitted Viruses study group

**27.11** The TTV study was a major research exercise that began in 1974.<sup>13</sup> The investigation was initially undertaken at blood transfusion centres in Los Angeles, St Louis and Houston and, from 1976, at the New York Blood Centre.<sup>14</sup> Specimens from all patients enrolled in the study were tested for ALT activity following a standardised protocol and using the same reagents and standards. The same samples were also screened for markers of HBV infection, including anti-HBc.

**27.12** The TTV group's interim report discussed the study of 1307 patients, followed between July 1974 and December 1976. There were 75 episodes of hepatitis among transfused patients, 10 of whom had been infected with HBV. The Inquiry's Terms of Reference did not require detailed discussion of the aetiology or natural history of HBV. The insensitivity of the available tests for Hepatitis B was a significant factor at this time, however, and a number of transfused patients still became infected despite screening. By about 1980 tests for HBV were more sensitive and this problem was materially reduced, though not eliminated. In analysing outputs from their research, the group used sophisticated techniques to identify potential correlations between specific cohorts of donors and recipients, and the ALT and other biometric values found. Volunteer donors alone were selected for this part of the study. Of the various outputs examined, it was found that only the highest donor ALT levels correlated with the development of post-transfusion NANB Hepatitis in recipients and that that correlation was more striking than the relationship with transfusion volume. It was tentatively concluded that there was a possible correlation between donors with markedly elevated ALT and an increased risk of recipients developing post-transfusion NANB Hepatitis.

**27.13** The authors stated:

Since the TTV study is an on-going effort our sample size will continue to grow. Although our study suggests that screening donor units for ALT levels might be useful in reducing the incidence of non-A/non-B posttransfusion hepatitis, the data must be interpreted with caution since the number of patients analyzed to date is small. Also, there are a number of causes for an elevated ALT other than viral hepatitis, one possible reason why 41 of the 75 patients given blood with an abnormal ALT level did not develop evidence of hepatitis in serial follow-up. Furthermore, 30 of the 65 non-A/non-B cases received blood with normal ALT values.

....

Screening volunteer donor units for ALT may be useful in reducing the incidence of hepatitis although further study is warranted.<sup>15</sup>

<sup>12</sup> Aach et al, 'Transfusion-Transmitted Viruses: interim analysis of hepatitis among transfused and nontransfused patients' in Vyas et al (eds), *Viral Hepatitis*, The Franklin Institute Press, 1978, pages 383-396 [PEN.017.0870]

<sup>13</sup> Ibid [PEN.017.0870]

<sup>14</sup> Blood from volunteer donors was used exclusively at the centres in St Louis, Houston and New York. From 1974 to 1976 the Los Angeles centre acquired most of its blood from volunteers but some units were also used from commercial agencies that depended on paid donors.

<sup>15</sup> Aach et al, 'Transfusion-Transmitted Viruses: interim analysis of hepatitis among transfused and nontransfused patients' in Vyas et al (eds), *Viral Hepatitis*, The Franklin Institute Press, 1978, pages 383-396 [PEN.017.0870] at 0882-83

**27.14** In 1978, Dr Harvey Alter and colleagues, who were conducting research at the US National Institutes of Health (NIH) into data on post-transfusion hepatitis from a number of countries, commented on the TTV study:

A finding of potentially great practical import was the observation in the TTV study that 30% of patients with [NANB] hepatitis received one or more blood units with an ALT of greater than 60 International Units/liter. This raises the possibility that donor screening for ALT might prevent some cases of [NANB] hepatitis, but it must be remembered that 70% of non-A/non-B cases received only blood with normal ALT and that 3% [*sic* – 56%<sup>16</sup>] of blood units with elevated ALT did not result in hepatitis. This observation has vast implications for blood banks in that it will increase the time and cost of donor screening and will exclude a significant number of donors who probably do not represent a hepatitis risk. Nevertheless it is a provocative finding ....<sup>17</sup>

**27.15** Alter's group compared the donor ALT levels in their study group of patients with known cases of post-transfusion NANB Hepatitis transmission. They had limited data but commented that their initial findings did not substantiate the correlation suggested by Dr Aach in the TTV paper.

**27.16** Before 1980 therefore, there was no consensus in the USA that ALT testing of donor blood would provide protection against the transmission of NANB Hepatitis.

**27.17** A further report from the TTV study group, entitled 'Serum Alanine Aminotransferase of Donors in Relation to the Risk of Non-A, Non-B Hepatitis in Recipients, The Transfusion-Transmitted Viruses Study,' was published in the *New England Journal of Medicine (NEJM)* on 23 April 1981, ensuring wide circulation of the findings.<sup>18</sup> This second article by Dr Aach and colleagues set out the history of earlier research and the controversy over whether ALT screening would provide an effective, routine method of donor evaluation. In common with other commentators,<sup>19</sup> the TTV study had recognised that the exclusion of HBsAg-positive donors did not eliminate all cases of post-transfusion hepatitis, necessarily implying that an agent other than HBV was responsible for some cases of post-transfusion viral hepatitis. The report stated:

That observation directed the attention of the Study Group back to ALT screening of donors as one approach to reducing further the incidence of hepatitis in recipients ....

....

Systematically collected data for the period 1974 through 1979 now provide substantial evidence that the level of donor ALT is related to the occurrence of [NANB] hepatitis in transfusion recipients. The extent of the association is sufficient to raise the question of whether ALT screening of donors should be reconsidered.<sup>20</sup>

<sup>16</sup> The source of this 3% figure is unclear from the Aach report and appears to be a misprint. The reported data (41/75) suggest that the correct figure was 56%.

<sup>17</sup> Alter et al, 'Non-A/Non-B Hepatitis: a Review and Interim Report of an Ongoing Prospective Study' in Vyas et al (eds), *Viral Hepatitis*, The Franklin Institute Press, 1978, pages 359-369, [PEN.019.0863] at 0868

<sup>18</sup> Aach et al, 'Serum [ALT] of donors in relation to the risk of [NANB] hepatitis in recipients: the TTV study', *New England Journal of Medicine* 1981; 304:889 [LIT.001.0753]

<sup>19</sup> See chapter 25, *Screening of Donated Blood for Hepatitis B* at paragraphs 25.82–25.87

<sup>20</sup> Aach et al, 'Serum [ALT] of donors in relation to the risk of [NANB] hepatitis in recipients: the TTV study', *New England Journal of Medicine*, 1981; 304:889 [LIT.001.0753] at 0753-0754

**27.18** The 1978 findings on ALT were confirmed. The article noted that, by this time, 1513 US transfusion recipients had been followed between 1974 and 1979 to evaluate the incidence of post-transfusion hepatitis and factors influencing its occurrence. The prevalence of post-transfusion NANB Hepatitis was 10%. At lower (low to normal) ALT levels the NANB Hepatitis 'attack rate'<sup>21</sup> was 6% or lower. At higher ALT levels (definitely abnormal) the attack rate rose to 45%. The issue was clearly focused. The authors concluded that ALT testing was a potentially useful method of screening donors to reduce the incidence of post-transfusion NANB Hepatitis. The TTV group stated:

The observations in this report suggest that about 40 per cent of the cases of [NANB] post-transfusion hepatitis among recipients in this study could have been prevented by discarding units with an ALT level in the upper 3 per cent of the distribution (i.e.  $ALT \geq 45$  IU).<sup>22</sup>

**27.19** Having noted that the implementation of ALT testing would reduce the volume of blood available for transfusion, the authors continued:

Consequently, the benefits of initiating ALT screening must be carefully weighed against the number of potential donors that would be excluded, the overall incidence of hepatitis in recipients, and the severity of the disease.

....

Other considerations must be taken into account if widespread ALT testing of blood donors is to be initiated. These include the uncertainty about how long to defer a donor whose blood was rejected, as well as the problems that might occur in the quality control and proficiency of ALT testing on a nationwide basis. Advising donors of the implications of the ALT level would also pose a special problem. In addition, adjustments might have to be made for the observed differences between ALT levels in male and female donors and for the ages of donors. Nonetheless, it appears from this study that screening donor blood to eliminate units with elevated ALT levels would result in a substantial reduction in [NANB] post-transfusion hepatitis.<sup>23</sup>

**27.20** The paper concluded:

Although ALT screening lacks the sensitivity to detect all infectious units and lacks the specificity to detect only infectious units, the high correlation between an elevated ALT level and infectivity of transfused blood provides a compelling argument that such screening should be instituted.<sup>24</sup>

**27.21** In this paper, apart from noting that advising donors of the implications of findings posed a special problem (precisely because the test was a *surrogate* test that might *indicate*, but could not conclusively demonstrate, infection with NANB Hepatitis), little consideration was given to communication with, and care of, donors who were found to have elevated ALT levels.<sup>25</sup>

<sup>21</sup> 'Attack rate' is the cumulative incidence of infection, calculated by dividing the number of people infected by a particular disease by the total number of people in the group being studied.

## The NIH Study

**27.22** The proposal to introduce ALT screening did not meet with unqualified agreement. In an editorial in the same edition of the *NEJM*, Dr Paul Holland and colleagues (from the Clinical Centre Blood Bank, NIH: Dr Alter's group) argued against the immediate introduction of ALT testing.<sup>26</sup> They acknowledged that the TTV study had presented the best evidence to date that blood donors with elevated ALT levels had a significantly increased likelihood of transmitting post-transfusion NANB Hepatitis but argued that the data did not support routine testing. 63% of patients receiving blood with elevated ALT did not get NANB Hepatitis and 7% of patients who received blood with below normal levels of ALT did apparently become infected. Predicting the outcome of implementation was problematical. They concluded that the 'manifold effects' of ALT testing had to be 'thoroughly considered' before wide-spread adoption of what would be an interim measure until specific tests for NANB Hepatitis viruses became available. The editorial commented:

The question is whether ALT testing of all blood donors should become routine. Is the expected benefit to the patient worth the drawbacks, especially to the donors and to the blood-service complex? In other words, what is the practicality of setting up ALT testing, and what is its impact? A number of questions have to be answered before adoption of the ALT test is to be recommended: How can the test be made uniform from one blood bank to the next? Above what level should donors be excluded? What should they be told when rejected, and should they be rejected permanently? Blood banks would have to add the cost of ALT testing to the cost of blood and recruit more donors to replace those rejected. Physicians would be asked to see patients with 'transaminitis'; for most, the cause would not be evident, nor would a treatment be forthcoming; hence there would be no means available to allay the apprehensions of these rejected donors. When compared with the test of hepatitis B surface antigen to detect carriers of hepatitis B, the ALT test is non-specific and would eliminate 10 to 20 times more blood donors. The manifold effects of ALT testing must be thoroughly considered before there is wide-spread adoption of such an interim measure (to be used until specific tests for non-A, non-B viruses become available).<sup>27</sup>

**27.23** At that stage, Dr Alter's group had itself completed a small scale study at the NIH which supported the TTV study group's data (discussed below). It noted that screening blood donors for ALT appeared to be a promising way to decrease the risk of transmitting hepatitis but it did not support the immediate introduction of screening. In substance they advised caution and developed their concerns in the published study report.

**27.24** That NIH study into surrogate testing for NANB Hepatitis was reported on 7 August 1981.<sup>28</sup> In it, 283 transfused patients were prospectively followed up after open heart surgery. All donors in the study were volunteers. Hepatitis<sup>29</sup> developed in 9% of 231 patients who received blood from donors with normal ALT levels. In contrast, hepatitis developed in 29% of 52 patients who received blood from donors with elevated ALT levels. The NIH group stated:

<sup>26</sup> Holland et al, 'Post-Transfusion Viral Hepatitis and the TTVs', *New England Journal of Medicine* 1981, 304:1033-1034 [LIT.001.1630]

<sup>27</sup> Ibid [LIT.001.1630] at 1631

<sup>28</sup> Alter et al, 'Donor transaminase and recipient hepatitis', *Journal of the American Medical Association*, 1981; 246:630 [LIT.001.1817]

<sup>29</sup> As determined by clinical jaundice or elevated ALT in the absence of other likely causes.

The present study ... confirms the significant association of an elevated ALT level in donor blood and the development of recipient posttransfusion hepatitis; it suggests that pre-transfusion screening of donor blood for ALT level can identify some carriers of the NANB hepatitis virus and possibly prevent approximately 30% of transfusion-related hepatitis.<sup>30</sup>

**27.25** The paper went on:

It is important to emphasize the negative aspect of the donor ALT-recipient hepatitis relationship, namely, that 70% of PTH will not be prevented by screening donors for ALT. In addition, 40 (72%) of the 56 donors with elevated ALT levels were not associated with a case of PTH .... These imperfect correlations reflect the non-specific nature of the ALT test and emphasize that adoption of donor ALT screening will, at best, be an interim measure. Continued vigorous pursuit of a specific serological test for the agent or agents of NANB is mandatory.<sup>31</sup>

**27.26** The NIH group concluded:

For the blood recipient, the ALT test offers new hope for hepatitis prevention; for the donor, it offers new information, but perhaps information that is not really desired; for the blood supplier, it increases the complexity and cost of blood delivery and reduces the available amount of a product already in critically short supply. The ALT testing of donors is thus in a tenuous balance between risk and benefit. The balance shifts toward testing when one considers that approximately 30% of PTH might be prevented ... but this is tempered by the realisation that 70% will not be prevented and that even the prevention of 30% is in some doubt unless confirmed by a randomized clinical trial. The balance also shifts away from testing when one considers the estimated additional \$20 million in the annual cost of blood in the United States alone and the potential national loss of 45,000 donors and more than 90,000 blood units. It is a difficult equation, whose solution will require thought and planning.<sup>32</sup>

**27.27** In subsequent correspondence in the following issue of the *NEJM*, the leader of the TTV group, Dr Aach, responded as follows to the suggestion that the recommendation to introduce screening was premature:

The [TTVS] Group did not recommend that routine screening of blood-donor ALT be initiated immediately on the basis of their findings presented in this article. A number of questions that we believed should be answered first were listed in the Discussion section of the paper .... The TTVS paper stressed the non-specificity and relative insensitivity of ALT screening as compared with the potential of a specific serologic assay for a [NANB hepatitis] virus (or viruses). A serologic assay is clearly preferable if and when it becomes available. However, despite more than five years of intensive effort by many investigators a confirmed, reproducible serologic test is not available, and even if it were developed in a research laboratory in the very near future, three to five years would be needed to adapt the test to large-scale screening. Until that time,

<sup>31</sup> Ibid [LIT.001.1817] at 1821

<sup>32</sup> Ibid

screening of donor ALT might provide an interim means to reduce the incidence of [NANB] post-transfusion hepatitis in the United States ....<sup>33</sup>

**27.28** At this stage, then, two highly qualified research groups were converging on the view that ALT testing provided a promising possible approach to testing donor blood in the USA with the objective of limiting NANB Hepatitis virus transmission, pending the introduction of a specific serological test, but neither could mount an adequate argument on scientific grounds to justify immediate general implementation of ALT screening. Further, in its paper of 7 August 1981, the NIH group had developed the suggestion that, if populations with increased exposure to HBV also had increased exposure to the NANB Hepatitis virus, then the presence of antibodies to HBV might be used as an indirect measure of immunity to NANB Hepatitis.<sup>34</sup>

### *Reaction to the studies*

**27.29** Following the 1981 reports by the TTV and NIH groups of a correlation between elevated ALT levels in donors and the development of NANB Hepatitis in recipients, the American Association of Blood Banks (AABB) set up an ad-hoc committee to consider the question of ALT testing of donors.<sup>35</sup> The committee reported in 1982, concluding that the available evidence did not justify testing donors for ALT as a means of reducing the incidence of NANB Hepatitis. The committee listed its main concerns as follows:

1. The measurement of ALT, although a test for one aspect of liver function, is not a specific test for [NANB] hepatitis .... This lack of specificity will result in an intolerably high rate of unnecessary rejections ....
2. No study has shown that the actual elimination of donors with elevated levels of ALT will reduce the incidence of elevated levels of ALT posttransfusion, much less hepatitis ....
3. The significance of elevations of ALT after transfusion is unknown ....
4. There is insufficient information to establish a cut-off level that will separate acceptable from non-acceptable donors ....
5. The methods for ALT testing need to be evaluated ....
6. The effect on the donor base is unknown. The loss of an estimated three per cent of current blood donations may seriously stress the nation's already precarious donor supply. Studies on the effect of such reduction should be available to ensure that severe blood shortages do not cause more morbidity and mortality than might be prevented by universal testing .... More information is needed about the long- and short-term effects of an elevated ALT in otherwise healthy donors so that they and their physicians can be counseled appropriately.<sup>36</sup>

<sup>33</sup> Aach, 'Post-transfusion hepatitis and serum [ALT] in blood donors', *New England Journal of Medicine*, 1981; 305:403 [LIT.001.2156] at 2157

<sup>34</sup> This would be proved wrong: antibodies to NANB Hepatitis/HCV did not imply immunity, but it did anticipate an alternative surrogate test using anti-HBc.

<sup>35</sup> In his evidence to the Inquiry, Professor Leikola described the AABB as 'the leading organisation for transfusion matters in the United States': Day 71, page 14.

<sup>36</sup> 'Report of the AABB *ad hoc* committee on ALT testing', *Transfusion*, 1982; 22:4 [LIT.001.2217] at 2217-2218

**27.30** Alter and Aach's publications were noted in Finland;<sup>37</sup> Australia;<sup>38</sup> Canada;<sup>39</sup> the UK (see below) and elsewhere. In the USA, the results of a detailed economic analysis were published in November 1982.<sup>40</sup> It was concluded that current information about clinically apparent post-transfusion NANB Hepatitis was not sufficient to provide the precision required to estimate the benefits of ALT testing for the purpose of policy decisions. Since there was no randomised prospective study showing that exclusion of blood from donors with elevated ALT levels reduced the incidence of either symptomatic or asymptomatic post-transfusion NANB Hepatitis, there was no way of establishing the appropriateness of the clinical model used in the analysis. Further, these deliberations were taking place against a background in which the natural history of NANB Hepatitis was largely unknown but was generally thought to be not very serious. Five years later this view would be changing.

### The *Vox Sanguinis* forum and widening debate

**27.31** In 1983, *Vox Sanguinis*, the journal of the International Society of Blood Transfusion, asked a number of transfusion doctors for their opinions on the following question: 'Based on your analysis of the benefits and costs of routine donor screening for ALT-GPT<sup>41</sup> to reduce the incidence of post-transfusion non-A, non-B hepatitis in your blood services region, what action would you recommend on this matter?'<sup>42</sup>

**27.32** Dr Aach contributed to the forum.<sup>43</sup> He rehearsed the factors supporting the need for caution, already set out by his TTV group and the NIH group; acknowledged that the cost/benefit ratio could not be assessed; and emphasised the uncertainty around the prospects of developing a specific test. Nevertheless, he argued that a decision could not be postponed indefinitely and, in what became something of a fall-back argument that some action was better than none, proposed that steps should be taken to develop instrumentation and standardisation of procedures with a view to implementing ALT detection. In his view, if a decision could not be taken, then a properly designed randomised study should be initiated immediately and a target date set for testing those donor populations in which an association with post-transfusion NANB Hepatitis had been established. Dr Rainer Müller from Germany, where ALT testing had been routine for many years for identifying parenchymal liver damage,<sup>44</sup> thought that current practice there should not be abandoned.<sup>45</sup>

**27.33** In contrast to Drs Aach and Müller, most of the contributors did not support the introduction of ALT screening of donors without further research, in particular into the actual efficacy of ALT screening in reducing the incidence of post-transfusion hepatitis. In this group were William Bayer (Kansas, USA), Robert Gerety (Office of Biologics, USA

<sup>37</sup> Lagerstedt et al, 'Post transfusion non-A non-B hepatitis in Finland: a prospective study', *Scandinavian Journal of Clinical and Laboratory Investigation*, 1982; 42:567-570 [PEN.018.1141]

<sup>38</sup> Cossart et al, 'Post Transfusion Hepatitis in Australia', *The Lancet*, 1982; 208-211. [SNB.008.0578] Surrogate testing for anti-HBc was also mentioned as a possibility in this article.

FDA), Paul Holland (Clinical Centre Blood Bank, Bethesda, USA), Brian McClelland (SNBTS, Edinburgh), Ruthven Mitchell (SNBTS, Glasgow) and Henk Reesink and Eveline Reerink-Brongers (Amsterdam, Netherlands).<sup>46</sup>

**27.34** In a review article published in September 1983, Dr Jules Dienstag (Massachusetts General Hospital and Harvard Medical School) discussed the options for surrogate testing that had emerged by that date.<sup>47</sup> For present purposes it is sufficient to note his views on testing for the Hepatitis B surface antigen (anti-HBs), anti-HBc and ALT.<sup>48</sup> He was dismissive of anti-HBs testing, essentially on the grounds that there had been no confirmation of an association between anti-HBs in donor blood and enhanced risk of post-transfusion hepatitis in recipients. Relying on data from the TTV Study group, he commented that anti-HBc could theoretically serve as an indirect donor screening test: recipients of at least one unit of blood with anti-HBc were three times more likely to acquire NANB Hepatitis after transfusion than recipients of blood that was all negative for anti-HBc. The test would, however, involve the loss of twice the blood lost in ALT testing, without a corresponding advantage in recipient safety. His conclusions were:

If prospects for a specific test for NANB hepatitis were bright, this interim test might not be worth considering. On the other hand, an intensive search for serologic markers begun a decade ago has yet to bear fruit, and as many as 5–10 yr may pass before a specific, sensitive screening test is developed and introduced into practice. Therefore, despite the poor sensitivity and predictive value of the test, and despite the difficulties and questions generated by a policy of screening, ALT screening may be warranted until NANB-specific tests become available.<sup>49</sup>

**27.35** Dienstag noted that, although no policy to adopt ALT testing had been adopted officially, several large centres in the USA were screening and withholding blood with high ALT levels. Prospective studies were planned.

### *Continuing debate to 1986*

**27.36** The *Vox Sanguinis* forum was inconclusive but stimulated further debate. The data from the TTV Study that formed the basis of an association between raised ALT levels in donors and an increased risk of transfusion recipients developing NANB Hepatitis, were taken up and studied again in 1984 by Dr Cladd Stevens and others (New York and other US centres).<sup>50</sup> This group analysed the data to test the hypothesis that '[e]pidemiologic circumstances predisposing donor populations to infection with hepatitis B virus may also favour exposure to [NANB] agents'. The issue was whether patients who received blood from donors who tested positive for anti-HBs and anti-HBc were at increased risk of developing NANB Hepatitis.

<sup>46</sup> While expressed more equivocally, this also appears to have been the view of Chataing et al (Lyon and Toulouse, France). Responses to ALT survey *Vox Sanguinis*, 1983; 48 [LIT.001.1837] at 1851-3.

<sup>48</sup> Various tests for Hepatitis B had been developed or were under development at this time. See Chapter 25, *Screening of Donated Blood for Hepatitis B*, paragraphs 25.28–25.31.

<sup>49</sup> Dienstag, 'Non-A, Non-B Hepatitis. II. Experimental Transmission, Putative Virus Agents and Markers and Prevention', *Gastroenterology*, 1983; 85:743-68 [LIT.001.1213] at 1229

<sup>50</sup> Stevens et al, 'Hepatitis B virus antibody in blood donors and the occurrence of [NANB] hepatitis in transfusion recipients', *Annals of Internal Medicine*, 1984; 101:733 [LIT.001.3755]

**27.37** The authors reported an association between units of donor blood that were positive for anti-HBc and an increased risk of recipients developing NANB Hepatitis. Elevated ALT levels in donors had a similar association with NANB Hepatitis in recipients but would have resulted in fewer units of blood being discarded than would screening for anti-HBc (2.8% as against 5.1%). They did not find a statistically significant association between donors who were positive for anti-HBs and the development of NANB Hepatitis in recipients. The authors considered that 21.4% of cases of NANB Hepatitis might have been prevented by screening for anti-HBc, 29.9% of cases might have been prevented by screening for ALT and 39.2% of cases might have been prevented by screening for both anti-HBc and ALT. Adjusting these figures to take into account the incidence of NANB Hepatitis in non-transfused control patients resulted in figures of 33.3%, 47.4% and 61.2% respectively. Screening for both ALT and anti-HBc would have resulted in a loss of nearly 8% of donor units.

**27.38** The authors emphasised that their calculations were only rough estimates of the potential impact of donor screening based on their data. Other critically important factors affecting the risk to recipients – such as the prevalence of NANB Hepatitis among donors and the susceptibility to infection among recipients – remained unknown in the absence of specific serological tests and were presumed to vary among both donor and recipient populations.

**27.39** The paper noted that only eight per cent of anti-HBc positive donors had elevated ALT levels, with the result that ‘these two markers identified overlapping, but different, donor subsets’.<sup>51</sup> Having regard to the lesser quantity of blood that would be discarded by ALT screening when compared with anti-HBc screening, it was noted that ‘the consensus of the study group is that ALT screening of donors is favored over anti-HBc screening’.<sup>52</sup>

**27.40** The same edition of the *Annals of Internal Medicine* also contained the following commentary by Drs Alter and Holland on the TTV study group findings:

The possibility that a specific marker for anti-HBc might be useful in detecting carriers of the [NANB] virus was an unexpected and confounding outcome of the TTV study. Of the potential explanations for this observation, the one favored by the TTV group is that persons exposed to the hepatitis B virus are also more likely to have been exposed to the [NANB] virus and, hence, that a marker for one is indirectly a marker for the other. This assumption would be more tenable if the same association could be shown for antibody to hepatitis B surface antigen (anti-HBs) because anti-HBs is an equally good indicator of past exposure to hepatitis B virus. However, in the TTV study, recipients of only anti-HBs positive blood were not at higher risk for [NANB] hepatitis, and in three previous studies no significant association between donor anti-HBs and recipient hepatitis was demonstrable.

....

If both the tests for ALT and anti-HBc are indirect indicators of the [NANB] carrier state, one by detecting subclinical liver disease and the other by indicating the likelihood of virus exposure, then both tests should detect the same

---

<sup>51</sup> Ibid [LIT.001.3755] at 3757

<sup>52</sup> Ibid [LIT.001.3755] at 3759

[NANB] hepatitis carrier population. In fact, the tests do not .... These tests are identifying two different, seemingly high-risk populations. This dichotomy is disturbing, suggesting either that the tests are not really detecting carriers of [NANB] hepatitis and that their apparent association with [NANB] hepatitis is a statistical artifact, or that they are detecting two different carrier populations perhaps harbouring different agents for [NANB] hepatitis.<sup>53</sup>

**27.41** Alter and Holland commented as follows on the efficacy of surrogate testing:

The key question in this study is test efficacy: How effective would anti-HBc testing of donors be in preventing cases of transfusion-associated hepatitis? Unfortunately, true efficacy cannot be determined from this study or from the previous studies of ALT because none were randomized, controlled trials that compared tested blood with untested blood.<sup>54</sup>

**27.42** The reason for any association between anti-HBc in donors and an increased risk of NANB Hepatitis in recipients thus was, and in fact remains, something of a puzzle, as was the lack of overlap between the groups of subjects testing positive for elevated levels of ALT and anti-HBc. In his evidence to the Inquiry, Dr John Gillon, SNBTS, said:

[T]his has always been a huge puzzle to me and it's one of the things that instinctively did not make sense about this whole business. There should be a very considerable overlap, and there just isn't. And I think reading [what] Harvey Alter said then<sup>55</sup> is what I felt. And I do remember at the time ... I tried to stratify theoretical hundreds of donors into categories who got 1 unit of blood, 2 units, 10 units, 20 units and worked on different prevalences of the putative infection, the ALT, [anti-HBc] and stratified them. And I became convinced that a lot of the association was coincidental, that it was entirely – well, not entirely but at least substantially a function of having a large volume of transfusion, so that ... patients who got, say, 15/20 units of blood at given prevalences were much more likely to get one thing and the other thing, more or less by coincidence, compared with people who only got one unit of blood, when it was much more unlikely that there would be a coincidence.

....

So I still don't have a satisfactory explanation for that, but it was part of the instinctive feeling that there was something going on here which was not just about you use a test and you identify somebody who might transmit [NANB] Hepatitis. So it was not as simple as that. And I remain convinced there was a statistical artefact. That doesn't mean that identifying people with high ALT wouldn't have prevented Hepatitis C but it does call into question the exact relationship between the two and the exact outcome if you did it prospectively.<sup>56</sup>

<sup>56</sup> Day 65, pages 94 – 96

**27.43** In due course, later studies were carried out to investigate whether there was an association between donors testing positive for anti-HBc and an increased risk of NANB Hepatitis in recipients. While some studies found such an association,<sup>57</sup> others did not.<sup>58</sup> Of these later studies, the NIH study<sup>59</sup> investigated whether the presence of antibodies to HBsAg in the donor correlated with the development of NANB Hepatitis in the recipient and, like the TTV study, found that it did not.

**27.44** Dr Alter's views on surrogate testing in 1985 were as follows:

The question of whether or not the ALT test should be routinely adopted for donor screening was widely debated and currently remains an essentially unresolved issue. Inherent in the debate were questions as to whether the predicted efficacy could actually be achieved in clinical practice, and questions relating to test standardization, non-specificity, responsibility to the donor and the ability to sustain the donor loss which would ensue. The major organizations of the national blood delivery complex, ARC,<sup>60</sup> AABB<sup>61</sup> and CCBC,<sup>62</sup> opted not to adopt routine donor ALT testing until additional data were available, whereas the New York Blood Center initiated such testing and subsequently proved its feasibility though they did not accumulate additional efficacy data.<sup>63</sup>

**27.45** Dr Alter referred to a small-scale prospective study carried out by the NIH into the impact of ALT testing on the incidence of post-transfusion hepatitis. In 1981 the NIH had introduced ALT testing and had excluded all blood donations with high ALT levels. Perhaps surprisingly, it was found that '[t]he incidence of NANB hepatitis in the 3 years post-ALT testing was virtually identical in both patients and non-transfused controls to that in the 2 years prior to ALT testing'. That is, there was no significant decline in the incidence of hepatitis after ALT testing was introduced. Alter observed that, therefore, '[e]fficacy cannot be reliably predicted; it must be randomly and prospectively demonstrated'.<sup>64</sup>

**27.46** Dr Alter set out three options in respect of ALT testing: (i) to decide that existing data were inconclusive and that, given the difficulties with ALT testing, it was best not to adopt such screening at that time; (ii) to decide that, although the data relating to ALT efficacy were not definitive, they were scientifically valid and, overall, were sufficiently compelling to warrant the introduction of donor testing and (iii) to decide that existing data were inconclusive but were sufficiently compelling that a definitive answer must be sought by means of a randomised, controlled study, to be instituted as rapidly as

<sup>57</sup> Studies which found such an association included: Koziol et al (Alter's NIH group), 'Antibody to hepatitis B core antigen as a paradoxical marker for [NANB] hepatitis agents in donated blood', *Annals of Internal Medicine*, 1986; 104:488 [LIT.001.1869]; Hyland et al (Australia), 'Predictive markers for hepatitis C antibody ELISA specificity in Australian blood donors', *Transfusion Medicine*, 1992; 2:207 [LIT.001.3794]; Sugg et al (Germany), 'Antibodies to hepatitis B core antigen in blood donors screened for [ALT] level and hepatitis [NANB] in recipients', *Transfusion*, 1988; 28:386 [LIT.001.3813].

<sup>58</sup> Studies which found no such association included: Aynard et al (France), 'Post-transfusion [NANB] Hepatitis after cardiac surgery: prospective analysis of donor blood anti-HBc antibody as a predictive indicator of the occurrence of [NANB] hepatitis in recipients', *Vox Sanguinis*, 1986; 51:236 [LIT.001.3810]; Van der Poel et al (the Netherlands), 'Infectivity of blood seropositive for hepatitis C virus antibodies', *The Lancet*, 1990; 335:558 [SNB.001.9850]; Esteban et al (Spain), 'Evaluation of antibodies to hepatitis C virus in a study of transfusion-associated hepatitis', *New England Journal of Medicine*, 1990; 323:1107 [LIT.001.3892]; Ebeling (Finland), 'Alanine Aminotransferase, Gamma-Glutamyltransferase, Antibodies to Hepatitis B Core Antigen and Antibodies to Hepatitis C virus in blood donor screening', *Vox Sanguinis*, 1991; 60:219 [PEN.017.1763].

<sup>59</sup> Koziol et al (Alter's NIH group), 'Antibody to hepatitis B core antigen as a paradoxical marker for [NANB] hepatitis agents in donated blood', *Annals of Internal Medicine*, 1986; 104:488 [LIT.001.1869].

<sup>64</sup> Ibid [LIT.001.0811] at 0819-20

possible. Dr Alter noted that implicit in the second option was the assumption that 'if an interpretive error is to be made, it is best to err on the side of recipient safety and that to withhold such testing is ethically unjustified'.<sup>65</sup>

**27.47** Dr Alter's preference was for the third option:

It is my opinion that option 3 is the most tenable alternative. Had this controlled study been performed three years ago when first proposed, a definitive answer would be at hand. Instead, the same uncertainties persist. A randomized, controlled trial could be completed in 1½ years, could address both the ALT and anti-core issues and could provide a definitive and rational basis for making these complex decisions. Even at this late date ... we find ourselves still far from the core (or the ALT) of this issue.<sup>66</sup>

**27.48** In the period 1984–85, therefore, scientific opinion in the United States remained divided on the usefulness of surrogate testing, whether for anti-HBc or for ALT. Neither could be fully justified on scientific criteria alone but practical steps were beginning to be taken by some blood transfusion organisations to implement ALT testing – an understandable approach in a litigation-driven society such as the USA. In the event, no definitive controlled study, as proposed by Alter, was ever carried out in the USA.

### **1986: A change of direction in the USA**

**27.49** On 21 February 1986, *Blood Bank Week*, the official publication of the AABB, reported that:

The Blood Products Advisory Committee of the Food and Drug Administration will recommend that both ALT and anti-core testing be performed on donated blood to reduce the incidence of transmission of [NANB] hepatitis through transfusion. In a February 13-14 meeting, the panel received reports on two studies showing that recipients of blood from donors with elevated ALT and anti-core had a higher incidence of NANB hepatitis.<sup>67</sup> While questions were raised about the data, it was noted that the carrier rate of NANB is higher than previously thought, that cases are underreported and that NANB is now considered to be a much more serious disease.<sup>68</sup>

**27.50** The views of Dr Alter on the introduction of surrogate testing appear to have changed around this time. While, as discussed above, Dr Alter had expressed the view in 1985 that a randomised prospective study into the efficacy of surrogate testing in reducing the incidence of post-transfusion hepatitis should first be carried out, in February 1986 he co-authored a paper with Dr Dienstag in which the opinion was expressed that, despite the negative features of ALT and anti-HBc screening already reported:

[T]he accumulating data that chronic NANB hepatitis leads to cirrhosis in 10 to 20% of cases has served as compelling evidence for the need to rely on indirect assays as an interim measure until such time as specific NANB hepatitis

---

<sup>65</sup> Ibid [LIT.001.0811] at 0821

<sup>66</sup> Ibid [LIT.001.0811] at 0822. In fact, these three options and the conclusion had first appeared in the December 1984 editorial by Alter and Holland noted above; Alter and Holland, 'Indirect tests to detect the [NANB] hepatitis carrier state', *Annals of Internal Medicine*, Dec 1984; 101:859 [PEN.018.1156]

<sup>67</sup> Presumably a reference to the TTV and NIH studies

<sup>68</sup> 'FDA advisory panel recommends surrogate testing for NANB', *Blood Bank Week*, February 21, 1986 [SGF.001.0783] at 0784

assays are developed .... [I]ncreasing documentation of the chronic sequelae of NANB hepatitis and the continued high incidence of this disease after transfusion have tipped the balance in favour of adopting indirect assays for NANB hepatitis carrier detection.

....

Specific therapy for either acute or chronic NANB hepatitis is not available .... In the absence of effective treatment, the need for prevention assumes even greater importance.<sup>69</sup>

**27.51** In this careful review no new scientific evidence was produced to support a change of opinion on the sensitivity or specificity of either surrogate test for NANB Hepatitis. The major participants in the 'blood delivery complex' were at the time considering the adoption of either the ALT test or the anti-HBc test or both. Dr Alter might be thought to have bowed to the inevitable consequences of pressure from the blood delivery complex, although increasing evidence of the potential seriousness of NANB Hepatitis infection emerging in the USA and Europe, compared to what had been perceived to be the position about four years earlier, was clearly influential and was taken into account in this landmark opinion. A similar view was expressed by Dr Alter's NIH group in April 1986 when the authors re-visited their earlier data to investigate further the association between anti-HBc in donor blood and the development of transfusion-associated hepatitis.<sup>70</sup>

**27.52** Two factors entered into the decision whether to adopt either test: the unlikelihood that a specific test would become available in the near future and the developing knowledge of the severity of NANB Hepatitis. It was now estimated that up to 7500 cases of cirrhosis might be induced annually in the USA by NANB Hepatitis. The high risk of developing progressive liver disease resulting in serious liver damage tipped the balance for Dr Alter's group:

If, as predicted, surrogate screening of blood donors could prevent approximately one third of these cases [of NANB Hepatitis], then this could represent an annual reduction of 50000 cases of hepatitis and 2500 cases of cirrhosis. The potential to achieve this degree of disease prevention now appears to outweigh the disadvantages inherent in the adoption of surrogate tests for the [NANB] virus carrier state.<sup>71</sup>

**27.53** In August 1986, the AABB recommended that all donor blood be tested for ALT and anti-HBc with effect from 30 November 1986 in an attempt to reduce NANB Hepatitis transmission.<sup>72</sup> Despite the difficulties with surrogate screening, the AABB believed that 'the importance of a potential increase in the safety of the blood supply outweighs the negative aspects of this testing'. As discussed so far, the scientific basis for this view remained questionable but the perceived interests of patient recipients had influenced the decision.

<sup>72</sup> AABB statement dated 15 August 1986 [PEN.016.0312]

**27.54** In his evidence to the Inquiry, Professor Juhani Leikola of the Finnish Red Cross Blood Transfusion Service accepted that patient safety was a factor behind the introduction of surrogate testing in the USA.<sup>73</sup> However, the impression of the experts attending the meeting of the Expert Committee of the Council of Europe in May 1987, discussed below, was that the decision in the USA to introduce surrogate testing had also been taken for non-scientific reasons, in particular because the transfusion community had been criticised for being slow to react to the AIDS crisis and because of the fear of litigation. He also stated that the information from the TTV and NIH studies had made it clear that NANB Hepatitis was a serious risk associated with transfusion.<sup>74</sup> He explained that important factors in the USA were ‘the higher incidence’ of NANB Hepatitis than seemed likely in northern Europe and also ‘public opinion and media coverage’.<sup>75</sup>

**27.55** Surrogate testing was introduced generally in the USA between 1986 and 1987. In an article published in *Nature* on 4 September 1986, the positions adopted by the major bodies were summarised.<sup>76</sup> The AABB, as noted above, expected its members to implement surrogate testing (apparently by raised ALT levels) of all donated blood, by 30 November 1986. The American Red Cross was also implementing ALT testing at its blood banks. Its programme had begun on 7 July and was expected to be completed by 1 October 1986. A third organisation, the Council for Community Blood Centers (CCBC), had not officially declared a position on ALT testing but its President was reported as saying that ‘most members [would] go ahead with ALT testing’. The article stated that the use of anti-HBc testing was far more contentious. A major concern for all blood centres was the loss of donors due to false positives in both surrogate tests and the cost of testing. Notwithstanding these concerns, the President of the AABB considered that the tests were ‘essential to increase the safety of the blood supply’.<sup>77</sup>

**27.56** Throughout the period of developing thought, from the paper by Aach and others in 1981 to the observation of the AABB last quoted, the emphasis was on reducing risk for transfusion recipients. There was relatively little discussion of the implications for *donors* found to have significantly elevated ALT levels or of the need for care and counselling of such donors.

**27.57** For the time being that concluded the issue in the USA. The history provides an appropriate point of reference for discussing events in Europe where, among other significant differences, there was considerably more concern about donors’ interests.

### The European response

**27.58** In his written evidence to the Inquiry, Professor Leikola set out the position in Europe in the early to mid-1980s, referring in the first place to the AABB view in 1982 that ALT screening of donors was not justified:

In the early 1980’s the conclusion by the AABB ad hoc committee was considered reasonable, and there was no move in Europe to introduce surrogate testing.

<sup>73</sup> Day 71, pages 25–26. Professor Leikola was a former Director of the Finnish Red Cross and spent a number of years as head of the Blood Programme of the League of Red Cross and Red Crescent Societies in Geneva.

<sup>74</sup> Day 71, pages 19–23

<sup>75</sup> *Ibid* page 24

<sup>76</sup> Palca, ‘Hepatitis screening extended’ *Nature*, 1986; 323:7 [SGF.001.2108]

<sup>77</sup> On the question of surrogate testing in the USA, see also the memorandum dated 27 June 1986 by Dr Sandler, Associate Vice President, Medical Operations of the American Red Cross, on the phase-in of ALT testing [SGF.001.2123]. See also the memorandum dated 4 September 1986 by Dr AuBuchon, Medical Officer, Medical Operations, American Red Cross, on ALT cut-off values [SGF.001.2113].

It was recognized that the incidence of NANBH varied from country to country and in different donor populations. In northern parts of Europe there were less cases of NANBH than in the south, and there were differences between urban and rural populations. Australia was considered to belong to the lowest prevalence countries, similar to Northern Europe and dissimilar to the United States.

There was a general feeling that more information was needed of the possible correlation between screening for surrogate markers and prevention of NANBH. The journal *Vox Sanguinis* published in 1983 nine short articles .... All contributors took a cautious view on ALT screening.

....

The American finding that anti-HBc correlated with NANBH was disturbing and could not be explained .... There were soon reports appearing, notably from France, the Netherlands and the United Kingdom, showing that in the European donor populations studied anti-HBc did not correlate with recipient NANBH. The pattern was clearly different from the American donors: Incidence of NANBH much less and anti-HBc meaningless as a surrogate marker. There was some association between elevated ALT and recipient NANBH, but its efficacy as a possible surrogate test was considered weak. This view was supported by the negative findings of the NANBH incidence after ... ALT screening in Germany on one hand and in the New York Blood Center and at the NIH on the other.<sup>78</sup>

**27.59** There was soon progress. Professor Leikola continued:

After the American organizations decided to recommend the introduction of routine ALT and anti-HBc testing it was necessary to decide also in European countries whether or not to follow ... suit. There was a consensus among the scientific and blood transfusion expert community that prospective studies were urgently needed before a decision could be taken.<sup>79</sup>

**27.60** The Council of Europe Committee of Experts on Blood Transfusion and Immunohaematology met in May 1987.<sup>80</sup> The general impression from the returns to questionnaires sent to Member states was that the incidence of NANB Hepatitis was rather low but varied widely among different regions. The value of surrogate tests such as ALT and anti-HBc had been studied by various groups but there was doubt about their cost and effectiveness. After discussion by the Committee, it was decided that a working group would prepare a report and, if possible, make recommendations. In due course the working group reported and, in summary, concluded:

(i) The use of a non-specific test for the purpose of reducing the incidence of transfusion-associated NANB Hepatitis and its possible value as a public health measure remained controversial issues.

---

<sup>78</sup> Professor Leikola's statement on surrogate testing [PEN.017.1837] at 1839

<sup>79</sup> Ibid [PEN.017.1837] at 1839-40

<sup>80</sup> Council of Europe: extract from the report of the Committee of Experts on Blood Transfusion and Immunohaematology, 19-20 May 1987 [SNB.001.9445]. The working group comprised Professor van Aken (Holland), Dr Gunson (UK), Dr Habibi (ISBT) and Dr Leikola (Finland).

(ii) If a stance was taken that blood should be as safe as possible, then tests would be introduced, but the benefits derived from this testing would not be uniform throughout every country. There was also no guarantee that, in a given country, there would be a significant reduction in the transmission of NANB Hepatitis.

(iii) The introduction of non-specific tests might compromise the blood supply and this was a factor which had to be taken into account.

(iv) When non-specific testing was introduced in a country, provision would have to be made for the interviewing, counselling and further medical examination and treatment which might be required for donors found to have raised ALT levels or who were anti-HBc positive.

(v) The Committee could not make a general recommendation on the routine introduction of non-specific tests for evidence of the NANB Hepatitis infectivity of blood donors. Individual countries would have to assess the situation locally and decide on the appropriate action to take.<sup>81</sup>

**27.61** In his written evidence to the Inquiry Professor Leikola stated:

Most countries that I know elected in 1987 not to blindly follow what the Americans did but to first find out the situation in their own donor population. Thus, the attitude towards surrogate testing was not negative per se, but before making a decision in Europe the expert community wanted to know whether the concept would really produce results.<sup>82</sup>

**27.62** Professor Leikola explained that, in Finland, the decision of the US blood banks in 1986 to commence surrogate testing prompted further consideration of the issue by the Finnish blood transfusion service which, in 1987, decided to undertake a new study 'to determine the current incidence and types of post-transfusion hepatitis among open-heart surgery patients from all parts of Finland.' A second objective was 'to obtain donor samples for future evaluation of possible preventive strategies'.<sup>83</sup> A doctoral student was engaged to organise the study and the service had the resources to collect and analyse the samples.<sup>84</sup> The study began in the beginning of December 1987 and lasted one year. It was carried out at all five of the Finnish university hospitals and included 685 patients and 8346 donors. Several candidate surrogate markers were investigated, as were (retrospectively) tests for antibodies to HCV once they became available.<sup>85</sup> A correlation between elevated ALT levels in donors and an increased incidence of post-transfusion NANB Hepatitis in recipients was established.<sup>86</sup> In his oral evidence Professor Leikola said that Finland did not introduce ALT testing before the study was done and that that reflected the general view in the mid-1980s of the European transfusion community, that surrogate testing was not something to be started without first performing such a study.<sup>87</sup>

<sup>83</sup> Ibid [PEN.017.1837] at 1841

<sup>84</sup> Day 71, page 52

<sup>85</sup> The findings of the study are discussed above: Ebeling, 'Alanine Aminotransferase, Gamma-Glutamyltransferase, Antibodies to Hepatitis B Core Antigen and Antibodies to Hepatitis C virus in blood donor screening', *Vox Sanguinis*, 1991; 60:219 [PEN.017.1763]

<sup>86</sup> Day 71, page 56

<sup>87</sup> Ibid pages 61–62. The study also found that Ortho's HCV test appeared to detect post-transfusion NANB Hepatitis in recipients and in positive donors.

**27.63** The situation in Europe generally in 1989 was set out in a document compiled by Dr Harold Gunson<sup>88</sup> on behalf of the Council of Europe's Committee of Experts following their meeting in May 1989. Significantly, by this stage it was known that Chiron had discovered HCV (see paragraphs 27.238–27.241 below) and that an anti-HCV test had been developed (see Chapter 31, *The Introduction of Screening of Donated Blood for Hepatitis C*). The document stated:

1. Replies to the questionnaire were received from 10 countries.
2. Examination of the replies revealed that in 4 countries routine screening of donations with ALT is being performed. These countries are the Federal Republic of Germany, France, Malta and Switzerland. Anti-HBc is routinely performed in France.
3. There are several studies being undertaken in some countries to determine the policies which should be undertaken to protect the blood supply with respect to the transmission of [NANB] hepatitis. These countries are Denmark, Norway, United Kingdom and Finland.
4. There is clearly an interest in the Chiron anti-HCV test and several countries are planning to conduct trials with this test.
5. There is a potential difficulty with respect to the use of the surrogate ALT and anti-HBc testing of donations with particular reference to source plasma for fractionation. The practice of routine ALT testing by the Federal Republic of Germany for many years means that plasma or its fractions, cannot be imported into that country unless the starting plasma has been ALT tested. This could have considerable implications for the standardisation of the quality requirements for plasma in 1992.<sup>89</sup>

**27.64** In his evidence to the Inquiry Professor Leikola explained:

In Europe, France was one of the few countries which decided to go for surrogate testing any way. ALT testing became mandatory in April 1988. In the aftermath of the "tainted blood affair" (HIV contaminated blood) the decision is understandable. It was not motivated by ... scientific knowledge but by ... political necessity. Something had to be done, whether or not it truly reduced the risk of NANBH transmission by blood. Northern countries with low NANBH incidence such as the Netherlands, Denmark, Norway, Sweden and Finland decided not to introduce surrogate testing before more was known of the efficacy in the respective donor populations. There were many articles published by UK authors in the *Lancet* and *Vox Sanguinis* advising against a hasty introduction of surrogate testing.<sup>90</sup> These opinions in the prestigious medical journals were not without influence in the international community.<sup>91</sup>

<sup>88</sup> Chairman of the UK Advisory Committee on Transfusion Transmitted Diseases (ACTTD), discussed below, from October 1989. Dr Gunson became Chair in February 1989.

<sup>90</sup> Anderson et al 'Surrogate testing for [NANB] hepatitis', *The Lancet*, 1987:912 [LIT.001.1854]; Dow et al, '[NANB] hepatitis surrogate testing of blood donations', *The Lancet*, 13 June 1987 [LIT.001.0346]; Gillon et al, 'Post-transfusion [NANBH]: significance of raised ALT and anti-HBc in blood donors', *Vox Sanguinis*, 1988; 54:148–153 [SNB.008.3536]

<sup>91</sup> Professor Leikola's statement on surrogate testing [PEN.017.1837] at 1840

**27.65** Professor Leikola agreed with the suggestion that the introduction of surrogate testing was 'a sort of emotional reaction to the situation that says we really have to do something, rather than a scientific or logical answer to the situation'.<sup>92</sup>

**27.66** In a 2001 court case, *A v The National Blood Authority and others*,<sup>93</sup> it was noted that, '[n]ot many countries apart from the United States (both tests) and Germany (ALT only) introduced surrogate tests'.<sup>94</sup> The full picture was stated to be as follows:

**Table 27.1: Introduction of Surrogate Testing**

Germany	1965	ALT <sup>95</sup>
Italy	1970	ALT <sup>96</sup>
USA	Sep 1986 onwards	Both <sup>97</sup>
Luxembourg	1 Oct 1986 Mid 1987 onwards (for new donors)	ALT Anti-HBc
France	15 April 1988 3 Oct 1988	ALT Anti-HBc
Switzerland	1 June 1988	ALT
Malta	Early 1989	ALT

**27.67** It was also noted that:

There was some partial routine ALT testing in certain centres in Austria, Belgium and Spain, from about 1987, and Queensland (alone of the Australian states) introduced compulsory ALT testing in about April 1989. Dr Högman told the Council of Europe in 1987 that Sweden was to introduce anti-HBc testing for first time donors, but he explained in evidence that this was intended in fact as a supplementary Hepatitis B screening. No other countries, so far as is known, ever introduced either test.<sup>98</sup>

**27.68** From the above, it is apparent that most European countries did not introduce surrogate testing of blood donors on account of the association of ALT with NANB Hepatitis<sup>99</sup> and that, with the exception of France, those that did carried out their own preliminary evaluations before doing so.

<sup>92</sup> Day 71, page 33

<sup>93</sup> The claimants in *A v National Blood Authority* contracted Hepatitis C as a result of treatment with blood and blood products and sought damages in the English courts relying on the strict liability provisions of the Consumer Protection Act 1987 (the Act is discussed below). While the ultimate findings of the court are not directly relevant to the Inquiry (given that they are based on different evidence, for a different purpose, in a different forum), some of the evidence noted in the judgment of Mr Justice Burton is of assistance and, where relevant, has been noted in this Report. The full Judgment is reported at [2001] 3 All ER 289 [PEN.017.0302].

<sup>94</sup> *A v The National Blood Authority*, [2001] 3 All ER 289, paragraph 108(v) [PEN.017.0302] at 0369

<sup>95</sup> In his evidence to the Inquiry Professor Leikola stated his understanding that ALT was gradually introduced in every region in Germany. He also stated that German transfusion doctors remained sceptical about the efficacy of ALT screening: Day 71, pages 7 and 10

<sup>96</sup> Professor Leikola told the Inquiry that it was unclear whether every region in Italy had introduced ALT testing: Day 71, pages 8-9

<sup>97</sup> In his evidence to the Inquiry Dr Gillon stated: '[I]n the USA, in fact they didn't introduce [anti-HBc] testing in 1986 as planned because core testing was technically difficult and they were having problems with reproducibility. I'm not sure it was ever universally introduced but if it was, it was certainly not before the middle of 1987.' Day 65, page 80

<sup>98</sup> *A v The National Blood Authority*, [2001] 3 All ER 289, paragraph 108(v) [PEN.017.0302] at 0369

<sup>99</sup> As noted in paragraph 27.32, ALT testing in Germany had a particular long standing purpose unrelated to the postulated association with NANB Hepatitis.

**27.69** As reflected in Professor Leikola's evidence, there were particular concerns about the relevance of the anti-HBc test. There seemed to be no logical basis for a correlation between the presence of antibodies to one disease in donors (Hepatitis B) and the presence of a different disease in recipients (NANB Hepatitis). The most plausible theory appeared to be based on 'lifestyle' factors, in that a donor whose lifestyle (such as injecting drug use) exposed them to HBV infection might have been at a higher risk of being exposed to other blood borne diseases such as NANB Hepatitis. The difficulty with that hypothesis was that, if it were correct, one would also have expected there to be a correlation between the presence of HBsAg in donors (which was an indicator of Hepatitis B infection) and recipient incidence of NANB Hepatitis. The TTV and NIH studies did not find such a correlation. In addition, while some studies showed a correlation between donor anti-HBc and recipient NANB Hepatitis, other studies showed no such correlation.<sup>100</sup>

**27.70** As regards the possible correlation between anti-HBc and NANB Hepatitis, Professor Leikola observed:

[M]ost people thought that ... it really doesn't make any sense and therefore these European studies that showed that there was no correlation between [anti-HBc] and [NANB] Hepatitis was, for me at least, a relief, to see that ... it wasn't logical to include hepatitis core antibody in this whole exercise, and therefore I was quite happy to see that it was confirmed in our material and also in the other European [studies].<sup>101</sup>

**27.71** To this day it is quite unclear why some studies found this association.

### The position in the United Kingdom

**27.72** Having regard to the variety of positions adopted in Europe, it is clearly necessary to consider developments in the UK specifically. There are, however, some points that should be kept in mind. Until the developments in 1986 described above, there was no consensus in favour of the adoption of surrogate testing in the USA and still less in Europe. When the introduction of surrogate testing became a real issue for blood transfusion services, following the advice of the AABB in the USA, it was recognised that the decision for individual regions had to be taken in light of local factors that required specific investigation. There were also other developments that would inevitably have had a bearing on the course adopted. For example, in the UK progress with virus inactivation would inevitably have become a consideration in assessing the cost/benefit balance of implementation as far as blood products (particularly coagulation factor concentrates) were concerned.

#### 1970s to early 1980s

**27.73** In the late 1970s there were no reliable data on the prevalence of NANB Hepatitis in the UK. The Medical Research Council (MRC) report published in 1974 has already been mentioned.<sup>102</sup> In his evidence to the Inquiry, Dr McClelland stated that when he read the 1974 study in the early 1980s he realised that it did not really tell relevant practitioners what they needed to know.<sup>103</sup>

<sup>100</sup> Professor Leikola agreed with the suggestion that part of the reason for that may have been that the TTV and NIH studies were carried out before steps had been taken to try to exclude donors at risk of transmitting AIDS, whereas some later studies were carried out after donors had been excluded by these steps and that the lifestyles of these excluded donors may have meant that they were both more likely to be anti-HBc positive and were at a higher risk of transmitting NANB Hepatitis: Day 71, pages 35-36 Day 71, page 35

<sup>102</sup> Medical Research Council, 'Post-transfusion hepatitis in a London hospital', *Journal of Hygiene*, 1974; 73:173-188 [LIT.001.0116] The report is discussed more extensively in Chapter 14, *Knowledge of Viral Hepatitis 1*, Paragraphs 14.19-14.22.

<sup>103</sup> Day 63, page 71. Comments on the study were made in the Preliminary Report at paragraphs 6.23 and 6.24.

**27.74** As discussed more fully in Chapter 15, *Knowledge of Viral Hepatitis 2 – 1975-1985*, the discussions in the Advisory Group on Testing for the Presence of Hepatitis B Surface Antigen and its Antibody led to an ad hoc meeting at the MRC on 12 February 1979 to consider the question of NANB Hepatitis.<sup>104</sup> The meeting concluded that a survey of post-transfusion hepatitis was not warranted.<sup>105</sup> Professor Cash commented that the decision was a serious blow to those BTS colleagues who believed that surrogate testing of blood donations in the UK should only be considered when appropriate prospective studies had been carried out. In Scotland, research showing that there was NANB Hepatitis infection in the blood donor population began to produce results only in the second half of 1979.<sup>106</sup>

**27.75** Following the meeting at the MRC in February 1979 a Working Party on Post-Transfusion Hepatitis was set up and met for the first time on 14 February 1980.<sup>107</sup> The Working Group was chaired by Dr Gunson.<sup>108</sup> Its functions included examining the position of research to characterise the agent(s) associated with NANB Hepatitis and to derive diagnostic tests.

**27.76** At that meeting, Dr McClelland advised that work was progressing at the South East Scotland Regional Transfusion Centre (RTC) into the problem of NANB Hepatitis associated with blood transfusion and suggested that a multi-centre study might be sponsored by the MRC into the problem of transfusion-associated NANB Hepatitis transmission. The minutes state: 'It was agreed, however, that this matter should be deferred until candidate laboratory tests were available'.<sup>109</sup>

**27.77** It was noted at the meeting that the following problems required investigation: (i) the identification of donors and units of blood associated with possible cases of NANB Hepatitis; (ii) research into methods of identifying the viruses associated with NANB Hepatitis and (iii) epidemiological surveys to assess the size of the problem in relation to blood transfusions. The minutes record that, following the ad hoc meeting at the MRC in February 1979, three special project grants had been supported for research into the incidence, epidemiology and clinical features of NANB Hepatitis and a fourth would probably soon be approved. It was noted that it was 'open to the Working Party to initiate fresh projects in this field'.<sup>110</sup>

**27.78** The second and, as it turned out, last, meeting of the MRC Working Party was on 25 June 1981.<sup>111</sup> At that meeting Dr McClelland tabled a protocol for a prospective study of post-transfusion hepatitis in the UK (to be carried out at Edinburgh and Manchester) based on the protocol used in the TTV study.<sup>112</sup>

**27.79** Dr McClelland had reported to a meeting of SNBTS Directors on 23 June 1981 that he had prepared the protocol for presentation to the MRC on 25 June for a two-centre study. The directors agreed that similar studies might be made in Scotland generally. Discussion noted at the meeting recorded that:

<sup>109</sup> Meeting minutes [PEN.017.1710] at 1711

<sup>110</sup> Ibid [PEN.017.1710] at 1711

<sup>111</sup> Meeting minutes [PEN.017.1478]

<sup>112</sup> Day 63, pages 71–72: Dr McClelland's proposed protocol is [PEN.017.1486]. In fact, Dr McClelland had corresponded with the TTV study group and obtained a copy of its protocol.

Dr McClelland offered to circulate to the Directors the text of a leading article in the *New England Journal of Medicine* of 23 April 1981 and (if the MRC permitted) the document which he had prepared for the MRC. Scottish Directors would not proceed with liver function tests on existing donations for the time being.<sup>113</sup>

**27.80** The objectives of Dr McClelland's proposed study included: (i) to establish the incidence and causes of transfusion-related hepatitis; (ii) to establish the incidence of elevated ALT in donors to evaluate the effectiveness of methods of donor screening; (iii) to establish a library of samples for future serological studies; (iv) to provide data for assessing the effectiveness of any new methods of donor screening and (v) to establish the long-term outcome of post-transfusion NANB Hepatitis by prolonged follow-up of all cases identified. Dr McClelland emphasised the desirability of obtaining accurate data concerning the incidence of transfusion-transmitted NANB Hepatitis in the UK.

**27.81** The minutes of the June 1981 meeting of the MRC Working Party note Dr McClelland's position when tabling his protocol:

Apart from the desirability of obtaining accurated [sic] data concerning the incidence of [NANB] transfusion hepatitis in the UK, it was also important to obtain information as to whether the screening of blood donors by the [ALT test] might be of value in the UK. It was also essential to obtain well documented specimens of serum from known cases of [NANB Hepatitis] for evaluation of any tests which might be of value for the diagnosis of this disease, and the screening of blood donors.<sup>114</sup>

**27.82** In oral evidence, Dr McClelland repeated his belief that it was essential to assess the importance of the NANB Hepatitis problem as a basis for the planning and evaluation of future donor screening strategies.<sup>115</sup>

**27.83** Dr McClelland's proposal had noted that there had been no prospective study in the UK of the incidence of sub-clinical hepatitis following transfusion of blood or single-donor blood products. That provoked a reaction from Professor Arie Zuckerman of the London School of Hygiene and Tropical Medicine.<sup>116</sup> The minutes note that Professor Zuckerman pointed out that a study had already been undertaken in the 1970s and that the sera from that study were available for the evaluation of any candidate tests for NANB Hepatitis.<sup>117</sup> A fresh study could cost from £50,000 to £100,000 to undertake. In Professor Zuckerman's view, a 'careful evaluation' of the need for such a project should be carried out before the Working Party could recommend to the MRC that a fresh study should be sponsored as 'the administrative difficulties encountered in the last project had been very hard to solve'. It was also noted that an evaluation of ALT screening of blood donors had been carried out at North West Thames RTC, Edgware, and that problems had been encountered as it had proved difficult to trace the fate of donors found to have raised ALT values.<sup>118</sup>

<sup>113</sup> Minutes of SNBTS Directors' Meeting, 23 June 1981 [SGF.001.0211] at 0215

<sup>114</sup> Minutes of MRC Working Party, 25 June 1981 [PEN.017.1478] at 1480. Professor Cash, who was a member of the MRC Blood Transfusion Research Committee, supported the proposed study. In his evidence to the Inquiry he stated: 'I believe we couldn't even think seriously about surrogate testing until we had done some important research, and much of that needed to be a replication in the UK context of the TTV study in the States. So I was very supportive': Day 64, pages 147–148. He also stated: 'I see no reason why a properly resourced and supported UK group could not have achieved parity of performance with the US TTV study group': Day 72, page 45

<sup>115</sup> Day 63, page 70; Dr McClelland's proposal for a prospective study of post transfusion hepatitis [PEN.017.1486]

<sup>116</sup> Day 63, page 70

<sup>117</sup> This is a reference to the MRC study which reported in 1974.

<sup>118</sup> Minutes of MRC Working Party 25 June 1981 [PEN.017.1478] at 1480

**27.84** In his evidence to the Inquiry, Dr McClelland explained that he had felt encouraged by the discussion at the meeting in February 1980 and particularly the reference to establishing fresh projects to produce proposals. Professor Zuckerman was very eminent, however, and his view, which carried particular weight, was that a study into post-transfusion hepatitis had already been carried out (the MRC study reported in 1974) and ‘it didn’t need to be done again’.<sup>119</sup> The Minutes record that Professor Zuckerman left the meeting before discussion of this topic was concluded. Dealing with the period after his departure, the minutes note that the Chairman, Dr Gunson, would write to Professor Zuckerman and to Professor Sheila Sherlock of the Royal Free Hospital, London, to see if the patient records and serum samples from the previous MRC study were still available and that ‘Dr McClelland’s project could then be reconsidered in the light of the specimens and clinical data available from the earlier study’.<sup>120</sup>

**27.85** In the event, the MRC Working Party did not meet again. The Working Party’s parent committee, the MRC Blood Transfusion Research Committee, was disbanded in July 1982, the MRC Board having concluded, in the light of activities of outside bodies and the proposal to set up a British Society of Blood Transfusion, that the committee’s work was being duplicated elsewhere.<sup>121</sup> This view was not shared by Professor John Cash, Medical Director of the SNBTS, who tried unsuccessfully to form a joint UK transfusion services’ research committee to fill what he saw as a gap.<sup>122</sup> He was concerned in particular because he knew as a council member of the recently formed British Blood Transfusion Society that the Society could not fund the studies advocated by the sub-committees of the MRC Blood Transfusion Research Committee.

**27.86** In addition, the sera from the earlier MRC study would turn out to have been destroyed. Dr McClelland, who was perplexed by the decision of the MRC Board,<sup>123</sup> persisted in his efforts to persuade colleagues of the need for a study. That position would be vindicated in 1987 by the Council of Europe’s Committee of Experts on Blood Transfusion and Immunohaematology, as described by Professor Leikola and discussed above, although Dr McClelland considered, and continues to believe, that it was by that time too late. It will be necessary to return to a discussion of that matter later. In the meantime, further research was ongoing.

**27.87** An editorial in *The Lancet* in July 1981 gave the flavour of the thinking at that time.

Despite 40 years’ efforts to find ways of preventing it, hepatitis still arises after transfusion of blood and blood products. The discovery of the hepatitis B virus and the development of increasingly sensitive tests for markers of hepatitis B infection was a major step forward, but a bigger contribution came from the recognition that paid blood donors, probably because of their lower socioeconomic status, were much more likely to transmit hepatitis than unpaid donors. In the United Kingdom, since the introduction of hepatitis B screening, transfusionists seem to have been mesmerised by this one virus and the thrust of hepatitis prevention has been towards introducing ever more sensitive tests for it, even though the evidence is that little additional protection is gained

<sup>122</sup> Letter from MRC to Dr Cash dated 19 July 1982 [SNB.002.5864]; Letter from Dr Cash to the SNBTS Directors dated 23 July 1982 [SGH.001.0087]; Report from Dr Cash to Blood Transfusion Service Sub-Committee dated 24 November 1982 [SNB.003.3603]

<sup>123</sup> Dr McClelland – Day 63, page 73

from tests more sensitive than the widely used haemagglutination assay. When non-A non-B hepatitis was first recognised, many British workers seemed to regard it as a purely American problem. Lately, non-A non-B hepatitis has been accepted in the U.K. as a serious hazard of treatment with factor VIII and factor IX concentrates, which are prepared from very large pools of donor plasma, but no-one has paid much attention to this type of hepatitis in the patient who receives a few units of blood or platelets. In a UK prospective study of post-transfusion hepatitis,<sup>124</sup> frank hepatitis developed in 1%, there were sustained increases of alanine aminotransaminase (ALT) in 4.5%, and the ALT was raised at some time after transfusion in 20%. Although only a small proportion of these cases of hepatitis and “transaminitis” seemed to be due to hepatitis B virus, nothing has been done to assess the value of preventive methods other than hepatitis B screening.

American workers have been less complacent.<sup>125</sup>

**27.88** The editorial traced some of the developments in the USA suggesting a need for careful examination and proceeded:

There are some other questions. How important in clinical terms is silent transaminitis after transfusion? Although regular users of blood products do get chronic liver disease which is probably due to non-A non-B agents, there is not much information about the long-term consequences of subclinical hepatitis after a single transfusion episode. In the U.K. there is no report about long-term follow-up of transaminitis patients from the earlier study. Furthermore, the value of ALT or other non-specific tests would have to be tested prospectively in various circumstances; after all, there are many reasons why the ALT may be raised, and in some communities a high proportion of blood donors might have to be rejected when the real reason for the abnormal result was alcohol.

If a new donor screening programme was set up, the high cost might be the least of the problems. Today, all transfusion services are aware of the plight of would-be donors who prove to be symptomless carriers of hepatitis B virus. Once these people are labelled as carriers, they may face difficulties in securing medical or dental care. We should be very much aware of the risks of creating a new and much larger group of donors who are rejected because of a new “hepatitis” test which does not necessarily signify infectivity, and which may be detecting a form of infection whose natural history we know very little about.<sup>126</sup>

**27.89** Indirectly, this provided eloquent support for Dr McClelland’s proposals.

**27.90** In July 1981 the need for research into post-transfusion NANB Hepatitis in the UK was raised by the Advisory Group on Testing for the Presence of HBsAg and its Antibody (also known as ‘the Maycock Group’ as it was chaired by Dr William Maycock) in its 3rd report.<sup>127</sup> While the Group’s remit dealt with testing for Hepatitis B, its report also

<sup>124</sup> Medical Research Council Working Party on Post-transfusion Hepatitis: Report to MRC Blood Transfusion Research Committee, *Journal of Hygiene*, 1974; 73:173-88 [LIT.001.0116]

<sup>125</sup> ‘Screening of blood donors for [NANB] hepatitis’, *The Lancet*, 11 July 1981:73 [LIT.001.0438]

<sup>126</sup> *Ibid* [LIT.001.0438]

<sup>127</sup> The third report of the Advisory Group, published in July 1981 [DHF.003.0037]

covered NANB Hepatitis. HBsAg screening of donations destined for fractionation was recommended, implying that all donations collected for transfusion purposes at RTCs would be tested for HBsAg.<sup>128</sup> Anti-HBs tests were recommended for as many new donors as possible to identify high titre donors to meet demand for the production of hepatitis B immunoglobulin. In relation to Anti-HBc, the report stated:

19. Blood donations which are negative for HBsAg by RIA and negative for anti-HBs, but positive for core antibody (anti-HBc) may occasionally transmit hepatitis B. Some of these donations are from donors recovering from unrecognised hepatitis B infections who still have minute but undetectable amounts of virus in their blood. At the present time there is no evidence that this type of donation causes more than a few cases of post-transfusion hepatitis (PTH) in the UK.

20. Screening all donations for anti-HBc would be costly and result in discarding many harmless donations from immune donors unless tests for anti-HBs were also carried out.

21. We recommend that there should be no general screening of donations for anti-HBc, but that all donors implicated in cases of PTH should be tested at reference centres for anti-HBc as well as for other hepatitis markers so that more information can be obtained on the dangers of HBsAg negative, anti-HBsAg negative, anti-HBc positive donors.<sup>129</sup>

**27.91** At this stage, the difficulty in assessing the frequency of post-transfusion NANB Hepatitis was, firstly, that there was no marker to show who had contracted it and, secondly, that most cases were asymptomatic. The Maycock Group's report noted further:

22. [NANB] hepatitis viruses are a common cause of PTH in the United States and are thought to have been responsible for cases of PTH in the UK.<sup>130</sup> Hepatitis due to these viruses is common among haemophiliacs and follows the administration of imported, and occasionally of British Factor VIII and Factor IX. There is evidence for the occurrence of sporadic cases of [NANB] hepatitis in the general adult population and in association with cryoprecipitate therapy in the UK.

23. There are at the present time no screening tests for detecting [NANB] hepatitis viruses in blood donations.

24. We recommend that research is undertaken in the UK to determine the extent and severity of PTH due to [NANB] hepatitis viruses. Unless this is done we will not have the knowledge on which to base any possible future recommendations about screening blood donations for these viruses. Regional Transfusion Directors should encourage hospital haematologists to report all cases of post-transfusion jaundice and where these could be due to [NANB] hepatitis, the facts should be reported to the appropriate Adviser in Blood Transfusion at the Department of Health and Social Security (DHSS) or Scottish Home and Health Department (SHHD).<sup>131</sup>

<sup>128</sup> Ibid [DHF.003.0037] at 0045

<sup>129</sup> Ibid [DHF.003.0037]

<sup>130</sup> NANB Hepatitis infection had been identified by Dr Follett in Glasgow by this stage.

<sup>131</sup> The third report of the Advisory Group, published in July 1981 [DHF.003.0037] at 0045-0046

**27.92** The same report dealt with 'Liver Function Tests':

25. Several categories of people are found to have raised blood transaminase levels which are not associated with viral hepatitis. Some 3% of new donors may be excluded if the criteria of one raised transaminase level is applied. In addition to the need for confirmatory transaminase testing the worry and inconvenience caused to donors would be unlikely to be compensated for by any clinical benefit. Therefore, we advise against these tests in screening blood donors at the present time but the subject should be kept under review.

26. Sporadic cases of apparent post-transfusion hepatitis due to the hepatitis B virus will continue to occur despite the most rigorous screening of donor blood samples because there are routes of infection other than transfusion; by coincidence, a transfusion may appear to have been responsible. Very few cases of PTH will continue to occur from donations with antigen below the present possible detection level. The donors involved may be in the early stage of incubating Hepatitis B.<sup>132</sup>

**27.93** Professor Cash was a member of the Maycock Group at this stage and the Group's third report was discussed at a meeting of the SNBTS Directors on 22 September 1981.<sup>133</sup> It was noted at the meeting that the transfusion services had various groups examining different topics but that hepatitis testing was not one of them. It was agreed that Professor Cash should write to Dr William Wagstaff<sup>134</sup> to propose that the UK transfusion services establish a post-transfusion hepatitis working group.

**27.94** Dr McClelland was by no means an isolated voice calling for research at this time, though it was to emerge that colleagues on relevant working parties, which may have held the key to organising and funding such studies, may not have shared his enthusiasm – as was to appear from the transactions of the next working party to be set up by the transfusion services: the Working Party on Transfusion Associated Hepatitis.

**27.95** The Working Party on Transfusion Associated Hepatitis met for the first time on 27 September 1982.<sup>135</sup> The Working Party comprised senior officials representing a range of transfusion interests in the UK. It was chaired by Dr Gunson, Regional Transfusion Director, Manchester, and its members were Dr John Barbara, North London, Dr Brian McClelland, Edinburgh, and Dr Mitchell, Glasgow, all RTDs, as well as Dr John Craske of the Public Health Laboratory, Dr Richard Lane of the Blood Products Laboratory, Dr Bruce Cuthbertson of the Protein Fractionation Centre (PFC),<sup>136</sup> Edinburgh, and Dr Howard Thomas of the Royal Free Hospital, London. The agreed Terms of Reference were:

To promote the investigations of the epidemiology of transfusion-associated hepatitis, to promote research into the methods of prevention, and to make recommendations to the Directors of the UK transfusion service regarding procedures and screening tests necessary for its prevention.<sup>137</sup>

<sup>135</sup> Minutes of Meeting [PEN.017.1716]. The members of the Working Party are listed at 1719

<sup>136</sup> The manufacturer of NHS blood products in Scotland

<sup>137</sup> Minutes of Meeting [PEN.017.1716]

**27.96** At the first meeting of the Working Party, the minutes record that Dr Gunson felt that existing reports provided an inadequate estimate of the true incidence of transfusion-associated hepatitis. It was agreed that a library of existing information on post-transfusion hepatitis would be collected for consideration at the next meeting, that Dr McClelland would produce an outline protocol for a prospective study of either the incidence of transaminitis (elevated liver enzymes such as ALT) in recipients or for determining the incidence of post-transfusion hepatitis in recipients of blood positive for existing putative markers of NANB Hepatitis, and that an attempt would be made to see if samples from the 1974 MRC study were still available.<sup>138</sup>

**27.97** In *A v The National Blood Authority* it was said that in 1982 Dr Gunson, in the name of the National Blood Transfusion Service (NBTS), applied for a grant to carry out a study in the UK into surrogate testing for NANB Hepatitis and that the application was refused. Documentary evidence of the grant application, or to whom the application may have been made, or its refusal, has not been found.<sup>139</sup>

**27.98** The Working Party met for the second time on 18 January 1983<sup>140</sup> and preparations for a study were discussed. The minutes note that '[i]t was agreed that some form of study was needed so that the UK is equipped to answer queries about any specific or non-specific tests for [NANB Hepatitis] offered from abroad'.<sup>141</sup> Dr McClelland circulated an outline proposal for a prospective study of NANB Hepatitis.<sup>142</sup> The outline proposal stated that a large scale prospective study of transfusion recipients and their respective donors, along the lines of the US TTV study, was not considered further because a similar study had previously been done in Britain<sup>143</sup> and samples were said to be available for reanalysis. It was further noted that a preliminary look at the financial implications indicated that a large scale multi-centre study would cost £250,000 to £500,000 and that, without further resources, Dr McClelland was not in a position to prepare even an initial outline of a study on that scale. Dr McClelland on this occasion appears instead to have suggested a more modest study 'to investigate the possible value of one or more putative markers of [NANB Hepatitis] in predicting the ability of a given blood donor to transmit the disease to a transfused recipient.'<sup>144</sup> Although the proposed study appears to have been smaller than the study Dr McClelland had proposed at the meeting of the MRC Working Party on Post-Transfusion Hepatitis on 25 June 1981, the study proposed on 18 January 1983 continued to include the follow-up of recipients. It was estimated that this proposed study would cost £63,000 and members of the Working Party were asked to provide Dr McClelland with their comments.

**27.99** The minutes of the meeting record that Dr Gunson would make a further attempt to ascertain from the MRC whether the samples from the MRC study reported in 1974 were still available and whether the recipients had been followed up to look for long-term effects. The minutes of the meeting noted that, '[i]f MRC samples are not available the working party will put forward proposals for some form of study to the MRC and DHSS'.<sup>145</sup>

<sup>143</sup> A reference to the MRC study, reported in 1974

<sup>144</sup> Dr McClelland's outline proposal [PEN.017.1514] at paragraph 1.2. Notwithstanding some uncertainty on the part of Dr McClelland (Day 63, pages 80–83) the study proposed appears to have been more modest in cost and scale than a large scale study, along the lines of the TTV study.

<sup>145</sup> Minutes of Working Party meeting, 18 January 1983 [PEN.017.1507] at 1512

**27.100** The Working Party met for the third time on 20 April 1983.<sup>146</sup> It was by then known that the samples from the 1974 MRC study had been destroyed.<sup>147</sup> Dr McClelland had been sent the results of a prospective study at Newcastle involving the follow-up of 248 patients.<sup>148</sup> As regards Dr McClelland's outline proposal for a prospective study of NANB Hepatitis, it was noted that '[s]o far a source of funding has not been found.'<sup>149</sup> It was thought that there would be a low incidence of post-transfusion NANB Hepatitis at Edinburgh. It was suggested that the North London RTC, Edgware, might provide a higher incidence area for the study. Dr John Barbara agreed to discuss matters with his Director at the Edgware centre and plans for a joint study with Edinburgh might then be submitted to the MRC by the Working Party.

**27.101** In his evidence to the Inquiry Dr McClelland commented on the attitude of the Working Party to a study into post-transfusion NANB Hepatitis in the UK involving the follow up of transfusion recipients:

Q: And what was the view of this working party of the need for a study of the type you proposed?

A: Well ... there was really very little enthusiasm. There was polite interest. But when it says ... [in] the minutes, "No source of funding has been found", no source of funding had been seriously sought. Nobody had gone back to the MRC, and I wasn't going to go back to the MRC at that stage myself as an individual because I knew I wouldn't get anywhere .... [I]t was perfectly clear there was going to have to be a major effort made to obtain major funding for this study.

....

Q: Obviously, you were of the view that there should be such a study?

A: I was strongly of the view but I was beginning to get a little bit worn down by that time actually because, you know, there is only a certain amount one can do as an individual and it wasn't lighting fires for anyone else.

Q: By anybody else, do you mean the other members of this working party or do you mean more widely?

A: Well, I mean other members of this working party because this was the first jumping-off point to get something done. If the working party had – looking at the membership of the working party, if those people had all put their shoulders behind this, something probably would have happened but that didn't happen.

Q: So you were largely driving forward this proposal by yourself?

A: I was endeavouring to, yes.<sup>150</sup>

---

<sup>146</sup> Minutes of Working Party meeting, 20 April 1983 [PEN.017.1522]

<sup>147</sup> Letter from the MRC to Dr Gunson [PEN.017.1507]

<sup>148</sup> As discussed below, the results of the Newcastle study were published later in 1983.

<sup>149</sup> Meeting minutes [PEN.017.1522] at 1523

<sup>150</sup> Day 63, pages 87–88

**27.102** Dr Ruthven Mitchell, Director of the Glasgow and West of Scotland RTC, was also a member of the Working Party. In his evidence to the Inquiry he explained his view of the difficulties in undertaking a large scale study of the type proposed by Dr McClelland. A large number of patients would require to be enrolled in the study to make it statistically valid, patients would require to be followed over a number of years and many patients who received transfusion would have died of their underlying condition (necessitating blood transfusion) before meaningful data on post-transfusion NANB Hepatitis might come to light.<sup>151</sup> Dr Mitchell's view was that a prospective study into post-transfusion hepatitis involving the follow-up of patients was '[a] very good idea in theory but not practical – very difficult to do practically'.<sup>152</sup>

**27.103** The Working Party met for the fourth time on 27 September 1983. While the subject of transfusion-associated hepatitis, including the question of carrying out prospective studies into the disease, appeared on the agenda for the meeting,<sup>153</sup> the minutes of the meeting contain no reference to any discussion of transfusion-associated hepatitis; instead, the discussion was dominated by AIDS.<sup>154</sup> In his evidence to the Inquiry Dr Mitchell was asked why there does not appear to have been a discussion of hepatitis at the meeting and stated, 'I think it was a preoccupation with another, much more lethal problem that we had [that is, HIV/AIDS]'.<sup>155</sup>

**27.104** As it turned out, the transfusion services' Working Party on Transfusion Associated Hepatitis did not meet again until it was reconvened in late 1986. The reasons for that are discussed below. Dr McClelland's view that there was very little enthusiasm in the Working Party for his proposals clearly understates what was at least tacit opposition from senior members of the group.

**27.105** As noted above, a team at Newcastle carried out a prospective study of post-transfusion hepatitis in cardiac surgery patients and reported in November 1983.<sup>156</sup> The study involved 248 patients who received a total of 1796 units of blood or blood components. All surviving patients were seen six months after surgery and were tested for ALT.<sup>157</sup>

**27.106** Six patients were found to have an increase in ALT levels which was unexplained and reached over 100 IU/L (normal < 40 IU/L). The authors considered that the incidence of 'acute short term incubation' post-transfusion NANB Hepatitis was therefore 2.4% (6/248). While these six patients had normal liver function six months after transfusion, a further two of the surviving 228 patients had raised ALT levels at six months. In one of these, liver biopsy disclosed chronic persistent hepatitis;<sup>158</sup> in the other, alcoholic liver disease was suspected. Overall, the authors considered that the incidence of 'significant chronic liver disease' after blood transfusion possibly attributable to an NANB Hepatitis agent was only 0.4% (ie 1/248). The paper concluded that '[NANB] hepatitis after blood

<sup>155</sup> Day 65, page 12

<sup>156</sup> Collins et al, 'Prospective study of post-transfusion hepatitis after cardiac surgery in a British centre', *British Medical Journal*, 1983; 287:1422 [LIT.001.0212]

<sup>157</sup> In addition, 44 patients who lived within a 10 mile radius of the hospital were tested every two weeks for two months and thereafter at monthly intervals for six months.

<sup>158</sup> Chronic persistent hepatitis was considered a generally mild, benign condition – see Chapter 14, *Knowledge of Viral Hepatitis 1*, paragraph 14.37.

transfusion from a largely British blood donor group probably leads to clinically significant chronic liver disease very rarely indeed'.<sup>159</sup>

**27.107** In oral evidence Dr McClelland said that the interpretation placed upon their data by the Newcastle group was consistent with the understanding of post-transfusion NANB Hepatitis at the time.<sup>160</sup>

**27.108** As noted already, *Vox Sanguinis* conducted a survey in 1983 of the opinions of various experts relating to the costs and benefits of routine donor screening for ALT. Dr McClelland expressed the following view in his contribution to the forum:

The only action which I would recommend at present is that there should be a thorough prospective study to determine the frequency with which post-transfusion hepatitis occurs in the regions served by this centre, or in a closely comparable population.

If the results of such a study indicate that post-transfusion hepatitis due to [NANB] viruses (PTH) occurs sufficiently frequently to cause concern, I would recommend further study be carried out to determine whether the introduction of a donor ALT screening programme does in fact reduce the attack rate for PTH. As an alternative it may well be possible to study simultaneously the attack rate for PTH in the recipients of ALT screened or nonscreened blood.

I consider that without undertaking thorough studies along these lines, the potential and actual scale of the 'benefit' side of the cost benefit calculation is unknown and therefore no rational decisions can be taken ....

I would therefore recommend that we are careful to establish the benefits *before* we become committed to the costs. We must know what improvement in the quality of our blood and blood products we are asking the community to pay for.<sup>161</sup>

**27.109** Dr Mitchell expressed the following view in the publication:

As ... ALT testing has obviously high false-positive and also high false-negative rates, we have no intention of suspending 3% of our volunteer blood donors on the basis of an ... ALT test when they may have only transient elevations. Furthermore, such a policy would discourage donor recruitment among the few willing to donate for the good of the community and would cause some anxiety in donors and their families when we cannot offer anything more than the argument that [NANB] hepatitis may exist. We have been most disturbed by the treatment or lack of treatment for unrelated diseases available to HBsAg positive blood donors and fear that donors with elevated ... ALT levels may suffer the same problems.

We await the development of a specific serological test for [NANB] hepatitis. The use of nonspecific tests such as ... ALT can have deep sociological and psychological effects on established blood donors and would necessitate the recruitment of voluntary nonremunerated replacements.<sup>162</sup>

**27.110** It is significant that within the Scottish service such strongly differing views should have been expressed by the Directors of the two major Regional Transfusion Centres. Faced with such a powerful statement by Dr Mitchell, Dr McClelland was most unlikely to make progress with his proposal.

### **1984–1985**

**27.111** The Inquiry has found little evidence to show that the issue of surrogate testing was considered in the UK in 1984 and 1985 or that consideration was given in these years to carrying out a UK study into the prevalence of post-transfusion NANB Hepatitis and its association with surrogate markers in donors. As noted above, for example, the transfusion services' Working Party on Transfusion Associated Hepatitis last met on 27 September 1983 (when discussion was dominated by AIDS) and did not meet again until, as discussed below, it was re-convened in late 1986.

**27.112** At a meeting called by the National Institute for Biological Standards Control (NIBSC), on 9 February 1984, Dr Terry Snape (BPL, Elstree, the manufacturer of NHS blood products for England and Wales) commented that screening for serum ALT had been considered in the USA but not used in the UK; this appears simply to have been a factual comment.<sup>163</sup> In the discussion that followed, there was no reference to its possible use in the UK. In the context of AIDS, testing for anti-HBc was discussed but there was no general agreement that the test should be part of the routine screening carried out on donors: its possible relevance to hepatitis was not mentioned.

**27.113** Dr Edward Follett and Dr Brian Dow,<sup>164</sup> reporting on a study of NANB Hepatitis in the West of Scotland in 1984, wrote:

Evidence from USA would suggest that if ALT/SGPT testing is performed on all blood donations and those with high levels excluded, around 29–40% of non-A, non-B PTH cases could be prevented with the loss of around 3% of blood donations.

A total of 10,655 West of Scotland blood donors have been tested for elevated SGPT(ALT) levels.<sup>165</sup>

**27.114** The table of results showed the concentration of ALT (measured in U/ml) in blood samples. Levels exceeding 35 U/ml were found in 367 individuals (3.4%), levels exceeding 92 U/ml in 55 individuals (0.51%) and those exceeding 125 U/ml in 41 individuals (0.38%). Prison session donors showed ten times more donations with grossly elevated ALT levels than others.<sup>166</sup>

**27.115** Drs Follett and Dow had shown that 'around 3% of blood donations' in the West of Scotland had elevated ALT values. Recipients of the donations were not followed up and no data were gathered on the use of the 10,655 donations or their destination within the blood services. Data were available of clinically likely cases of post-transfusion NANB Hepatitis reported to the Glasgow and West of Scotland BTS: there had been reports of nine cases only. The notification requirements related to 'infective jaundice'.<sup>167</sup> They

<sup>164</sup> Dr Follett worked at the Regional Virus Laboratory, Ruchill Hospital, Glasgow. Dr Dow worked in the Glasgow and West of Scotland BTS.

<sup>165</sup> Final Report to Scottish Hospital Endowments Research Trust [SGH.002.8040] at 8044–8045

<sup>166</sup> Ibid [SGH.002.8040] at 8045

<sup>167</sup> See Chapter 14, *Knowledge of Viral Hepatitis 1*, paragraph 14.12.

were not well adapted to generate reports of NANB Hepatitis which was, in fact, seldom associated with clinical jaundice. In addition, reports of notifications of an infectious disease whose characteristics were poorly understood by clinicians generally were most unlikely to provide sound evidence of prevalence of the condition. Without follow-up of the donations tested, the study did not provide a basis on which the prevalence of post-transfusion NANB Hepatitis could, or should, have been drawn. Unfortunately, it was concluded on the basis of the reported cases that post-transfusion NANB Hepatitis was 'not a major problem' in the region. That conclusion was not based on sound evidence. Nor did it indicate the potential value of ALT surrogate testing, or a basis for assessing that value.

**27.116** Even more unfortunately, as will be seen below, the conclusions from the report were for several years used to support the contention that post-transfusion NANB Hepatitis was not a significant problem.

**27.117** After an outbreak of post-transfusion NANB Hepatitis following the use of certain BPL immunoglobulin concentrates,<sup>168</sup> Professor Andrew Lever, Professor Howard Thomas<sup>169</sup> and others contrasted the lack of tests for the NANB Hepatitis virus(es) with tests for other viruses, at the end of 1984:

Sensitive radioimmunoassays for hepatitis B surface antigen and IgM anti-HB-core allow identification of cases of post-transfusion hepatitis caused by the hepatitis B virus, and similar assays exist for the diagnosis of hepatitis A, cytomegalovirus, and Epstein-Barr virus infections which are rarer causes. Most post-transfusion hepatitis, however, is caused by a group of unidentified viruses designated non-A, non-B.<sup>170</sup>

**27.118** As others had, they commented that a screening test was needed to identify NANB Hepatitis. However, by this time there had been no progress on that front and, in general terms, the 1984–85 period saw a low level of activity in post-transfusion hepatitis research.

**27.119** One significant reason for the relative lack of consideration given to post-transfusion NANB Hepatitis in this period was the priority given to tackling AIDS. In Dr McClelland's written evidence to the Inquiry, for example, he stated that, '[l]ooking back, I think it is the case that the work related to AIDS, firstly developing donor information and selection procedures and later evaluating and introducing the test for HIV antibody, distracted the attention of both the SNBTS and the [NBTS] from [NANB] hepatitis for about 3 years'.<sup>171</sup> A further reason for the apparent lack of consideration given to post-transfusion NANB Hepatitis in the UK at this time is likely to have been, as discussed above and below, that post-transfusion NANB Hepatitis was regarded as having a low prevalence in the UK (at least when compared with the USA) and that it was considered to be a relatively mild disease.

<sup>168</sup> It had been thought that Cohn fractionation either excluded or inactivated viruses from such preparations. That had not occurred in the instant cases.

<sup>169</sup> At that time, Professor Lever was an MRC Research Fellow in Immunological Medicine at the Clinical Research Centre, Harrow and Professor Thomas was Professor of Medicine at The Royal Free Hospital, London.

1986

**27.120** The SNBTS Directors continued to follow developments in the USA and so became aware of the FDA's 1986 recommendation on surrogate testing. A copy of the February 1986 edition of *Blood Bank Week* was circulated for the 25 March 1986 meeting of the SNBTS Directors.<sup>172</sup> Dr John Forrester, Senior Medical Officer, SHHD, attended the meeting and was noted in the minutes as stating that it was highly unlikely that the UK Departments of Health would fund testing based on data from the USA. Dr Forrester said that he would be glad to hear of research proposals but could not guarantee funding. The minutes record that, after a full discussion, the Directors agreed to give consideration to funding someone to undertake research. Professor Cash was to think about the possibilities in association with Dr Ian Fraser, Director, Bristol RTC,<sup>173</sup> and make proposals to the Directors.

**27.121** In the meantime, Professor Cash had made direct contact with the American Red Cross. He wrote to Dr Gerry Sandler of the American Red Cross Blood Services on 17 February 1986 to ask what had transpired at the meeting of the FDA Blood Products Advisory Committee with regard to surrogate testing for NANB Hepatitis and what the American Red Cross had decided.<sup>174</sup> Dr Sandler replied on 4 March advising on the position at that stage: there was a divergence of view and the Red Cross was not proceeding to test but would review the position.<sup>175</sup>

**27.122** Dr Forrester produced a note of the SNBTS Directors meeting for his SHHD medical colleagues, Dr Archibald McIntyre, Principal Medical Officer (PMO) and Dr Graham Scott, Deputy Chief Medical Officer (DCMO).<sup>176</sup> As regards testing of blood donations for NANB Hepatitis, Dr Forrester noted that in America it was proposed to reduce the transmission of 'this medley of conditions' by testing all blood donations for evidence of faulty liver function. Dr Forrester's note went on:

Since any additional test of this kind must necessarily be non-specific and could well prove expensive, I have as you know immediately made further enquiries, and have discovered that the number of cases in Scotland due to blood transfusion is probably exceedingly low, there is a solid body of work (a Ph.D. thesis)<sup>177</sup> exploring the matter, and I am securing Dr Dan Reid's opinion in writing in the near future. It was argued at the meeting that urgent action was called for rather than a search for reliable information, and that the case was comparable with that of AIDS. I pointed out however that the steps taken to deal with AIDS were taken in face of a rapidly rising incidence, while in the present case the incidence so far as I know is small and steady. There is thus no justification for panic measures. I also indicated that the Department was perfectly open to proposals for funding research in this field, if research is required to determine the true size of the problem and the likely effect of any proposed remedy.<sup>178</sup>

<sup>174</sup> Professor Cash's letter to Dr Sandler [SGF.001.2149]

<sup>175</sup> Dr Sandler's letter to Professor Cash [SGH.002.8189]; American Red Cross circular to regional blood services [SGH.002.8190]

<sup>176</sup> Note by Dr Forrester dated 26 March 1986, [SGH.002.7496]

<sup>177</sup> This is a reference to Dr Dow's 1985 PhD thesis, '[NANB] Hepatitis in West Scotland', discussed below.

<sup>178</sup> Note by Dr Forrester dated 26 March 1986 [SGH.002.7496] at 7497

**27.123** Dr Forrester wrote to Dr Reid on 26 March 1986 seeking information on the likely incidence of NANB Hepatitis in Scotland, the proportion attributable to blood transfusion and how far any proposed test could reduce this proportion.<sup>179</sup>

**27.124** Despite the views of the SNBTS Directors on the need for research into transfusion-associated hepatitis, there seems to have been little appetite among the Transfusion Directors in England and Wales for such research. At the meeting of the English and Welsh Directors on 24 and 25 April 1986 the question of whether a study into NANB Hepatitis should be carried out was raised. The minutes state:

The Chairman reported that this had been discussed by the Scottish Directors and that he had agreed to raise it with RTDs. [Name redacted] reminded Directors of two previous attempts, one by the MRC and one by the Transfusion Associated Hepatitis Working Party, to study this problem. After discussion it was agreed that this should not be pursued because of lack of time and resources.<sup>180</sup>

**27.125** Around May 1986, the SNBTS prepared its submission for the 1986 Public Expenditure Survey (PES).<sup>181</sup> This was an annual bidding process in which public bodies submitted applications for funding to the government. The Common Services Agency (CSA)<sup>182</sup> submitted the application for funding for all of the activities within its remit, including the SNBTS, to the SHHD. The administrative officials in the SHHD critically examined the funding application, taking advice from their medical colleagues on medical matters, before deciding on the items which should be forwarded to the SHHD's Finance Division. The Finance Division would then further examine funding applications before they were put to the relevant minister for approval, before ultimately being voted upon by Parliament.<sup>183</sup>

**27.126** In its 1986 bid, the SNBTS included a sum of £810,000 to commence new mass donation screening programmes in 1987–88, with a forward projection of £836,000 for 1988/89.<sup>184</sup> The fate of the funding request is discussed below. The reason for the funding request was set out in the 1986 PES, which was drafted by Professor Cash, as follows:

Despite the absence of specific tests to detect donations which transmit [NANB] hepatitis there is increasing evidence that both in Europe and North America formal moves will be made, within the next 12-18 months, to introduce surrogate testing of all donations (liver function and [anti-HBc] tests).<sup>185</sup>

---

<sup>179</sup> Letter [SGH.002.8187]. Dr Reid was Director of the Communicable Diseases Surveillance Unit, Ruchill Hospital, Glasgow. The Inquiry has, unfortunately, been unable to obtain a copy of Dr Reid's response to Dr Forrester which appears to have been dated 4 June 1986.

<sup>180</sup> Minutes of Meeting [DHF.002.1290] at 1296 (Item 16)

<sup>181</sup> SNBTS 1986 PES Programme Narrative [SNB.011.2637]

<sup>182</sup> Section 19 of the National Health Service (Scotland) Act 1972 provided for the constitution of the Common Services Agency for the Scottish Health Service with effect from 1 April 1974. Amongst its several responsibilities was the operational management of the blood services. See Chapter 17, *Blood and Blood Products Management*, paragraphs 17.23–17.25.

<sup>183</sup> Mr Macniven – Day 65, pages 148–159, 168–172; Mr Murray's statement [PEN.017.1755]. The PES set out the sums granted for the then current financial year (1 April to 31 March), the sums sought in the next financial year and, more speculatively, the sums sought for the following two years: Day 65, pages 164–165

<sup>184</sup> SNBTS 1986 PES Programme Narrative [SNB.011.2637] at 2640

<sup>185</sup> *Ibid* [SNB.011.2637] at 2649. Indeed, in a 'long-range' budget expenditure forecast prepared in 1982, Professor Cash had predicted that '[i]t is anticipated that technical developments will have reached a point within the next 5 years that the introduction of the testing of all donations for [NANB] hepatitis markers or associated markers will be mandatory.' SNBTS Forecast Development Estimates 1984–1986 – Introductory Comments by National Medical Director [SGH.001.8873] at 8878.

**27.127** In May 1986, Dr Dow, then a Senior Grade Scientific Officer in the Glasgow and West of Scotland RTC, produced a special report for the SNBTS Directors on 'Surrogate tests for non-A, non-B Hepatitis'.<sup>186</sup> Drawing on the work undertaken as part of his 1985 PhD thesis<sup>187</sup> and, in particular, looking at the extent to which reported cases of post-transfusion NANB Hepatitis in the West of Scotland were associated with surrogate markers in donor blood, Dr Dow was of the view that '[e]ven if the combination of anti-HBc and ALT tests were shown to be 100% effective the economics involved in conducting these tests would greatly outweigh the costs of hospitalization of the few reported NANB PTH cases'.<sup>188</sup> He concluded that:

The present UK policy of accepting donors with raised ALT levels (i.e. not routinely ALT testing), anti-HBc or histories of jaundice would appear to be correct. It would appear from the study that the introduction of such surrogate screening procedures would have little impact on reducing the already low level of NANB PTH cases at present reported within the West of Scotland region.<sup>189</sup>

**27.128** Dr Reid replied on 4 June 1986 to Dr Forrester's letter of 26 March.<sup>190</sup> He sent a copy of Dr Dow's thesis and, from Dr Forrester's note next referred to, appears not to have recommended surrogate testing. Dr Dow's thesis was then the only piece of work which related specifically to Scotland.

**27.129** On 12 June 1986 Dr Forrester produced a note, 'Transmission of [NANB] hepatitis by blood and blood products: is it practicable to reduce or prevent it by introducing ALT testing of donations?' Dr Forrester set out the outcome of his enquiries as follows:

1. The information in this note is mostly derived from the PhD thesis entitled "Non-A, Non-B Hepatitis in West Scotland", completed in 1985 by Dr BC Dow under the supervision of Dr Follett and others.
2. Hepatitis can be transmitted by blood and blood products, and is in Scotland an occasional but serious consequence of blood transfusion. In contrast, in USA as many as 10% of recipients may develop it. Established causes include Hepatitis B virus, Hepatitis A virus, Epstein-Barr virus and cytomegalovirus. Hepatitis B virus is now successfully excluded by testing of donations. Hepatitis A has caused little trouble because virus is only found in blood over a brief period.
3. [NANB] hepatitis is not a specific disease, but a heterogeneous collection of diseases. The hepatitis conditions due to the Epstein-Barr virus and cytomegalovirus are a substantial part of it, but there is general belief that some as yet unidentified virus infection is also part of it. Thus there can be no accepted test capable of detecting the virus in blood; detection is by exclusion of other conditions such as those mentioned.
4. [NANB] hepatitis, thus defined, is not uncommon in the population; Dr Dan Reid reckons an incidence for Scotland of 154 cases per year, but has little confidence in this estimate because it can only be derived by starting from

---

<sup>186</sup> Dr Dow's report [SNF.001.1109]

<sup>187</sup> Dr Dow's PhD thesis [LIT.001.3300]

<sup>188</sup> Dr Dow's report [SNF.001.1109] at 1110

<sup>189</sup> Ibid [SNF.001.1109] at 1111

<sup>190</sup> Preliminary Report, para 9.28. The Inquiry has, unfortunately, been unable to obtain a copy of Dr Reid's response to Dr Forrester.

the total of all hepatitis cases reported (probably under-reported) by clinicians, and deducting the cases of hepatitis B detected in laboratories (probably fully reported). It is common among drug-abusers. But in association with blood transfusion [NANB Hepatitis] is very uncommon in the west of Scotland. Over the last 8 years, 1-5 cases are found each year there, and there is no upward trend. There are peculiar difficulties in identifying its presence in haemophiliacs, since their blood exhibits diverse reactions because of repeated administration of blood products, but Dr Dow found no evidence of any substantial problem. Dr Dow reckons that the proportion of donations infected with [NANB] hepatitis may be 18 per hundred thousand [0.018%].

5. The condition is not as a rule serious, and most of the cases detected have not even been jaundiced. There may however be a tendency for it to become chronic, and the long-term outlook is inevitably not yet known. The case fatality rate is estimated in a textbook consulted by Dr Dan Reid at less than 0.1%, except in pregnant women, who are at much greater risk...

6. In the absence of a specific test, for some years the suggestion has been made that an enzyme test ("ALT") which detects faulty liver function should be applied to every donation. The advantage is that some donations might thus be excluded which would transmit [NANB] hepatitis. The drawbacks are that some infective donations might still be missed ("false negatives") and some harmless donations might be excluded ("false positives"). The American evidence is that both drawbacks are serious: only perhaps 38% of the genuinely infective donations are detected, and some 70% of the apparently infective donations are harmless. Rejection of donations might reach 3% – a grave loss.

7. ... Dr Dow concludes that in Scotland "cost would be extremely high and benefit minimal, especially when only a few cases of [NANB] post-transfusion hepatitis are reported each year."

8. Dr Dan Reid and Dr Follett do not recommend the introduction of ALT testing of Scottish blood donations, for the above reasons.<sup>191</sup>

**27.130** The issue of surrogate testing was considered by the SNBTS Directors at their meeting on 25 June 1986.<sup>192</sup> The minutes note that there was increasing evidence that the USA and several European countries were introducing surrogate testing of blood donors in an effort to minimise the risks of NANB Hepatitis transmission through blood and blood products. Professor Cash was noted as believing that the SNBTS would soon come under pressure from clinicians to introduce testing. A limited study involving the follow-up of donors (but not recipients) with abnormal liver function tests was about to take place in Edinburgh. Dr Fraser (Bristol) and Dr Contreras (Edgware) were keen to set up a small group to explore the feasibility and practicability of this development and hoped that a Scottish RTC would contribute. The Scottish Directors agreed to await the outcome of joint deliberations by Dr Fraser and Dr Contreras and to discuss the matter again at that time.

---

<sup>191</sup> Dr Forrester's note [SGH.002.8142]

<sup>192</sup> Minutes of SNBTS Directors' Meeting [SGH.001.6286] at 6290

**27.131** Further pressure was placed on the UK transfusion services by the recommendation in August 1986, noted above, from the AABB that all donor blood be tested for ALT and anti-HBc with effect from 30 November 1986, in an attempt to reduce NANB Hepatitis.<sup>193</sup> The positive response of the major blood delivery institutions in the USA, including the Red Cross, added to the pressure.

**27.132** Again, the SNBTS Directors were aware of developments in the USA. In a letter to Dr Fraser on 28 August 1986 on the question of surrogate testing, Professor Cash stated, 'I have a feeling that as the drums are beating louder and louder in other parts of the world on this topic the Brits remain fast asleep'.<sup>194</sup> While he noted that the suggestion of a UK prospective trial had been raised at the recent NBTs meeting and 'went down like the proverbial lead balloon', Professor Cash considered that the matter could not be left as it was. He proposed a meeting to look at the issues associated with donation testing, with a view 'to see whether we can reach conclusions which would enable us to make some clear operational decision[s] and that these would be transmitted to the various Departments of Health'.

**27.133** In his evidence to the Inquiry, Professor Cash stated that he did not support the introduction of surrogate testing at that stage but, instead, wanted more information upon which to base a decision. He explained that the benefit surrogate testing would bring to patients in the UK was unknown, the financial cost of testing would probably be taken from elsewhere in the NHS budget, the use of surrogate markers would cause uncertainty and concern among individual donors and blood collection would go down. He stated, '[t]his was making a major tactical moral position and we needed the data. So I supported ... getting the data very strongly'.<sup>195</sup>

**27.134** Dr Fraser replied to Professor Cash's letter and expressed the hope that if he, Professor Cash and Dr Contreras 'rowed hard enough' they could 'get our colleagues to move in the same direction'.<sup>196</sup>

**27.135** On 8 October 1986 the English and Welsh Transfusion Directors met.<sup>197</sup> In a discussion of surrogate testing the minutes noted:

The Chairman [Dr Fraser] reminded Directors that the possibility of screening for anti-HBc had been discussed previously .... Developments in America meant that this topic must be considered again as anti-HBc/ALT screening were soon to be essential for the accreditation of Blood Banks in the USA. The Chairman proposed that RTDs should approach the DHSS to fund a prospective study of 10,000 donations to see if the incidence of anti-HBc had changed since this was last examined. He added that Haemophilia Directors were pressing for plasma for fractionation to be tested both for anti-HBc and for abnormal ALT levels. It was agreed that a further trial should be undertaken at Edgware, Bristol and, possibly, Manchester and that an approach be made to Dr Smithies and Dr Moore<sup>198</sup> for assistance with this. It was recognised however that even if the incidence had reduced significantly since the last trial, because of self

<sup>198</sup> Both of the DHSS

exclusion or for other reasons, the introduction of anti-HBc/ALT screening seemed very likely.<sup>199</sup>

**27.136** It is interesting to contrast the position of the English and Welsh Transfusion Directors in April 1986, when there appeared to be little interest in undertaking a study into NANB Hepatitis,<sup>200</sup> with their position in October of the same year when, following the introduction of surrogate testing in the USA, they considered that the introduction of surrogate testing in the UK now seemed ‘very likely’. Dr Fraser was, in his own terms, ‘rowing hard’, having aligned himself with Professor Cash’s position.

**27.137** The SNBTS Directors met on 9 October 1986.<sup>201</sup> Dr Gunson was present and, in a discussion on surrogate testing, advised that three English centres (Edgware, Bristol and Manchester) were to study the incidence of raised ALT levels and anti-HBc in their donor populations. It was agreed by the Scottish Directors that the UK Working Party on Transfusion Associated Hepatitis<sup>202</sup> was the most appropriate body to pursue the issue of implementing surrogate testing in RTCs and that Professor Cash would write to Dr Gunson on behalf of the SNBTS Directors, formally requesting that this Working Party be reconvened with a view to making proposals to the Department of Health.<sup>203</sup>

**27.138** On 16 October 1986 Dr Scott, DCMO, sent a minute to Dr Forrester and Mr Alexander Murray, a Senior Executive Officer in the SHHD, on the question of NANB Hepatitis screening. Dr Scott’s minute stated:

I should like to know where this stands. CMO DHSS is worried that if we go ahead England and Wales will have to follow suit.

I think there must be consultation with DHSS before we agree to provide funds for this screening.<sup>204</sup>

**27.139** Dr Forrester replied on 17 October:

The recent situation is described in paragraph 5 of my note of the SNBTS Directors’ meeting of 9 October, which runs:

“Dr Cash is pressing the English BTS to seek a start of this, apparently on the grounds that UK are lagging behind “other parts of the world”. The initial – and very prudent – response is likely to be a call for research. Some has already been done last year in Scotland,<sup>205</sup> but turned out discouraging to Dr Cash’s purposes; certainly he never mentions it. Dr Gunson of English BTS believes that “external pressures” will compel a start of Surrogate testing. One may guess that this testing would cost the UK about £8m.”

<sup>201</sup> Minutes of SNBTS Directors’ Meeting, 9 October 1986 [SGF.001.0268]

<sup>202</sup> Which, as discussed above, paragraph 27.104, had last met on 27 September 1983

<sup>203</sup> Minutes of SNBTS Directors’ Meeting, 9 October 1986 [SGF.001.0268] at 0272

<sup>204</sup> Letter dated 16 October 1986 from Dr Scott to Dr Forrester and Mr Murray [SGH.002.8146]. In his evidence to the Inquiry, Dr Iain Macdonald, Chief Medical Officer, stated that, for his part, he would have had in mind ‘agreement’ with the DHSS rather than ‘consultation’: Dr Macdonald – Day 66, pages 105–106. The relationship between the DHSS and the SHHD is discussed more fully below.

<sup>205</sup> A reference to the Dow/Follett research project in the West of Scotland

There seems no justification for introducing this screening without gathering further British evidence, because the American experience of frequent post-transfusion hepatitis does not seem to be duplicated here.<sup>206</sup>

**27.140** Also on 17 October 1986 Dr Forrester wrote to Dr Alison Smithies, DHSS,<sup>207</sup> enclosing a copy of his note of 12 June 1986,<sup>208</sup> a letter dated 4 June 1986 from Dr Reid of the Communicable Diseases Centre,<sup>209</sup> the special report on surrogate testing compiled by Dr Dow for the SNBTS Directors in May 1986<sup>210</sup> and the 1983 discussion in *Vox Sanguinis*.<sup>211</sup> Dr Forrester ended his letter:

I have no reason to think that Scotland is imminently about to adopt Surrogate testing. I hope that the message south and north of the Tweed will be “research first, action later.”<sup>212</sup>

**27.141** On 21 October 1986 Mr Murray responded to Dr Scott’s minute of 16 October.<sup>213</sup> In his response Mr Murray stated that ‘the bid we are making to our Finance colleagues for money for the SNBTS in 1987/88 makes no provision for [NANB] Hepatitis screening’.<sup>214</sup>

**27.142** In his written evidence to the Inquiry, Mr Murray stated that ‘[i]t was technically my call not to include funding for screening in the overall bid as I was the person responsible for drafting and submitting the bid to Finance Division, but I made my call based on advice from my medical colleagues’.<sup>215</sup> It is apparent that the decision was, in substance, treated as a matter for the medical officers of the SHHD. The timing of the decision reflected in Mr Murray’s minute is significant. In particular, it was before the sequence of events described in the following paragraphs.

**27.143** As a result of the suggestion by the SNBTS Directors at their meeting in October 1986 that the issue of surrogate testing should be pursued by the UK transfusion services’ Working Party on Transfusion Associated Hepatitis, that Working Party was re-convened with a view, amongst other matters, to making proposals to the DoH (see paragraph 27.137 above).<sup>216</sup>

**27.144** In advance of the meeting of the re-convened Working Party, Dr Gunson circulated a report dated October 1986 on ALT and anti-HBc screening of blood donations.<sup>217</sup> In his report, Dr Gunson stated that the best estimate of the incidence of transfusion-associated NANB Hepatitis in the UK was 3%. If it was assumed that the 2.3 million donations in the UK were transfused to 750,000 recipients annually then one would expect 22,000 icteric or anicteric cases of NANB Hepatitis (cases, that is, with or without clinical jaundice) in each year. If the morbidity pattern of the disease was similar to that in the USA then one

<sup>213</sup> Minute dated 21 October 1986 from Mr Murray to Dr Scott [SGH.002.8140]

<sup>214</sup> A reference to the SNBTS 1986 PES, discussed above, in which the sum of £810,000 had been sought with a view to surrogate testing being introduced in 1987/88

<sup>215</sup> Mr Murray’s written statement, [PEN.017.1755] at 1758. Mr Macniven accepted, however, that, as Mr Murray’s superior, he would require to have approved the bid to the Finance Division: Mr Macniven – Day 65, pages 157–158

<sup>216</sup> The Working Party had last met on 27 September 1983

<sup>217</sup> Report by Dr Gunson dated October 1986 [PEN.017.0806]

might expect half of these patients to have chronic ALT elevation and 10% (that is, 2250) to develop cirrhosis. As regards the projected value of ALT and anti-HBc screening in preventing transfusion-related NANB Hepatitis, the report stated that if 30–40% of NANB Hepatitis could be prevented by the use of these tests then the reduction in the number of cases would be 6750–9000 a year and, by extrapolation, 675–900 cases of cirrhosis. The argument followed the approach of Dr Alter's group in February 1986 when it changed direction and supported surrogate screening.<sup>218</sup>

**27.145** The report went on to say, however, that qualifications required to be made to these estimates. In summary, these were:

(i) The course of the chronic disease in NANB hepatitis was thought to be mild and it was therefore thought that many cases probably remained undiagnosed, even when cirrhotic changes occurred. Dr Gunson felt certain that was why they had not been aware of what appeared to be quite serious statistics. It was also necessary to bear in mind that approximately 50% of patients died of their primary disease within one year of transfusion.

(ii) The incidence of NANB Hepatitis had been determined in the USA, often with multiply-transfused patients and in the TTV study there was clearly a dose relationship. Even in the second of the two UK studies the patients (6) received an average of 6.28 units each.

(iii) The data from the USA was from transfusions administered in the 1970s and early 1980s and even the more recent studies in the UK were undertaken before attempts to encourage the self-selection of donors.

(iv) It had to be questioned, therefore, whether the incidence of transfusion-associated NANB Hepatitis was as high as the estimates suggested.<sup>219</sup>

**27.146** As regards the likely effect of surrogate screening on blood collection, Dr Gunson's report estimated that ALT screening might cause the loss of 0.7–0.9% of donations, anti-HBc might cause the loss of 1% of donations and, assuming some overlap between these two groups, one might expect a loss of donations of approximately 1.5–1.75%. Since the data were largely from the time period before self-exclusion of donors for HIV infection, it was considered 'important to determine in a new study, preferably carried out in three Centres in England ... how many donations are rejected. Preferably, also one Centre in Scotland should join the study .... [A]nalysis of the results should yield information from which a prediction of loss of donations throughout at least England and Wales, can be estimated'.<sup>220</sup> Other topics for discussion mentioned in the report were the costs of implementing ALT and anti-HBc screening, the effect of screened donations in lessening the occurrence of NANB Hepatitis from fractionated products derived from pooled plasma and how donors would be managed if routine screening was introduced.

**27.147** Dr Gunson's report was considered on 24 November 1986 at the meeting of the re-convened UK Working Party on Transfusion Associated Hepatitis. The Inquiry has not been able to recover the minutes of the meeting. The Inquiry does, however, have a copy of Dr McClelland's handwritten notes of the meeting<sup>221</sup> and a note of the meeting prepared

<sup>218</sup> See paragraphs 27.49–27.50

<sup>219</sup> Report by Dr Gunson dated October 1986 [PEN.017.0806] at 0809

<sup>220</sup> Ibid [PEN.017.0806] at 0810

<sup>221</sup> Or, at least, part of the meeting as Dr McClelland was late in attending the meeting as a result of transport delays: Dr McClelland's note [PEN.017.1540]

by Dr Forrester on 1 December 1986.<sup>222</sup> Dr Forrester's note, expressing his personal view and intended for his SHHD colleagues, states:

1. Is the American experience of frequent [NANB] hepatitis in recipients of blood and blood products reproduced here? If so, a 40% reduction in it would follow screening. The answer is No. Such evidence as exists does not bear out the American experience, but to examine the question properly would be a long and expensive business ....

2. ... Dr McClelland put the proportion of local donations showing an ALT test in excess of 45 i.u. (a credible place for the line) at ... 3.4%. The proportion excluded by [anti-HBc] screening is put at 1 to 1.8% .... It is clear that much "innocent" blood would be excluded.

....

4. Is research indicated? The meeting felt that a prospective study to discover the present burden of transfusion-associated [NANB] hepatitis was impracticable on grounds of cost and huge sample size. They propose instead a study to identify in three centres (1 Scottish) donors positive for ALT or core antibodies, and search for other risk factors in them ....

5. There was some discussion of the cost of screening all donations (perhaps £8m). I asked the Chairman [Dr Gunson] whether he would advise screening if it were free of cost. He said No.<sup>223</sup>

The position explicitly reached at the meeting is to recommend research of no great significance or scientific interest because the prospect of research would serve to counter pressure from for example haemophiliacs and Haemophilia Directors to embark on an indirect and largely ineffective form of screening, which would also lose us a certain amount of perfectly harmless blood. Figures were produced at the meeting for the total number of [NANB] hepatitis cases encountered annually among haemophiliacs (A and B) and patients with von Willebrand's disease. The average UK total per year is 35 over the past 6 years, but 1985 saw a sharp decline to 11 in all. A proportion of these cases among haemophiliacs and similar patients are asymptomatic.<sup>224</sup>

**27.148** It is difficult to reconcile Dr Forrester's note of the total number of NANB Hepatitis cases encountered annually among patients with haemophilia, with UK reports from the early 1980s showing that most haemophilia patients who received Factor VIII and Factor IX blood products for the first time, whether manufactured by the NHS or by commercial companies, were likely to develop NANB Hepatitis.<sup>225</sup> In his evidence to the Inquiry Dr McClelland thought that what was reported by Dr Forrester in this regard must have

---

<sup>222</sup> Dr Forrester's note [PEN.017.1554]

<sup>223</sup> In closing submissions to the Inquiry it was suggested that this must be an inaccurate reporting of Dr Gunson's position [PEN.019.0605] at 0620. That does not, however, appear to be the case. As noted below, Professor Cash's view at the time was that given the difficulties with surrogate testing and the uncertainties about the benefits it would bring, his position in late 1986 would also have been that he would not have recommended the introduction of surrogate screening even if it were free of cost.

<sup>224</sup> Dr Forrester's note [PEN.017.1554]

<sup>225</sup> Fletcher et al, '[NANB] hepatitis after transfusion of factor VIII in infrequently treated patients', *British Medical Journal*, 1983; 287:1754 [LIT.001.0239]; Kernoff et al, 'High risk of [NANB] hepatitis after a first exposure to volunteer or commercial clotting factor concentrates: effects of prophylactic immune serum globulin', *British Journal of Haematology*, 1985; 60:469 [LIT.001.0800]. This is discussed further in Chapter 15, *Knowledge of Hepatitis 1975 to 1985*, paragraph 15.95

been a misunderstanding of what was said at the meeting.<sup>226</sup> Whether or not that is the case, Dr Forrester's note contains the information circulated to SHHD colleagues, including the inaccurate assessment of the prevalence of NANB Hepatitis infection among haemophilia patients before effective viral inactivation was introduced. Dr McClelland also cast doubt on the accuracy of Dr Forrester's description of the meeting, indicating that the suggestion that they would 'do some research to shut people up', would be untypical and uncharacteristic of the sort of discussion that took place at such meetings. Dr Alison Smithies, a member of the Secretariat to the Working Party, also expressed surprise at the suggestion that the position explicitly reached at the meeting was to recommend research which was of 'no great significance or scientific interest' in order to 'counter pressure' for the introduction of surrogate screening. She, too, considered that such a position would have been uncharacteristic of the discussions of the Working Party and refuted the suggestion that the study was put forward for any reason other than to clarify the likely consequences of introducing surrogate screening and to provide information which would allow the number of lost donations to be estimated.

**27.149** As indicated above (paragraph 27.141), a decision had already been taken before this meeting that provision would not be made in the PES bid for funding the SNBTS for screening in 1987/88. It appears that opposition to screening within the SHHD, at least on the part of Dr Forrester, became more deeply entrenched at the meeting.

**1987**

### Product liability

**27.150** In 1985, a European Directive was adopted which provided for strict liability for harm caused by defective products.<sup>227</sup> Member states were required to implement the Directive in their national legal systems by July 1988. In the UK, the Department of Trade and Industry (DTI) was the lead department responsible for implementing the Directive. The Consumer Protection Bill was drafted to give effect to the Directive and, in due course, the Bill became the Consumer Protection Act 1987. The part of the Act providing for strict civil liability for harm caused by defective products came into force on 1 March 1988.<sup>228</sup>

**27.151** During 1986 Professor Cash had expressed concerns about the implications of the proposed legislation<sup>229</sup> and had made representations for blood and blood products to be removed from the ambit of the legislation with a view to preventing the transfusion services and, possibly, blood donors being held strictly liable for harm caused to patients by treatment with blood and blood products.

**27.152** Dr Graham Calder, Chief Pharmaceutical Officer, SHHD, raised Professor Cash's concerns with the DTI who, by letter dated 9 February 1987, advised that they were not persuaded that there was any justification for removing blood and blood products from the provisions of the legislation.<sup>230</sup>

<sup>226</sup> Day 63, page 120

<sup>227</sup> Council Directive 85/374/EEC of 25 July 1985 on the approximation of the laws, regulations and administrative provisions of the Member States concerning liability for defective products

<sup>228</sup> Section 2 of the Act provides that, subject to certain defences, the producer of a product was liable, without evidence of fault, for damage caused wholly or partly by a defect in the product. Part I of the Act came into force on 1 March 1988 by virtue of The Consumer Protection Act 1987 (Commencement No.1) Order 1987, No. 1680: [PEN.017.2557]

<sup>229</sup> See, for example, the note dated 30 June 1986 by Dr Forrester of the meeting of the SNBTS Directors on 25 June 1986 at which Professor Cash had continued to express 'grave anxiety' in respect of product liability. [SGH.001.6295] at 6296

<sup>230</sup> Letter [SGH.005.0155]

**27.153** By a minute dated 13 February 1987, Mr Calder advised Dr Scott, DCMO, and the SHHD administrative officials of the DTI's response.<sup>231</sup> By letter dated 13 March 1987, Mr Hugh Morison, Under Secretary, SHHD, wrote to Mr Jim Donald, General Manager, CSA, advising him of the decision by the DTI that blood and blood products would remain within the provisions of the Act.<sup>232</sup> Mr Morison sent a copy of that letter to Professor Cash.<sup>233</sup>

**27.154** The risk of product liability became a new and material factor influencing policy.

### Surrogate screening

**27.155** The reconvened UK BTS Working Party on Transfusion Associated Hepatitis met for the second time on 22 January 1987. Dr Forrester was present and wrote a note of the meeting.<sup>234</sup> Those present were still not happy about proceeding with ALT screening and anti-HBc tests without further research to ascertain the infectivity of the donations and the meaning of the presence of anti HBc. There was discussion on the proposal for research into ALT and anti-HBc screening. It was hoped that the research might start on 1 April, subject to funding.

**27.156** On 26 January 1987, Dr Forrester produced a note, 'Material for PMO Report'. He made the following comments on blood transfusion and NANB Hepatitis:

This "hepatitis" is a residual rag-bag when Hepatitis B and Hepatitis A are excluded, and consequently no specific test can detect it. It is relatively benign. But U.S. blood banks have noted that the combination of a liver function test and a test for the core (not the surface) antigen of Hepatitis B distinguishes perhaps a third of blood donations which would convey [NANB Hepatitis] and allows them to be excluded. Exclusion is far from complete, and besides, some 2% of "innocent" donations may also be excluded.

....

Here, it is intended instead to enquire into the number of relevant donations and the characteristics of the donors, before taking any further step.<sup>235</sup>

**27.157** Dr Forrester's unqualified statement that NANB Hepatitis was 'relatively benign' would have been difficult to sustain in the light of research published by the end of January 1987. (See Chapter 16, *Knowledge of Hepatitis 3 – 1986 Onwards*, paragraphs 16.5 and 16.6.)

**27.158** The SNBTS and Haemophilia Centre Directors met on 9 February 1987.<sup>236</sup> Dr Forrester reported on the recent meeting of the Working Party on Transfusion Associated Hepatitis and the proposal to set up a UK study based on four centres, one of which would be in Scotland. The purpose of the study would be to discover the number of donations affected, what a positive test result meant about the donor, the effect of giving

<sup>231</sup> Minute [SGH.005.0149]

<sup>232</sup> Letter [SGH.005.0140]

<sup>233</sup> At a meeting on 31 March 1987 between Mr Macniven, Dr McIntyre, Dr Forrester, Mr Donald and Professor Cash, at which various blood transfusion issues were discussed, Professor Cash once again made representations, unsuccessfully, that product liability should not extend to blood products – Note of meeting [SNB.009.0041] at 0043 (item 11). Detailed guidance was not issued on how the Act impacted on blood transfusion practice. See letter dated 5 April 1988 [SGH.005.0054] and reply dated 25 April 1988 [SGH.005.0049]

<sup>234</sup> Note of meeting [SGF.001.2102]

<sup>235</sup> Dr Forrester's note [SGH.003.1657]

<sup>236</sup> Minutes of SNBTS and Haemophilia Directors' meeting, 9 February 1987 [SGF.001.2261]

blood positive on this screening and the cost of screening. Professor Cash noted that commercial products, if derived from screened plasma, might enjoy an advantage over products derived from unscreened plasma. The Haemophilia Directors indicated that they would not elect for commercial products on that basis. Their preference was to be supplied with heat-treated products. The cost of screening in Scotland was estimated to be approximately £750,000 per annum.<sup>237</sup>

**27.159** On 10 February 1987, having received a letter from Dr Susan Lader (Medical Officer, DHSS) on the proposal for a multi-centre study of ALT and anti-HBc in blood donations,<sup>238</sup> Dr Forrester wrote a memorandum to Dr Boyd Moir, Director of the SHHD's Chief Scientist Office on Scottish participation in the research project.<sup>239</sup> The SNBTS had sought approximately £600,000 to institute screening and conduct it for a year. That request was declined. Dr Forrester noted that joint consideration by the SNBTS, SHHD, DHSS and the English transfusion service indicated that 'instead of blindly adopting American practice, research should be conducted' and that 'a project involving 3 English and 1 Scottish transfusion centres' was being planned. Funding for the Scottish component of the research was sought from the CSO, to be determined in cooperation with the Research Management Division, DHSS. Dr Moir replied in a memorandum dated 17 February 1987.<sup>240</sup> He had very strong reservations about funding a research project including a Scottish transfusion centre, stating that the proposal would appear to 'merely repeat a study we have already carried out' over a three year period by Drs Follett and Dow, reported two years earlier and funded by the CSO. If the SNBTS wished to formulate a research proposal for funding from the CSO it should be submitted as an application for formal review by the Biomedical Research Committee.

### **SNBTS Directors meeting on 3 March 1987**

**27.160** The SNBTS Directors met on 3 March 1987.<sup>241</sup> The minutes of the meeting record the discussion of surrogate testing. It was reported that the UK Working Party on Transfusion Associated Hepatitis had been reconvened to pursue the issue of implementing surrogate testing for NANB Hepatitis. The proposal for a study which would include the Glasgow or Edinburgh Transfusion Centres had been modified and no Scottish Centre was now being asked to participate. It was noted that the Haemophilia Society might adopt a position which put pressure on BPL to ensure surrogate testing was introduced. The Directors discussed the options open to Scotland and agreed to recommend to the SHHD that surrogate testing for NANB Hepatitis should be implemented with effect from 1 April 1988 as a national development requiring strictly new funding. The individual Directors were to let Professor Cash know what funds would be required in each region, assuming that both anti-HBc and ALT testing would be undertaken in the regional transfusion centres.

**27.161** In oral evidence Professor Cash explained that by early 1987 surrogate testing had commenced in the USA and he was aware that his colleagues in Europe were considering the issue. He said:

I began to get the jitters that once again in the UK we had gone to sleep, we were off the ball, and I felt that I had a duty as national director to advise my colleagues that we should get in an application for money in the event –

---

<sup>237</sup> Ibid [SGF.001.2261] at 2263–2264

<sup>238</sup> The Inquiry does not have this letter

<sup>239</sup> Minute from Dr Forrester to Dr Moir, dated 10 February 1987 [SGF.001.2100]

<sup>240</sup> Minute [SGH.002.8123]

<sup>241</sup> Minutes of SNBTS Directors' meeting [SGH.001.6653] at 6657–6658

knowing that in the event of the Department of Health saying, “Yes, okay, go,” at least the budget was there to get down to the detailed difficulties of doing it.<sup>242</sup>

**27.162** He was asked what the reasons were for the Directors’ recommendation that surrogate testing should be introduced and replied that ‘[t]he reasons were that the rest of the world seemed to be walking in that direction ... and associated ... the product liability and the whole question of patient safety’.<sup>243</sup> Professor Cash was asked how it was envisaged that the recommendation would be taken forward and replied that the attendance of an SHHD official (in this case, Dr Forrester) at the Directors meeting was one means. He went on:

The other method, which was in parallel, was going through our PES submissions ... that would go into the department and we thought that would generate discussion and debate and so on and so forth, and we would get the thing going.

What we were concerned about is that we didn’t seem to be able to get it going in the ... post-transfusion hepatitis working parties<sup>244</sup> ... Harold [Gunson] was alerting to us in interactions with the DHSS. What we were doing was saying, “We have a responsibility here. Let’s lead off and get the debate going,” and the way we can get this going that we felt most comfortable with was a suggestion that we need some money to do that and that would, we felt, trigger off debate.<sup>245</sup>

**27.163** It was put to Professor Cash that if the SNBTS was serious about the recommendation to introduce surrogate testing then the SNBTS should have formally made the case by some form of detailed, reasoned, submission to the SHHD. Professor Cash said that the case he and his colleagues were trying to make was weak because of the lack of data on patients.<sup>246</sup> Consequently, they required to rely on the fact that other countries appeared to be moving towards such testing and that the UK licensing authority now recognised that ALT testing improved product safety. He was, simply, trying to draw their attention towards testing that he perceived as existing elsewhere.

**27.164** In his oral evidence Dr McClelland stated that he had no recollection of the meeting of the Directors on 3 March 1987 but was surprised on recently reading the minutes to see the clarity of the recommendation that surrogate screening should be implemented. He considered that it must have been primarily motivated by the awareness of what was going on in the USA. His recollection was that there wasn’t much enthusiasm among the other Scottish Directors for the introduction of surrogate testing.<sup>247</sup> In a memorandum dated 18 May 1987, Dr Forrester recorded his astonishment that Dr McClelland had agreed to the proposal, although he had heard Dr McClelland say on other occasions that he viewed the institution of screening as inevitable.<sup>248</sup>

---

<sup>242</sup> Day 70, page 175

<sup>243</sup> Ibid

<sup>244</sup> Professor Cash also stated: ‘we reached a point where it was evident to me, and I think Brian McClelland, that that working party yet again – it was nobody’s fault, was not going to go anywhere.’ Day 70, page 179

<sup>245</sup> Day 70, page 176

<sup>246</sup> Ibid pages 177–178

<sup>247</sup> Day 63, pages 122–124.

<sup>248</sup> Dr Forrester’s memorandum [SGH.002.8117]

**27.165** In his oral evidence, Dr Mitchell stated that if American blood banks and fractionators introduced surrogate testing then the UK might have been 'forced' to do the same thing. Impending product liability legislation was also a factor. He was very doubtful, however, whether surrogate testing would have materially increased patient safety, in particular against the background of very few reports in his region of patients developing post-transfusion hepatitis.<sup>249</sup>

**27.166** In his written evidence to the Inquiry Dr Macdonald, CMO, referred to:

[T]he increasing pressure perceived by SNBTS from about mid-1986 to introduce surrogate testing. A major source of this pressure was that moves were afoot elsewhere in the world, including particularly among commercial producers in USA, to introduce surrogate testing. The existence of these commercial producers cast a long shadow over fractionation activities within the NHS.<sup>250</sup>

**27.167** During his oral evidence Dr Macdonald was asked what he meant by the reference to commercial producers casting 'a long shadow' over fractionation activities within the NHS and explained:

I think this was a very peculiar situation, in which the NHS was itself a producer and in that sense it was in competition with commercial producers, in a way that I don't think was replicated anywhere else in the service. I think what struck me at the time, when I wrote that ... [was] that commercial producers, particularly in the United States, were beginning to introduce surrogate testing. In the way in which commercial operators work, they would be presenting this in the publicity in their advertising as an advantage. My stuff is better than your stuff. I wouldn't be sure that that was altogether fair but we, really, I don't think I felt that we could quite adopt these standards.

So there was a lack of balance.<sup>251</sup>

**27.168** Professor Cash stated that the SNBTS was concerned that the UK Medicines Licensing Authority was being persuaded that the introduction of surrogate testing of the plasma feed-stock of commercial fractionators would further enhance the safety of their products and that this unproven claim could be included in package inserts and marketing materials. He noted that the SNBTS view was that it had a moral obligation to patients in Scotland, Scottish based Haemophilia Directors and tax payers who had invested in the PFC, to seek funding to enable the SNBTS to follow this lead. Consequently, the PES proposal that they put to the SHHD was not 'directed to routine blood transfusions but to large pooled high risk PFC products'.

**27.169** Dr Macdonald agreed with the suggestion that the Directors' recommendation to introduce surrogate testing came as something of a surprise and, in particular, that it was such a firm recommendation, although there was an awareness that it was coming. He would have expected the interests of donors to have been given more attention.<sup>252</sup>

---

<sup>249</sup> Day 65, pages 18–24, 32 and 59–63

<sup>250</sup> Dr Macdonald's supplementary statement on surrogate testing [PEN.017.2048] at 2051

<sup>251</sup> Day 66, pages 90–91

<sup>252</sup> Ibid pages 128 and 143

**27.170** Dr Macdonald was also asked about the working relationship between the SNBTS and the SHHD at the time and replied that it was 'a little difficult'.<sup>253</sup> He stated:

What I learned, I suppose mostly from casual conversations with colleagues like Dr Scott and Dr McIntyre – I think they had some difficulty in understanding, at times, just where the regional directors stood and would be a little uncertain if the position that they seemed to be taking was the position they were going to hold. I'm not referring specifically to this surrogate testing issue, but I think there was an uneasy relationship.<sup>254</sup>

**27.171** As noted below, there were different views in the SNBTS on whether surrogate testing should be introduced. In his evidence to the Inquiry Dr McClelland said that that did not worry him very much because 'I felt it was a matter that was highly controversial and there was nothing particularly wrong with having a lively debate in the organisation. Not everybody felt that way about it'.<sup>255</sup> In a subsequent letter to Professor Cash, responding to a draft paper by Dr Gillon in which Dr Gillon had expressed the view that surrogate testing should not be introduced without further research, Dr McClelland acknowledged that there was undoubtedly a problem in facing in both directions. The obvious difficulty was that, on commercial competitive grounds,<sup>256</sup> the SNBTS needed to introduce screening, but on scientific and value for money for the health service grounds they should be opposing it. He did not know if there was any way out of this dilemma.<sup>257</sup>

**27.172** In due course Dr Gunson was sent a copy of the minutes of the meeting of the SNBTS Directors of 3 March 1987. By letter dated 21 April he advised Professor Cash that he was 'dismayed' that the SNBTS Directors were putting forward proposals for the funding of surrogate tests for NANB Hepatitis in Scotland from 1 April 1988.<sup>258</sup> Dr Gunson enclosed a copy of the proposals for research submitted by the UK Working Party on Transfusion Associated Hepatitis. Edinburgh was included as a participating RTC (contrary to what was stated in the minutes of the meeting of 3 March that there were no participating Scottish RTCs). The cost of participation by the Edinburgh Centre was not to be met from non-recurring funds; a bid would probably be made to the Chief Scientist for a research grant. He stated:

This decision seems to go against the proposal ... to which I thought that the SNBTS was a party.<sup>259</sup> Of course, I accept that it might be prudent to have funds ear-marked should the recommendation of the study be that such testing should be introduced, but the tenor of this minute does not suggest that consideration of the results of the multi-centre [study] would be a factor before introducing surrogate testing. Also, I recall your telling me that Scotland would not take unilateral action in this matter without consultation with RTDs in England and Wales.<sup>260</sup>

<sup>254</sup> Ibid page 144

<sup>255</sup> Day 63, page 127

<sup>256</sup> Presumably a reference to the competitive advantage of American screened products as against blood products from the PFC and Scottish blood. That, and the BPL's interest in exporting excess blood products, emerged explicitly about a year later as factors supporting ALT testing. See paragraph 27.231

<sup>257</sup> Memorandum from Dr McClelland to Professor Cash, dated 15 April 1987 [SNB.006.0715]

<sup>258</sup> Letter [SGH.001.6628]

<sup>259</sup> The proposal to undertake a multi-centre study into surrogate markers in donors, as agreed at the meeting of the re-convened Working Party on Transfusion-Associated Hepatitis on 24 November 1986.

<sup>260</sup> Letter from Dr Gunson to Professor Cash, dated 21 April 1987 [SGH.001.6628] at 6628–6629

**27.173** Professor Cash replied on 27 April. He stated:

I don't think you should take the content of minute 3(f), with regard to the introduction of surrogate testing for NANB, too seriously at this stage. I think it would be appropriate to say that it was a decision made with our PESC submission in mind and, I suspect, a view that we have often expressed – that the results of the UK study are unlikely to have a material affect on future operational practice.<sup>261</sup>

**27.174** In oral evidence Professor Cash explained that in that letter:

I think I was conveying something that Harold [Gunson] actually knew from our conversations, that whatever submission we made, and however we thought we may go off on our own, we couldn't and wouldn't, simply because we would need significant funding and this would have to be approved by the [SHHD].

So any panic that he had in seeing these things, he could relax because this would all be part of the UK exercise, hence reference to the PESC submission.

I think I was also explaining to him, which he knew very well, that we didn't really think the currently floated new study of the transfusion hepatitis working party would materially affect any of the ultimate outcomes in terms of practice, if we in fact implemented it all.<sup>262</sup>

**27.175** Professor Cash was asked at the Inquiry how serious the Directors' recommendation to introduce surrogate testing was and he replied:

[I]t was serious in the sense we were trying to alert the people, the minister, ultimately, that things were happening outside the UK that we believed – we were not certain – could have an influence upon us; and that concept was very serious indeed.<sup>263</sup>

**27.176** He continued:

What I'm meaning for him [Dr Gunson]: do not take it seriously in [the] sense you are going to wake up tomorrow morning and the Scots are testing and you are caught. That is what I was signalling to Harold.<sup>264</sup>

**27.177** Professor Cash was asked whether the position of the SNBTS was that it was alerting the SHHD to something which might be on the horizon and which might be unstoppable and that there might be a need to make provision for funding it. He replied: 'Absolutely. We were later to discover that Brian McClelland's opinion was doing a big study – we were too late. The whole world was moving on and we accepted that, perhaps too easily, but we accepted that.'<sup>265</sup> Professor Cash stated that the position of the Directors, ultimately, was that they did not wish to introduce surrogate testing because they did not have clear evidence of its value (because a large scale prospective study had not been carried out in the UK) but they thought they might have to introduce such testing because

<sup>261</sup> Letter from Professor Cash to Dr Gunson, dated 27 April 1987 [SGH.001.6627]

<sup>262</sup> Day 70, page 185

<sup>263</sup> Ibid page 188

<sup>264</sup> Ibid page 189

<sup>265</sup> Ibid

other countries either had done so or were moving in that direction. He said, 'we felt we were drifting, and the effort we made was one last effort to stop the drift and get people to sit down and seriously talk about it'.<sup>266</sup> He went on: 'I think what we want and what we are being forced into by dint of other people's practice doesn't, sometimes, match.'<sup>267</sup>

**27.178** On 14 May 1987 Dr Forrester sent a memorandum to Dr McIntyre, Dr Scott and Mr Macniven.<sup>268</sup> He reported that the outcome of Dr Gillon's discussions with Dr Forbes was that the Scottish component of the UK NANB Hepatitis research project was being abandoned. He said that Dr Gillon's Director, Dr McClelland, was unlikely to press it as his current view was that the SHHD had better simply institute screening.

**27.179** On 19 June 1987 Dr Archibald McIntyre, SHHD, wrote to Professor Cash about Scottish participation in the proposed UK research project on transfusion-associated NANB Hepatitis.<sup>269</sup> Dr McIntyre noted that there appeared to have been some confusion on the subject. He observed that on 22 April application forms for funding had been sent to the Edinburgh and South East Scotland RTC. For reasons Dr McIntyre had not fully understood, it was decided by the RTC not to proceed with the application. Following a telephone conversation on 15 June between Dr McIntyre and Professor Cash, Dr McIntyre understood that the SNBTS did now wish to proceed with the research project and would submit an application to the CSO for funding. The application would be considered at the meeting of the Biomedical Research Committee on 25 September. The outcome of the research would have considerable implications as it was unlikely that funds would be made available for the routine screening of blood donations for NANB Hepatitis unless it could be clearly shown that such screening was practicable and worthwhile.

**27.180** In due course, the SNBTS PES bid submitted in 1987 made provision for the introduction of surrogate testing, for expenditure in 1988–89 and 1989–90, on the basis that it was likely that a new mass screening programme would commence in the foreseeable future.<sup>270</sup> It was suggested that surrogate screening might be made a special project with separate funding. The accompanying narrative stated:

The SNBTS Directors have now decided that in the light of the advent of new Product Liability laws in 1988 and an emerging unchecked private sector blood collection services<sup>271</sup> it would be prudent to plan to commence this programme in the financial year 1988/89. The costing are estimates only and it is proposed that we plan to ensure the financial burden covers two financial years but begin in July 1988 (the date new Product Liability legislation will be introduced).<sup>272</sup>

**27.181** The initial provisions were for £300,000 for 1988–89 and £105,000 for the following year. At that stage there was no provision for 1990–91.

**27.182** At their meeting on 10 June 1987 the SNBTS Directors noted Dr Gunson's letter of 27 April to Professor Cash and Professor Cash's reply.<sup>273</sup> It was noted that Dr McClelland

would probably apply to the next meeting of the Chief Scientist's Office<sup>274</sup> for a research grant in respect of the cost of participation by the Edinburgh centre in the proposed UK research into surrogate testing. The need for synchrony with England and Wales was noted.

### The Scottish Home and Health Department

**27.183** The evolving position of the Transfusion Directors from the early summer of 1986 to the spring of 1987 reflects a degree of inconsistency of approach among them on the question as to whether surrogate testing should be introduced. On the other hand, the SHHD had consistently resisted the introduction of surrogate testing: as already noted, Dr Forrester indicated at the SNBTS Directors' meeting on 25 March 1986 that it was unlikely that the UK Departments of Health would fund testing on the basis of data from the USA (paragraph 27.120 above); Dr Forrester's advice to colleagues on 12 June 1986 summarised his reasons against introduction of surrogate testing at that time (paragraph 27.129 above); and the SNBTS bid for funding in the PES programme for 1987-88 was rejected prior to 2 October 1986 (paragraph 27.141 above).

**27.184** While Dr Forrester was present at the meeting of the SNBTS Directors on 3 March 1987 at which the recommendation to introduce surrogate testing was made, the Inquiry has been unable to recover a copy of any note he sent his medical or administrative colleagues reporting on the meeting or the recommendation that surrogate testing should be introduced. In his evidence to the Inquiry, Dr Forrester had no recollection of the meeting or recommendation but did not think that he would have been the messenger for transmitting the recommendation to the SHHD and thought, instead, that it would have been transmitted formally, in writing, through a different channel, perhaps via the PES funding bid.<sup>275</sup>

**27.185** Regardless of the means by which the Directors' recommendation was supposed to reach the SHHD, it is clear that the SHHD was aware of the Directors' recommendation that surrogate testing should be introduced, as Dr McIntyre's minutes to Drs Scott, Forrester and Moir and Messrs Morison and Macniven dated 6 April 1987 show.

**27.186** Dr McIntyre's minute to Dr Moir dated 6 April 1987, explained that the bid by the SNBTS of £810,000 to introduce surrogate screening of all donations in 1987-88 was not advanced because:

[T]he research already conducted in the West of Scotland with CSO<sup>276</sup> funding indicated that the impact there of transfusion-associated '[NANB] Hepatitis' was not great; also that the indirect screening proposed would be expensive, could not in any event abolish the transmission of this 'Hepatitis' by blood and blood products, and would lead to a loss of a perceptible amount of 'innocent' blood which nevertheless failed to pass the screen. We also wished to await DHSS thinking on this subject.<sup>277</sup>

**27.187** He reported that the DHSS had now invited the UK Transfusion Associated Hepatitis Working Party to consider the issue.

---

<sup>274</sup> The minute refers to 'the Chief Scientist's Organisation' but it is assumed this is a typographical error.

<sup>275</sup> Day 66, pages 32-34 and 55

<sup>276</sup> Chief Scientist Office

<sup>277</sup> Minute [SGH.002.8127]

**27.188** On the question of Scottish participation in the proposed UK multi-centre study into surrogate markers in donors, the minute stated:

The Directors of SNBTS are unanimous, and are now pressing fairly strongly, that this screening should be instituted; though perfectly aware that it would be costly and could not abolish transmission [of NANB Hepatitis] completely, they could then claim to have taken all steps open to them to reduce transmission. Before embarking on such an expensive programme it would seem logical to participate in the proposed research<sup>278</sup> and to delay any further action until the results of this were known.

If recipients of this minute are agreeable that this is the correct line to adopt then the Edinburgh SNBTS will be asked to prepare a detailed proposal along similar lines to that of their English counterparts.<sup>279</sup>

**27.189** The minute contained a handwritten note by Mr Hugh Morison<sup>280</sup> as follows:

Mr Macniven,

Advise please. My initial reaction is -

- (a) it would not make sense to screen all blood for [NANB Hepatitis] as benefits appear out of all proportion to the risks,
- (b) we should therefore participate in the research,
- (c) CSO should be encouraged to fund it.<sup>281</sup>

**27.190** In a minute dated 7 April 1987 Dr Scott, DCMO, agreed with Dr McIntyre that further research should be carried out into surrogate testing, stating:

We must do whatever we can to prevent the BTS going ahead with a full scale introduction of this testing – or at least trying to blackmail us into the provision of funds.

The research proposal from Edinburgh will of course have to be subject to the scrutiny of the appropriate CSO group and the availability of finance. I would not like to see it fail on the grounds of finance because the stakes are high.<sup>282</sup>

**27.191** Mr Macniven responded on behalf of himself and Mr Morison. They agreed with the comments in Dr Scott's minute and expressed the view that:

It is important that the decision on whether or not to screen all blood for [NANB] Hepatitis, which will not be cheap and may not be certain, should be taken on the basis of the sort of UK research you suggest.<sup>283</sup>

**27.192** The strong support of the SHHD for the multi-centre study proposed by the Working Party on Transfusion Associated Hepatitis seems, on the face of it, surprising given Dr Forrester's note following the meeting of the Working Party on 24 November 1986 that the proposed research was 'of no great significance or scientific interest'.<sup>284</sup>

---

<sup>278</sup> The multi-centre study into surrogate markers in donors proposed by the Working Party on Transfusion Associated Hepatitis

<sup>279</sup> Minute [SGH.002.8127] at 8128

<sup>280</sup> Mr Macniven identified the handwritten note as having been written by Mr Morison: Day 65, page 175

<sup>281</sup> Minute [SGH.002.8127]

<sup>282</sup> Minute [SGH.002.8127] at 8128

<sup>283</sup> Minute by Mr Macniven dated 9 April 1987 [SGH.002.8125]

<sup>284</sup> Dr Forrester's note [PEN.017.1554] at 1555

Similarly, it is not entirely clear what Dr Scott meant in his minute of 7 April 1987, above, that he would not like the research proposal to fail on the grounds of finance 'because the stakes are high'.

**27.193** In his evidence to the Inquiry Dr Macdonald stated:

I think one must be truthful and say that – and I think this applied at that stage [late 1986] to – certainly to the directors in England and perhaps a bit later for the ones in Scotland. But we were really trying to, I think, give ourselves a bit more time and not be rushed by the pressure coming from the commercial producers.<sup>285</sup>

**27.194** Dr Macdonald was later examined as follows:

Q: [One] might think ... that there was a preoccupation within SHHD with undertaking research, whatever its purpose, at all costs, as a means of putting off making a decision about surrogate testing ....

A: I think it was reasonable to argue that we didn't have sufficient information to know exactly how it would work out in our population and therefore we should look to the possibility of research. At the same time, I think it has to be admitted that that would postpone a final decision inevitably.

Q: But was it the postponement of the final decision that was really the priority at this time?

A: It certainly – it is certainly fairly clear that neither DHSS nor SHHD were persuaded that we should go ahead with surrogate testing.<sup>286</sup>

**27.195** The reasonableness of the SHHD position is discussed further below.

### Correspondence in *The Lancet*

**27.196** The picture in the second half of 1987 is confused, with different groups of Scottish experts expressing apparently conflicting views. Debate on the introduction of surrogate testing became focused in a chain of correspondence in *The Lancet* beginning in June, to which SNBTS specialists contributed. It is necessary to note the positions that had been reached in research by Scottish scientists by June. The work of Dr Dow and Dr Follett has been discussed above. As noted in paragraph 27.127 above, Dr Dow's view was that there was a low level of post-transfusion NANB Hepatitis in the West of Scotland region (with 23 possible cases reported in eight years) and that the introduction of screening would have little impact. In Edinburgh and the East of Scotland, Dr Gillon and colleagues had carried out research between April and November 1986 into ALT activity in a cohort of regular blood donors.<sup>287</sup> They had concluded that the introduction of ALT/anti-HBc screening tests as an indicator of NANB Hepatitis carrier status in blood donors could not be justified at that stage.

---

<sup>285</sup> Day 66, page 141

<sup>286</sup> Ibid pages 162–163. See also, the views expressed in the DHSS minute of 29 January 1988 discussed below [PEN.016.0216]

<sup>287</sup> The results of which were first reported on 13 June 1987 in the course of the debate in *The Lancet*: Gillon et al, 'Non A, Non B Hepatitis Surrogate Testing of Blood Donations', *The Lancet*, 1987; 1366-67 [LIT.001.0346]. They were more fully reported in 1988: Gillon et al, 'Post-transfusion [NANBH]: significance of raised ALT and anti-HBc in blood donors', *Vox Sanguinis*, 1985; 54:148–153 [SNB.008.3536].

**27.197** The chain of correspondence in *The Lancet* began with a letter from Dr Catherine Anderson and colleagues at the North London BTC, Edgware, in April 1987, arguing against the introduction of surrogate testing without further research.<sup>288</sup> The authors argued that a national study was required to assess the incidence of raised ALT levels and anti-HBc in donors in different parts of the country; the incidence of acute post-transfusion NANB Hepatitis; and how many of those affected developed evidence of chronicity and serious clinical sequelae. The authors concluded:

Before we are forced to accept two screening tests of unproven benefit, which have high revenue implications, we need a national study to assess the incidence of raised ALT and anti-HBc in donors in different parts of the country. Also, and perhaps more importantly, a study is needed to assess the incidence of acute post-transfusion NANB hepatitis and to assess how many of those affected develop evidence of chronicity and serious clinical sequelae.

If the true incidence of post-transfusion NANB hepatitis and its serious clinical sequelae are at a much lower level than reported from the USA, then screening of donations to reduce the incidence of NANB hepatitis may not be cost effective in the UK.<sup>289</sup>

**27.198** In effect, the Edgware RTC group was repeating the call for a large, prospective, well organised and resourced study of post-transfusion NANB Hepatitis originally put forward by Dr McClelland in 1980–81.

**27.199** A similar view was expressed on 2 June 1987 in a paper by Dr Valerie Mijovic and colleagues (also at the North London BTC) reporting on a study of ALT testing in 2000 North London blood donors.<sup>290</sup> The percentage of the total donor population with raised ALT levels (4.6%) was greater than that found in earlier studies at the same centre in 1973 (2.8%) and 1982 (3.1%). The increase in donors with raised ALT values had occurred despite the intensification of donor education and the subsequent self-exclusion of donors in groups at high risk of HIV. The authors considered that as confirmation that many other factors, apart from NANB Hepatitis, affected ALT activity. Those other factors included high alcohol consumption, obesity, medication, strenuous activity and inhalation of solvents. The authors stated:

Before we even consider testing blood donors for ALT, a well designed prospective trial is needed to compare the incidence of hepatitis associated with transfusion in patients who have received blood only from donors with normal ALT activities with those receiving untested blood .... [E]ven in the United States the predictive value of ALT testing of blood donations for NANB hepatitis is very poor. The costs of testing and discarding donor blood would need to be examined as well as the costs of informing and counselling donors found to have ALT values repeatedly above the normal, or donors with excessively high values at any one time. Extrapolating data from the United States to this country without knowing the magnitude of the problem or its preventability would be ill advised.<sup>291</sup>

---

<sup>288</sup> Anderson et al, 'Surrogate testing for [NANB] hepatitis', *The Lancet*, 1987:912 [LIT.001.1854]

<sup>289</sup> Ibid [LIT.001.1854]

<sup>290</sup> Mijovic et al, 'Serum [ALT] and  $\gamma$ -glutamyltransferase activities in north London blood donors', *Journal of Clinical Pathology*, 1987; 40:1340-1344 [LIT.001.3907]

<sup>291</sup> Ibid [LIT.001.3907] at 3911

**27.200** In his evidence to the Inquiry Dr McClelland stated that he could not remember his reaction at the time to the suggestion by Anderson and colleagues that a prospective study should be carried out before surrogate testing was introduced but said:

I think I was in one sense probably glad that somebody was saying what I had been trying to say for quite a long time but at the same time ... I was aware that the study would take several years and I think I would probably have felt it was a bit late....

I felt that we had been prevaricating about this for a long time, and to sort of prevaricate for another three years, which was the minimum time it would have taken to do a decent prospective study, we were too late.<sup>292</sup>

**27.201** The suggestion had a greater impact on Dr Dow and Dr Gillon, and their respective research colleagues.

**27.202** In a letter in *The Lancet* on 13 June 1987 Drs Dow, Mitchell and Follett of Glasgow reported on Dr Dow's study of post-transfusion hepatitis in the west of Scotland. Their findings were analysed briefly and said to indicate that if ALT and anti-HBc tests had been carried out routinely over the eight-year period of their study, at an estimated cost of more than £1 million, with a loss of about 4% of the blood supply, only five of the reported cases of infection might have been prevented. They expressed the view that:

It would be prudent to do a UK study to assess the real incidence of acute post-transfusion NANB hepatitis and to assess the proportion of those chronically affected, before considering following the American surrogate testing policy.<sup>293</sup>

**27.203** In the same edition of *The Lancet*, Dr Gillon and his colleagues at Edinburgh reported the findings of their 1986 study into surrogate markers in blood donors attending their centre.<sup>294</sup> It stated:

Our findings confirm the doubts expressed by Dr Contreras and her colleagues [at Edgware] on the wisdom of introducing surrogate testing for NANB hepatitis into blood transfusion practice in the UK. We found a strong association between a raised ALT and both obesity and alcohol ingestion, and these two factors alone might account for 82% of the abnormal ALT values found .... Those who support ALT testing should recognise the tendency ... of ALT levels to fluctuate: the loss of donated blood would be far in excess of that suggested by published studies, and most of the excluded donors would not be NANB hepatitis carriers.

If the degree of benefit claimed from the retrospective American studies were to hold for the UK, the blood transfusion services would have to spend well over £5 million more every year (2½ million donations at £2-3 per donation). Account must also be taken of the consequences of identifying up to 5% of the donor population as being potential carriers – not just the costs of further laboratory tests, clinical assessments, and counselling but also the anxiety raised in the donors themselves.

---

<sup>292</sup> Day 63, pages 130–1

<sup>293</sup> Dow et al, 'NANB hepatitis surrogate testing of blood donations', *The Lancet*, 13 June 1987 [LIT.001.0346]

<sup>294</sup> Gillon et al, 'Non A, Non B Hepatitis Surrogate Testing of Blood Donations', *The Lancet*, 13 June 1987; 1366-67 [LIT.001.0346]

The Americans have concluded that a large, prospective, randomised trial to test the hypothesis that surrogate testing carries clinical benefit will never be done. Of the four small prospective studies, two using ALT screening and two using anti-HBc, three failed to demonstrate any reduction in post-transfusion NANB hepatitis as a result of donor screening and one found an apparent association between anti-HBc in donor units and recipient hepatitis.<sup>295</sup>

We conclude that the introduction of ALT/anti-HBc screening tests as an indicator of NANB hepatitis carrier status in blood donors cannot at present be justified.<sup>296</sup>

**27.204** In his evidence to the Inquiry, Dr Gillon said:

I think nobody would have denied that introducing surrogate testing would have identified some donors who were carriers of [NANB] Hepatitis. We knew that. We just didn't know how many. We didn't know enough about whether this test would perform as it was being predicted in the American literature.<sup>297</sup>

**27.205** Dr Gillon also advised that he had visited the USA in early 1985 and was aware of work being done there, and elsewhere, to try to identify the agent or agents responsible for NANB Hepatitis. While he had no particular knowledge in 1987 that a breakthrough was imminent, he said:

[T]he other thing I had in my mind was that there was the likelihood that there would be a scientific solution to this problem, we would hope in a very short time ....

....

[T]o say that ALT was the only show in town was perhaps true, but it's not that we didn't have other avenues that were opening up in a much more rigorously scientific way of dealing with this problem.<sup>298</sup>

**27.206** On 16 June 1987, three days after these letters had been published in *The Lancet*, the SNBTS Co-ordinating Group held an extra meeting.<sup>299</sup> All of the Scottish Transfusion Directors were present, along with Professor Cash and Mr John Francis of the SNBTS Finance Department. The SNBTS scientists contributing to *The Lancet* correspondence were not represented. Their view that surrogate testing was not justified on scientific grounds was noted, however, and acknowledged by the Directors. Dr McClelland tabled a draft letter to *The Lancet* 'in expansion of the SNBTS view of the need to commence surrogate marker screening of blood donations for NANB in the context of product liability and of competition from commercial producers who would be introducing it'.<sup>300</sup> After a few editing points were made the Directors agreed the terms of the letter.

---

<sup>295</sup> These studies are discussed later in this chapter

<sup>296</sup> Gillon et al, '[NANB] hepatitis surrogate testing of blood donations', *The Lancet*, 13 June 1987 [LIT.001.0346] at 0346-7. Dr Gillon's full paper was published in *Vox Sanguinis* in 1988 [SNB.008.3536]

<sup>297</sup> Day 65, page 76

<sup>298</sup> Ibid pages 87-88

<sup>299</sup> Minute of Meeting [SNB.004.0672]

<sup>300</sup> Ibid [SNB.004.0672] at 0674

**27.207** The letter from the SNBTS Directors was published in *The Lancet* on 4 July 1987 under the title, 'Testing blood donors for [NANB] hepatitis: irrational, perhaps, but inescapable'.<sup>301</sup> In the letter the Directors noted the recent correspondence by Drs Anderson, Dow and Gillon and colleagues to the effect that the UK transfusion services should not start donor screening until prospective controlled studies had been carried out in the UK to find out how many cases of post-transfusion hepatitis would be prevented. While the SNBTS Directors agreed that the size of the benefit to be gained from surrogate testing could not be accurately established without such a study, they considered that the time for such a study had already passed: 'Starting now will give us an answer in 3-4 years – and that is probably 3 to 4 years too late'. That conclusion clearly reflected Dr McClelland's considered position at this stage and his oral evidence was consistent with it.

**27.208** The letter stated that the introduction of surrogate testing was 'virtually inescapable' for a number of reasons. In summary, these were:

- Legislation would soon come into force providing for strict liability for harm caused by products unless all known methods had been taken to avoid the risk.
- Surrogate testing might modestly reduce the level of infectivity of pooled plasma products, in particular, pending the validation of methods of viral inactivation in large-scale trials and many would argue that some improvement was better than none.
- The UK transfusion services could not ignore the wishes of consumers to be supplied with 'NANB tested' products, when such testing had been introduced by commercial manufacturers who would market their products as being safer.
- Having regard to the number of cases of post-transfusion hepatitis that may be prevented, the cost of preventing morbidity by surrogate marker testing for NANBH might be no greater, and could be less, than that accepted for existing screening tests for Hepatitis B and HIV.

**27.209** In their letter the Directors concluded that 'the decision which has to be made is when rather than whether the UK transfusion services follow the lead of the United States and other European countries in donor screening'.<sup>302</sup>

**27.210** Dr McClelland was asked how strongly the various SNBTS Directors felt at the time about the issue of surrogate testing and replied that most of them were still 'pretty lukewarm' and that he didn't think they were 'enthusiastic'.<sup>303</sup> He explained that part of the reason he had drafted the letter was that:

[H]aving repeatedly failed to get anywhere ... on grounds of patient safety ... I thought it might be worth deploying some other arguments, because people were worried about ... the European directive on strict product liability which was about to be translated into the Consumer Protection Act, and that was quite exercising people in the transfusion service at this sort of time.<sup>304</sup>

<sup>301</sup> McClelland et al, 'Testing Blood Donors for Non-A, Non-B Hepatitis-Irrational perhaps but inescapable,' *The Lancet*, 1987:36 [LIT.001.0328]. The reference to surrogate testing being 'irrational' was a reference to a lack of scientific data, in particular, in the UK, that proved the efficacy of such testing in reducing the incidence of post-transfusion hepatitis: Professor Cash – Day 70, pages 194–195

<sup>302</sup> McClelland et al, 'Testing Blood Donors for Non-A, Non-B Hepatitis – Irrational perhaps but inescapable', *The Lancet* 1987, ii:36 [LIT.001.0328] at 0329

<sup>303</sup> Day 63, page 137

<sup>304</sup> Ibid pages 137–138

**27.211** Professor Cash was asked whether, although the ultimate decision was unanimous, some Directors had been uneasy about the idea of surrogate testing. He replied:

I think that all of us, certainly including myself, but all of us were very uncomfortable with finding our position – and we were not in that letter recommending the introduction; we were saying, “It’s too late. We are going to be forced into doing it.” But none of us wanted to go down that track and I think it is quite important that I make that very plain ....<sup>305</sup>

**27.212** He continued:

[A]ll of you keep saying we recommended it. We just simply said, “It’s inevitable. It’s going to happen. We are going to be caught here and we need to plan for that eventuality.”

....

[W]e were all very unhappy about this. We were not saying, “This is excellent, let’s go for it”. We were saying, “We are caught”... [P]lease, we did not recommend that we started it. We simply said, “The writing is on the wall, we think, as best we can judge”.<sup>306</sup>

**27.213** In his evidence to the Inquiry, Dr McClelland confirmed that he was of the view at that stage that surrogate testing, using both ALT and anti-HBc, should be introduced. He was asked for the main or the determining factor or factors that led him to recommend that surrogate testing should be introduced and replied:

I felt there was – even in the absence of a proper ... a definitive prospect of [a] randomised controlled study to provide a real answer, that there was sufficient evidence – the evidence which had convinced the Blood Products Advisory Committee of the FDA that surrogate testing needed to be introduced and led to the decision in the United States was, while not complete and not definitive, very, very difficult to ignore and I had no conviction that the epidemiological situation, the sort of prevalence, the amount of ... [NANB] Hepatitis infection in the UK was really that much less than it was in America, in 1986, because, you know, commercial paid donors had stopped. They had introduced similar changes in donor selection in relation to AIDS that we had, and I felt if, in the light of ... those two major changes, the United States felt it had to introduce this testing, we were in a very, very poor position to not follow suit in the UK, unless we had convincing evidence that it really genuinely wasn’t a problem .... And we didn’t have that.<sup>307</sup>

**27.214** As indicated in paragraph 27.208, Dr McClelland was deploying different arguments. It was, as he said, his ‘sort of last throw on this topic’. When asked to what extent patient safety was a factor in his consideration he replied it was ‘the’ factor in his consideration.<sup>308</sup> He went on to explain that his view was essentially an application of the precautionary principle: he was concerned that ‘despite the persisting uncertainties about the real safety gains that might be achieved, failure to introduce testing could constitute

---

<sup>305</sup> Day 72, pages 78–79

<sup>306</sup> Ibid pages 81–82

<sup>307</sup> Day 63, pages 141–142

<sup>308</sup> Ibid pages 143–144

a failure to protect patients from some degree of avoidable risk'.<sup>309</sup> There was evidence which, while imperfect, suggested that surrogate testing might increase the safety of blood, and:

[I]f something might make a patient safer, then you have to do it. That is in a very crude way, as I understand [it] ... the precautionary principle. And depending on whether you are a health economist or concerned primarily with the nation's economics or whether you're concerned with the public health or you are concerned with the health of an individual, you will view those things in different ways. There ain't no right answer.<sup>310</sup>

**27.215** Whether or not justified on the precautionary principle, the letter exposed the conflicting opinions within the SNBTS at this stage, in mid-1987. The letter also attracted considerable criticism and a degree of confusion about its purpose and the intentions of the SNBTS. The SNBTS Directors later acknowledged, at their meeting on 18 August 1987, that the rapid succession of the publications by the scientists and by the Directors 'had caused readers of *The Lancet* to be puzzled'.<sup>311</sup> Dr Mitchell, for example, had been a co-author of the letter published in *The Lancet* on 13 June 1987 which argued against the introduction of surrogate testing until further studies had been carried out, but was also a signatory to the letter of 4 July 1987 in which the SNBTS Directors argued that the time for further studies had passed and that the introduction of surrogate testing was virtually inescapable.

**27.216** Professor Cash had sent a pre-publication copy of the Directors' *Lancet* letter to Dr Fraser (Bristol) who replied on 2 July 1987, advising that:

I think you will find that the Transfusion Directors in England and Wales will not be very pleased at reading this letter.

....

We all managed to work together to introduce HIV antibody testing on the same date. I think it is only a shame that we have not been able to have the same type of discussion to agree whether or not to implement ALT and/or core antibody testing in the UK.<sup>312</sup>

**27.217** Professor Cash replied to Dr Fraser on 8 July 1987. He stated:

1. The SNBTS Directors do not wish, and currently have no intention, of introducing NANB surrogate testing unilaterally.
2. Current views, which as you know were crystallised last March, are being expressed to support our Public Expenditure Survey (PES) submissions to SHHD for the next 5 years.
3. We have no doubt that an important forum for the continued debate is indeed the BTS/NIBSC group(s) and the current NANB debate (which began some 2 years ago here) and the confused central management attitudes to the

<sup>310</sup> Day 63, pages 147–8. Dr McClelland accepted that there was a limit on the proposition that blood should have 'maximum safety' in that a proposal which offered minimal additional safety at enormous cost may not be worthwhile: Day 63, page 153

<sup>311</sup> Minute of Meeting [SNB.004.0728] at 0733

<sup>312</sup> Letter [SNB.008.3507]. On 1 August 1987 *The Lancet* published a letter by Drs Contreras and Barbara of the North London BTC, Edgware, taking issue with the views of the SNBTS Directors: see paragraph 27.218 below

Medicines Act and Product Liability had much to do with driving me to seek the establishment of this joint enterprise.

4. I really don't believe you should view The Lancet letter as any more than part of a debate which was initiated in this journal's columns by our friends and colleagues at Edgware. It can also be viewed as yet another attempt to persuade central management (DHSS) to give renewed thought to the way the transfusion services interface with the Medicines Act and forthcoming legislation on product liability and perhaps even to ways for improving the co-ordinated management of the transfusion services on a UK basis.<sup>313</sup>

**27.218** In a minute dated 21 July 1987, Dr McIntyre brought the SNBTS Directors' *Lancet* letter to the attention of Mr Macniven and others. In the minute Dr McIntyre stated:

The purpose of this minute is not to discuss all the relevant issues, but to point out that SNBTS may institute testing without further discussion as a fait accompli.

....

Professor Cash has assured Dr Fraser of Bristol NBTS, in a letter dated 8 July, that he will not institute testing 'unilaterally'. We have however no assurance that he will not do so in the near future without specific funding and without necessarily reporting what he has done to CSA or SHHD.

DHSS have expressed their concern and dismay at the letter by Professor Cash and colleagues and have interpreted this as being SHHD policy; we have attempted to reassure them that it is not so. Their concern is that if we should commence testing unilaterally they will feel obliged to follow.<sup>314</sup>

**27.219** It was noted that the SNBTS had been given the opportunity to engage in a research programme to evaluate the need for testing but had declined as they felt that the time for this study had already passed.<sup>315</sup> The background to that comment was confused. As indicated in paragraph 27.159 above, the proposal for Scottish participation in the UK programme envisaged in early 1987 was directed into the CSO funding process by Dr Moir, SHHD. The project seems to have made little progress for some time after that point, but was revived ('after much manoeuvring' by the SHHD)<sup>316</sup> in June 1987 when it was decided that an application would be made to the CSO. It was made in the names of Dr McClelland and Dr Gillon on 6 August but was later rejected.<sup>317</sup>

**27.220** The debate in *The Lancet* continued. Two English Directors, Drs Contreras and Barbara, responded to the Scottish Directors' letter to *The Lancet* in the edition published on 1 August. They argued that the transfusion service must not bow to irrational pressure to introduce surrogate screening, described as 'measures whose efficacy is unproven'.<sup>318</sup>

<sup>313</sup> Letter [SNB.011.3846]

<sup>314</sup> Minute [SGF.001.2085]

<sup>315</sup> In the event, an application for funding for the research project was made by Drs Gillon and McClelland and was refused on 25 September 1987.

<sup>316</sup> Memorandum by Dr Forrester to Mr Macniven dated 1 October 1987 [SGH.002.8077]

<sup>317</sup> Paragraph 27.229 below

<sup>318</sup> Contreras and Barbara, 'Testing of Blood Donations for Non-A, Non-B Hepatitis', *The Lancet*, 1 August 1987 [LIT.001.0326]

**27.221** At their meeting on 18 August 1987 the SNBTS Directors noted reactions to the Scottish Directors' letter to *The Lancet*.<sup>319</sup> Dr McClelland's application to the Chief Scientist Office for funding to enable him to participate in the UK study was reported. The Directors agreed that to be consistent with their policy decision (on the introduction of screening) it would be prudent to proceed to a Scottish national study to evaluate ALT and anti-HBc testing. Dr Cuthbertson and the SNBTS Microbiological Validation Group would consider how the SNBTS should examine the available technology for these tests.<sup>320</sup> At this stage, therefore, there were two lines of research for which funding would be required: Dr McClelland's UK project and a national Scottish project that had been remitted to the SNBTS Microbiological Validation Group.

**27.222** Preparatory work was started to cover the possibility that surrogate screening might be introduced. On 6 October 1987 the SNBTS Directors were told that Dr Cuthbertson's SNBTS/NBTS Microbiological Validation Group was due to make a proposal to the Directors concerning ALT and anti-HBc testing methodology.<sup>321</sup> The SNBTS Directors met on 8 December 1987.<sup>322</sup> It was reported that the Microbiological Validation Group was to reconsider to what extent it was necessary for every centre to be involved in evaluating the technology for ALT testing and would report on the matter by 31 March 1988. It was agreed not to consider anti-HBc testing until the report on ALT testing had been received and discussed by the Scottish Directors.<sup>323</sup> That work did not proceed quickly, however; when the SNBTS Directors met on 13 December 1988, it was reported that the Validation Group had not done any significant work since the last meeting. The Directors agreed that the group 'had more important matters to fulfil'.<sup>324</sup> The proposal for a national Scottish evaluation of surrogate screening appears to have proceeded no further after that point.

**27.223** Meanwhile, the commercial pressure anticipated by the Scottish Transfusion Directors in 1987 was indeed to become a reality and was noted within the SHHD. On 17 December 1987 Dr Forrester sent an internal SHHD memorandum to Mr Tom Macdonald and others.<sup>325</sup> He noted that commercial producers of blood products were being allowed by the DHSS to include in their product inserts a statement that the product was derived from donations which had been ALT tested and that that was likely to stimulate pressure for the introduction of surrogate testing in Scotland.

### Funding for Edinburgh RTC to join the multi-centre study

**27.224** As noted in paragraph 27.219, Drs Gillon and McClelland submitted an application to the Chief Scientist Office (CSO), SHHD, on 6 August 1987 for a research grant to enable the Edinburgh RTC to participate in the proposed UK multi-centre study into surrogate markers in donors.<sup>326</sup>

<sup>319</sup> Minutes of SNBTS Co-ordinating Group meeting, 18 August 1987. [SNB.004.0728] at 0732–0733

<sup>320</sup> The Microbiological Validation Group subsequently investigated the technology for carrying out ALT testing. A final report of the evaluation of the Eppendorff Epos system was produced on 25 August 1988 and concluded that the system was clearly suitable and that a cut-off of 2.5 Standard Deviations above the mean would lead to the exclusion of approximately 1.5% of donations whereas a cut-off of 2 Standard Deviations above the mean would lead to the exclusion of approximately 5% of donations [SNB.002.4423]. Similar work to evaluate anti-HBc testing technology appears to have been started but not concluded. See extract from minutes of SNBTS Directors' Meeting, 27 September 1988 [SGH.002.8027] and minutes of the SNBTS Directors' meeting, 13 December 1988 [SNB.002.7350] at 7353.

<sup>324</sup> Minutes of SNBTS Directors Meeting, 13 December 1988 [SNB.002.7350] at 7353

<sup>325</sup> Minute from Dr Forrester to Mr Macdonald, dated 17 December 1987 [SGH.002.8062]

<sup>326</sup> Grant application by Drs Gillon and McClelland dated 6 August 1987 [SNB.006.0791]

**27.225** On 20 August 1987 Dr Forrester (SHHD) sent a memorandum to Dr William Forbes (CSO) and others.<sup>327</sup> Dr Forrester wrote that the Department was required to make a well-informed decision on whether or not to support surrogate testing of blood donations for NANB Hepatitis. The benefits of such testing were not clearly established and there were drawbacks. The memorandum suggested a lack of significant support for the project at this stage. It stated:

The Department are well aware of the work by Dr Dow supported by CSO, and indeed so are the organisers of the current application .... The Department however do not believe that his work alone is a sufficient guide at present, because:

- It did not study [anti-HBc] ....
- More searching investigation is now possible into the significance of these antibodies ....
- It took place before the advent of screening for HIV antibodies, which may exclude some donations conveying in addition some non-A, non-B hepatitis agent; and
- It is not necessarily typical of the UK as a whole ....<sup>328</sup>

**27.226** In view of the interest of the SHHD, it was said that Dr Forrester or Dr McIntyre would welcome the opportunity to be present at the meeting of the CSO Biomedical Research Committee on 25 September. A manuscript note on the memorandum informed Mr Tom Macdonald, the branch head, that Dr Forrester was pressing forward with getting CSO money for the proposal, with the support of colleagues.

**27.227** In a minute to Mr Macniven dated 1 October 1987, Dr Forrester stated that the Gillon/McClelland grant application had been considered, and rejected, at a meeting of the CSO Biomedical Research Committee (BRC).<sup>329</sup> Dr Forrester was present at the meeting and noted on 25 September 1987 that the Committee had rejected the application on scientific grounds, which he agreed were 'substantial'. While the Inquiry has been unable to recover a minute of the BRC meeting of 25 September 1987, the surrounding documentation makes it reasonably clear that the BRC was of the view that restricting the proposed study into surrogate markers to donors and not including the follow-up of recipients, was of little or no scientific merit: it would not provide information on the prevalence of post-transfusion NANB Hepatitis, nor would it provide information on whether the presence of surrogate markers in donors was associated with the development of post-transfusion NANB Hepatitis in recipients.<sup>330</sup> These are substantially the reasons for the view that the Follett and Dow study of September 1984 provided no basis for arriving at conclusions on the prevalence of transfusion-transmitted NANB Hepatitis or on the likely efficacy of surrogate testing in reducing the incidence of transmission of the disease.

<sup>327</sup> Minute by Dr Forrester dated 20 August 1987 [SGH.002.8079]

<sup>328</sup> Ibid [SGH.002.8079]

<sup>329</sup> Dr Forrester's minute of 1 October 1987 to Mr Macniven [SGH.002.8077]

<sup>330</sup> See, for example, the following letters to Dr W Forbes, CSO, namely, (1) letter dated 4 September 1987 by Professor C. du V Florey, Head of the Department of Community Medicine, University of Dundee [PEN.016.0167], (2) letter dated 27 October by a redacted author [PEN.016.0210], (3) letter dated 2 November 1987 by Professor Hedley, Chair of Public Health and Head of the Department of Community Medicine, University of Glasgow [PEN.016.0156]. See also, letter dated 13 November 1987 from Dr W Forbes to Dr M Smith, DHSS [PEN.016.0152]

**27.228** In his minute to Mr Macniven of 1 October 1987, Dr Forrester indicated a major interest in the formulation of the BRC's reasons for rejection of the grant application. He had asked Dr Forbes, CSO, to ensure that the minutes of the BRC decision would confirm that the reason for rejection was not that research was 'superfluous', which he noted was the SNBTS position. He also asked that announcement of the decision should be withheld until 'CSO have put their act together with DHSS Research Management Division'. He had also asked for a statement in writing of the reasons for rejection, which he anticipated would take some time to prepare. In a summary he noted that, while agreeing that the scientific evidence was incomplete, the SNBTS nonetheless maintained that their general obligation to the recipients of blood and blood products required screening to start immediately, despite its recognised drawbacks and cost; that the Health Departments, along with the NBTS, were pressing for more scientific evidence before making any decision to screen; and that the gathering of the evidence, at least in Scotland, was obstructed by the limitations of the research proposal. These limitations meant that the results of the proposed research could prove inconclusive, which was a serious objection to undertaking it. In respect of the outstanding application by the SNBTS for funds to introduce surrogate testing he stated:

[I]f there is no hurry to reach a decision ... [I] would prefer to do so when the written statement of reasons for rejection [of the Edinburgh grant application] has arrived, and when our CSO and the DHSS have reached a common stance.<sup>331</sup>

**27.229** Mr Macniven replied to Dr Forrester on 2 October 1987. He noted that the PES timetable required a decision to be reached very soon on whether to earmark funds for the SNBTS for surrogate screening to commence in the second half of 1988. He had, however, taken steps to get round the problem by registering with Finance Division that a need for NANB Hepatitis testing may emerge but that it would be premature to allocate money to the SNBTS for that purpose at that time. Mr Macniven stated in his minute:

But I am a little anxious about the timescale implied by your minute. I am very anxious indeed [that] our decision (on whether or not to put resources into NANB testing) should be properly informed by research evidence. If that evidence justifies testing, then it is very important that we should be able to find the money to start it quickly. If it does not justify testing, it is equally important that we should not have allocated money to the SNBTS for the purpose, thereby sterilising it for other uses. But I think the worst of all possible worlds is that research cannot get off the ground: I fear that, in those circumstances, we would be subjected to increasingly irresistible pressure to spend the money in any case, for the sake of improving (at any price) the safety of blood and blood products.

... [I] can well understand the general CSO disinclination to "repair" research proposals: but I hope that too much stress does not need to be placed on that principle in this case, because of the substantial patient safety/expenditure issues which are stake.<sup>332</sup>

---

<sup>331</sup> Dr Forrester's minute of 1 October 1987 to Mr Macniven [SGH.002.8077] at 8078

<sup>332</sup> Mr Macniven's minute of 2 October 1987 to Dr Forrester [SGH.002.8076]

**27.230** In his evidence to the Inquiry, Mr Macniven agreed with the suggestion that the memorandum was consistent with him keeping an open mind on the subject of surrogate testing and that, if he had been persuaded on the evidence, he would have sought to ensure that funding was available. As he put it, ‘funding should not be the obstacle’<sup>333</sup> and ‘I was very keen to make sure that funding should not be the limiting factor if the scientific/technical light turned to green.’<sup>334</sup> He explained that it would be ‘the worst of all possible worlds’ if research could not get off the ground because ‘we would be taking the decision on information which was not properly informed by research evidence’.<sup>335</sup>

**27.231** Drs Gillon and McClelland were written to on 19 November 1987 advising that their grant application had been declined.<sup>336</sup>

**1988**

### Funding for the multi-centre study in England

**27.232** On 20 January 1988 a paper was produced for the Central Blood Laboratories Authority. ‘Screening of NBTS blood donors’<sup>337</sup> proposed that the BPL should come into line with all other major fractionators of human plasma by including ALT testing in the specification of source plasma collected by blood donor centres. The drive for ALT testing was said to have been strongly augmented by manufacturers’ liability and the demands of patients to eliminate NANB Hepatitis as a sequel to treatment, with the development of severe liver disease in up to 60% of sufferers.<sup>338</sup> The paper noted that the scientific basis for introducing ALT screening of donors was far from satisfactory and that, as regards Factor VIII, the BPL was distinguished from competitors by the use of dry heat virus inactivation and the use of plasma unscreened for ALT and so outside the ‘state of the art’ practised in the USA and Europe. The BPL had a clear commercial motivation for screening which was independent of safety issues. It would be necessary if surplus products were to be sold in Europe.

**27.233** The risk that the pressure on the BPL would result in the introduction of testing prompted a reaction in the DHSS. A DHSS minute in January 1988 reveals that an application for funding for the English part of the multi-centre study into surrogate markers in donors had been refused by the DHSS Research Management Division.<sup>339</sup> The minute argued that the study should nonetheless be funded for policy reasons and noted, particularly, that all major producers of blood products now used plasma from ALT-tested blood, which put pressure on the BPL to do likewise. In addition, if the BPL was forced to introduce ALT testing of the plasma used in its products, that would involve ‘writing off’ its stockpile of plasma, worth around £40 million, and importing commercial products at a further cost of around £10 million. The author of the minute, Mr Harris, noted that embarking on the proposed multi-centre study would reduce the likelihood of pressure from haemophilia centre Directors and the Haemophilia Society to introduce surrogate screening, in that

<sup>333</sup> Day 65, page 185

<sup>334</sup> Day 78, page 33

<sup>335</sup> Ibid pages 34–35

<sup>336</sup> The Inquiry does not have a copy of the letter to Drs Gillon and McClelland advising them that their application had been refused but notes the reference to this communication in a minute dated 15 April 1988 from Dr Moir, Director, CSO [SGF.001.2059]

<sup>337</sup> Screening of NBTS Blood Donors [DHF.003.0500]

<sup>338</sup> The meaning of, and basis for, this assertion is unclear. It is a much higher figure than was otherwise reported at the time for the percentage of NANB Hepatitis patients with chronically elevated ALT levels who developed cirrhosis (ie between 10 and 20%) and may have been intended to be a reference to the percentage of patients with NANB Hepatitis who developed chronically elevated ALT levels.

<sup>339</sup> Minute dated 29 January 1988 from Mr M Harris, DHSS [PEN.016.0216]

the study might demonstrate (i) the low incidence of NANB Hepatitis carriers in the NBTS donor pool and (ii) the low utility of the ALT test. The minute concluded:

Such a study could (against all expectations) prove the need for the ALT test, even so it would then have provided scientific justification for the resulting expenditure. Even having a study in train, would give Ministers a valid reason for not being “bounced” into accepting ALT testing.

The R&D programme cannot find room for this study – cost £72,000. In view of the serious financial consequences for the HCHS [Hospital and Community Health Services] can it be exceptionally found from the HCHS central fund?

I feel that Ministers would not thank us for failing to head off this folly.

**27.234** The arguments in the minute in favour of the study were, presumably, persuasive in that funding for the English part of the multi-centre study was duly found from the relevant DHSS policy division.<sup>340</sup>

**27.235** In a minute of 14 April 1988 Dr Forrester noted that the English part of the multi-centre had received funding and commented:

From now on the tables are turned. We will have to watch what England do, because they will be first to get the relevant research data; and they are, even now, under more external pressure to institute testing for ALT. The pressure here is still evidently internal: SNBTS striving to keep up with any competition.

... [I] think we cannot help being left behind – but in this particular context, there may not be drawbacks.<sup>341</sup>

**27.236** Commenting on Dr Forrester’s minute, Dr Moir, Director, CSO, noted that he had discussed matters with Dr Jeremy Metters of the DHSS who had advised that his DHSS colleagues with policy interests felt particularly vulnerable. They were aware that there were some Scottish data on the prevalence of the problem whereas there was no comparable data in England and Wales.<sup>342</sup> Dr Moir noted:

[Dr Metters] also felt that a substantial part of his policy colleagues’ interests in funding this “research” study was that it would allow them to “play for time” in the hope that instead of ALT a more suitable screening assay could be found which would act as a marker for [NANB] Hepatitis.<sup>343</sup>

**27.237** At their meeting on 12 April 1988 the SNBTS Directors confirmed that it had been agreed not to introduce ALT testing in Scotland until it had become UK policy.<sup>344</sup> The Directors, however, wished to reserve their position in light of reports of ALT testing in at least one RTC in England and Wales.<sup>345</sup> It was noted that imported commercial products were being marked ‘ALT tested’.

<sup>344</sup> Minutes of the SNBTS Directors’ Meeting, 12 April 1988 [SNB.002.7321] at 7324

<sup>345</sup> At the next meeting of the SNBTS Directors, on 14 June, it was reported by Professor Cash that it was the intention of the Birmingham RTC to begin ALT and anti-HBc testing routinely within the next months. Minute [SNB.002.7333] at 7337 as corrected at the meeting on 27 September 1988 [SNB.002.7344] at 7345

**27.238** Studies continued to be reported that showed a low prevalence of ALT and anti-HBc in the general population. In 1988 Dr Alan Kitchen and colleagues reported on a study to determine the incidence of anti-HBc in donors at the North East Thames Regional Transfusion Centre.<sup>346</sup> In the study, 1893 donors were tested, of whom 35 (1.85%) were repeatedly positive. The authors commented that, at that time, there was likely to be very little benefit in the introduction of anti-HBc screening of blood donors. The loss of approximately 2% of available donors because of deferment would cause problems for those transfusion centres facing shortages of donors, especially those serving the Greater London Area. The costs of testing donations for the presence of anti-HBc were high and, in the prevailing financial climate, would be hard to justify. A further consideration was the need to counsel those donors found to be anti-HBc positive. Although the authors accepted that the introduction of surrogate testing might eventually be unavoidable, they believed that only a controlled prospective study would provide the necessary information to determine the significance of donor anti-HBc levels in relation to post-transfusion hepatitis, especially NANB Hepatitis, in the UK.

**27.239** At the annual meeting of the SNBTS Directors and the Scottish Haemophilia Centre Directors on 5 May 1988, Dr Forrester reported that the multi-centre study into NANB Hepatitis surrogate screening was being carried out in England and that a decision whether to introduce screening would probably wait upon its outcome.<sup>347</sup> Dr McClelland and Professor Cash were both uncomfortable with the delay involved. In effect, the funding process had excluded the SNBTS from participation in continuing research by the NBTS into the effectiveness of surrogate screening of blood donations.

### The Chiron announcement

**27.240** This was the position reached in the UK immediately before Chiron Corporation, USA, made the important announcement, on 10 May 1988, that had identified, cloned and expressed proteins from an NANB Hepatitis virus and had developed a prototype immunoassay that might lead to a screening test.<sup>348</sup>

**27.241** The announcement heralded the beginning of a transitional period between the discovery and the production of a marketable test during which surrogate testing for NANB Hepatitis remained of significant interest. The issue at this stage, in 1988, was whether it was appropriate to postpone a decision on the introduction of surrogate testing for NANB Hepatitis, using the assays then available.

**27.242** The SNBTS Directors noted the Chiron announcement, at their meeting on 14 June 1988.<sup>349</sup> Professor Cash was to enquire about the availability of the test in the UK; at that stage, he thought that 'specific NANB testing kits will be available in about 2 years'.<sup>350</sup> A subsequent letter from Ortho Diagnostic Systems Ltd, which had entered into an agreement to manufacture the test kits under licence from Chiron, advised that the kits might be available 'towards the end of 1989'.<sup>351</sup> The 1988 SNBTS PES bid, which

<sup>347</sup> Minutes of meeting of SNBTS Directors and Haemophilia Directors, 5 May 1988 [SGH.001.7505] at 7508-9

<sup>348</sup> News Release dated 10 May 1988 by Chiron Corporation [PEN.016.0290]. Dr McClelland gave evidence that 'the breakthrough, if I can use that term, that led to [the Chiron group] discovering the Hepatitis C test was dependant entirely on what was very novel technology, which I and most of my colleagues didn't know anything about at the time. You know, the sort of reverse engineering of a virus from - starting off with an antibody was science fiction, as far as I was concerned.' Day 64, page 120

<sup>349</sup> Minutes of SNBTS Directors' Meeting, 14 June 1988 [SNB.002.7333] at 7336-7337

<sup>350</sup> Note of SNBTS Directors' Meeting, 14 June 1988 [SGH.002.8034]

<sup>351</sup> Letter dated 19 July 1988 from Allan J Follett, Managing Director, Ortho Diagnostics Systems Ltd, to Professor Cash [SNB.008.3586]

appears to have been prepared in June 1988, sought funding for ALT testing in 1989–90 and funding for use of the Chiron/Ortho test in 1990–91.<sup>352</sup> In particular, PES bids for funding for testing were submitted by the CSA as follows:

- (i) 1989–90 ALT £85,000
- (ii) 1990–91 ALT £25,000; NANB<sup>353</sup> £300,000

**27.243** There was discussion of the Ortho anti-HCV test when the SNBTS Directors met on 27 September 1988.<sup>354</sup> The test had been the subject of a workshop at the International Society of Blood Transfusion Conference in July 1988. As understood by the Directors, the availability of the test was not imminent and the data presented had been inconclusive. The antibody was a late-developing one which would present similar problems in relation to the ‘window’ between infection and the production of measurable antibodies, as was the case with HIV. In the SNBTS Directors’ view, ALT remained the earliest available indicator of infection. Notwithstanding the Chiron discoveries, therefore, there was likely to be a period, of indefinite duration, in which surrogate testing for ALT or anti-HBc remained a relevant and material issue for the SNBTS. The Directors agreed not to plan any medium-term policy on the basis of the successful introduction of Chiron technology and that ALT would remain the test of choice in the meantime.

**27.244** At the end of 1988, however, the SNBTS Directors continued to take the view that Scotland should not commence surrogate testing, pending the outcome of the UK study. At their meeting on 13 December 1988, Dr Wagstaff informed the Directors that the DHSS had funded three centres to carry out a study of ALT technology and of anti-HBc screening. Professor Cash confirmed that the Scottish Directors would not commence surrogate testing ‘until the Department of Health and the SHHD supported and funded the project’, which would be a task for the soon-to-be-formed UK blood transfusion services’ Advisory Committee on Transfusion Transmitted Diseases (ACTTD).<sup>355</sup> The issue would also engage the Advisory Committee on the Virological Safety of Blood (ACVSB). The topic had moved into a new phase, with advice being taken from duly constituted expert bodies.

**27.245** Dr Gunson had, early in 1988, discussed with Dr McClelland and Dr Pickles the formation of a UK group to determine policy with respect to transfusion-transmitted diseases.<sup>356</sup> In the event, two groups were formed. The ACTTD was a UK BTS group on transfusion-transmitted diseases. The ACVSB was a DoH group on the virological safety of blood. The ACVSB had a wider remit than blood transfusion medicine, embracing transplantation and other aspects of disease transmission. It was a UK advisory committee and included Scottish members. The establishment of the ACVSB and the ACTTD and the groups’ initial discussions relating to the introduction of anti-HCV testing in the aftermath of Chiron’s discoveries, are described in Chapter 31, *The Introduction of Screening of Donated Blood for Hepatitis C*. In this chapter, it is necessary to trace only the fate of the investigations into the use of surrogate testing that continued into the period from 1989 onwards.

<sup>353</sup> This appears to be a reference to the Chiron/Ortho anti-HCV test

<sup>354</sup> Extract from minutes of the SNBTS Directors Meeting, 27 September 1988 [SGH.002.8027]

<sup>355</sup> Minutes of SNBTS Directors’ Meeting, 13 December 1988 [SNB.002.7350] at 7353

<sup>356</sup> Minutes of ACTTD on 24 February 1989 [SNB.006.1975]; Dr McClelland’s Witness Statement [PEN.017.2491]

**1989**

**27.246** The ACTTD had among the terms of reference agreed at its first meeting on 24 February 1989: 'To consider the epidemiological, clinical and laboratory aspects of diseases which may be transmitted by the transfusion of blood and blood products.'<sup>357</sup>

**27.247** The continuing three-centre study of ALT technology and anti-HBc screening in England and Wales was also within the group's remit.

**27.248** At that meeting, Dr Contreras (North London RTC) outlined the results of the study to that date. Notwithstanding the decisions on funding already discussed, research continued in Scotland. Dr Mitchell reported on the study of 5000 donations in Glasgow, in which 2.8% of donors had elevated ALT levels. With respect to anti-HBc tests, in a separate study 17 out of 2000 donations were found positive, of which 15 results were reproducible. Professor Cash reported that the methodology for ALT testing and follow-up had been examined in Scotland and that a standardised method had been agreed. This would be available to the RTCs if the general introduction of ALT testing was agreed.<sup>358</sup> It was again agreed that there should be no recommendation to institute ALT testing until the current study in England was completed.<sup>359</sup> It was noted, however, that there was a degree of inevitability about the introduction of the test, which was required by regulatory authorities in other countries to determine the acceptability of fractionated plasma products. That would be discussed with the BPL in the near future.<sup>360</sup> At this stage, therefore, the ACTTD was resolved to continue research into surrogate testing, but with acknowledgement that external marketing considerations would come to drive the agenda (that having been recognised to be the case for some time).

**27.249** In the meantime, steps had been taken to implement the decision of the UK health ministers, originally proposed the year before, to set up the ACVSB. The decision was intimated in a letter of 8 March 1989 sent out by Dr E Harris.<sup>361</sup> The ACTTD and other committees would report through the ACVSB, which would provide formal scientific advice to the UK Government and its agencies. The terms of reference of the ACVSB were:

To advise the Health Departments of the UK on measures to ensure the virological safety of blood, whilst maintaining adequate supplies of appropriate quality for both immediate use and for plasma products.<sup>362</sup>

**27.250** The ACVSB became the main advisory committee to the UK Government on whether surrogate testing of blood donors for NANB Hepatitis and screening of donors for Hepatitis C should be introduced. The first meeting of the group took place on 4 April 1989 under the chairmanship of Dr Harris.<sup>363</sup> The intention was that the next meeting would concentrate on viral hepatitis.

<sup>357</sup> Meeting minutes [SNB.006.1975], Terms of Reference [SNB.006.1923]

<sup>358</sup> Meeting minutes [SNB.006.1975] at 1978

<sup>359</sup> Repeating the position of the SNBTS Directors on 13 December 1988. See paragraph 27.242

<sup>360</sup> The interests of the NBTS and SNBTS were not necessarily the same. In each case the safety claims for imported products based on screening were relevant. However, in foreign markets regulation had an impact and this appears to have affected the BPL and to some extent the PFC rather than the Blood Transfusion Services as such.

<sup>361</sup> Letter from Dr Harris to Dr Perry dated 8 March 1989 [SNF.001.1263]

<sup>362</sup> Terms of Reference [SNB.001.9366]

<sup>363</sup> Meeting minutes [SNF.001.1219]

**27.251** The multi-centre study of ALT and anti-HBc testing, funded by the DHSS (see paragraphs 27.230–27.233), and coordinated by Dr Gunson, had proceeded with surrogate test trials, though impending developments relating to the Chiron discoveries were anticipated. Progress was reported in a paper subsequently submitted to the ACVSB at its second meeting on 22 May 1989.<sup>364</sup> The paper (ACVSB 2/7) stated:

This study (supported by the Health Departments) is being co-ordinated by Dr Gunson on behalf of the UKBTS. It is too early to report on this yet, but all the samples have now been collected and screened for ALT and anti-HBc. Much of the follow-up has been done, but this is not yet complete. It is hoped that in June a review of the study will take place although conclusions cannot be drawn until the results of the Chiron tests are known.<sup>365</sup>

**27.252** The paper gave up-to-date information on Chiron's progress as published, including information on the cloning of cDNA and the development of a specific assay for NANB Hepatitis. The paper concluded:

At present there does not appear to be any urgent need to introduce routine surrogate testing for NANB hepatitis among voluntary blood donors in the UK in respect of public health.

The position should be reconsidered by this Committee [the ACTTD] when the results of the UKBTS NANB study are available .... The availability of the Chiron test will help with interpretation of the data obtained. The Chiron test may also make surrogate testing obsolete ....<sup>366</sup>

**27.253** Professor Zuckerman's Taipei paper was also before the ACVSB; it continued to present the possibility of more than one agent of transmission of NANB Hepatitis. He commented that several 'non-specific' (surrogate) tests had been recommended for screening units of blood, until specific tests became widely available for NANB Hepatitis. Of these, the non-specific indicator which had received most attention was said to be ALT levels in blood donors. Several studies had shown that the risk of post-transfusion NANB Hepatitis was directly related to the ALT level of the donor. However, lack of sensitivity and the variability of ALT levels with age, sex, alcohol use and geographical region were factors. His view was that ALT levels would therefore not be useful as a surrogate marker of NANB Hepatitis.<sup>367</sup>

**27.254** The minute of the meeting of the ACVSB on 22 May 1989 noted that:

The Department would keep the issue of testing under review. The use of Chiron or surrogate testing would be influenced by Chiron data once released; MRC might be asked to consider. Members regarded the matter to be a priority.<sup>368</sup>

**27.255** At this stage, it was the consistent position of both the ACVSB and the ACTTD that surrogate testing for NANB Hepatitis should not be introduced by the transfusion services before Dr Gunson's study had been completed.

<sup>366</sup> Ibid [SNB.001.9483] at 9484

<sup>367</sup> Taipei Paper [SNB.001.9490]

<sup>368</sup> Meeting minutes [SNB.001.9416] at 9418

**27.256** The minutes of the next meeting of the ACVSB, on 3 July 1989, record the Advisory Committee's understanding that the results of Dr Gunson's NBTS study of ALT and anti-HBc testing had shown that raised ALT levels were identified in 25% of the donors sampled.<sup>369</sup> Members expressed concern that this type of study 'revealed nothing of specificity'. The figure of 25% appears to have reflected the information made available at the meeting. It was not a correct indication of the proportion of donors who would have been rejected on the grounds of elevated ALT. In subsequent reports, the average was given as 3.2%, with results from individual centres of 3.06%; 4.56% and 1.97% (see, for example, the entries for 3 November 1989 below).<sup>370</sup>

**27.257** Dr Gunson's paper for the Council of Europe's Committee of Experts in Blood Transfusion and Immunohaematology, analysing replies from ten countries to a questionnaire on NANB Hepatitis, was also available.<sup>371</sup> As already noted, routine ALT testing of donations was carried out in four countries: Germany, France, Malta and Switzerland. France also routinely performed anti-HBc testing. Denmark, Norway, the UK and France were undertaking studies to determine their policies. Members of the ACVSB supported the Council of Europe view that anti-HCV testing alone was not sufficient to eradicate post-transfusion hepatitis.<sup>372</sup> Members cautioned against the overtly commercial stance of test manufacturers. It was reported that first time recipients of Factor 8Y had been screened by the Chiron test and had shown no positive results. Further study of stored sera from haemophilia patients was advocated. Dr Phillip Mortimer, Public Health Laboratory Service (PHLS), thought that there was a persuasive case that the Chiron test results were reliable. The outcome was that the (new) Chairman, Dr Metters, considered that all the available data should be compiled and provided for the next meeting. Members were asked to forward all contributions on NANB Hepatitis to the Committee's secretariat.<sup>373</sup>

**27.258** On 3 November 1989 Dr Gunson produced the final report of the multi-centre study in England and Wales into surrogate markers for NANB Hepatitis in donors.<sup>374</sup> The study was carried out between September 1988 and April 1989, during which time a total of 9741 blood donors at the North London, Bristol and Manchester RTCs were tested for elevated ALT and the presence of anti-HBc. In summary, the report stated:

- Taken overall, 3.2% of donors would have been rejected for raised ALT and 0.63% for anti-HBc seropositivity. However, if only donors with a raised ALT on two successive samples were rejected, the number would have been reduced to 1.1%. A 'disturbing finding' was the variability of ALT testing in the three centres.
- It was difficult to conclude how many of the donors with a raised ALT, or who were seropositive for anti-HBc, might have transmitted NANB Hepatitis. To determine that, a prospective study would have to be performed.
- However, it was evident that the ALT test was non-specific since the correlation with alcohol intake and obesity was striking. Similarly, the significance of a positive anti-HBc result was unknown.

<sup>369</sup> Meeting minutes [SNB.001.9513] at 9514

<sup>370</sup> See paragraph 27.257

<sup>371</sup> See paragraph 27.63

<sup>372</sup> Meeting minutes [SNB.001.9513] at 9514

<sup>373</sup> Dr Metters succeeded Dr Harris as DCMO and chairman of the ACVSB on 31 July 1989: Minute of ACVSB meeting of 3 July 1989 [SNB.001.9513]

<sup>374</sup> Appended to the agenda for the ACVSB meeting on 6 November 1989 [SNF.001.1383] at 1387. A further, fuller, report was produced in April 1990 [PEN.016.0075] and a formal report was published in the journal *Transfusion Medicine* in 1992 [PEN.017.0831]

- Following the introduction of the anti-HCV test the only justifications for routinely performing the ALT and anti-HBc tests were:
  - The possibility that ALT (in particular) would identify a 'window' of infectivity prior to seroconversion to anti-HCV.
  - The possibility that anti-HCV identified only one of a number of viruses which caused NANB Hepatitis.
- The introduction of other specific viral markers and increased sensitivity of the anti-HCV test might in due course render the subject of surrogate testing of academic interest. Meanwhile, the desirability of introducing these tests remained an issue of health economics.<sup>375</sup>

**27.259** Dr Gunson's report was considered at the fourth meeting of the ACVSB on 6 November 1989.<sup>376</sup> Dr Gunson drew members' attention to the non-specificity of ALT testing brought out in the report. He also reported discussion at a meeting in Rome sponsored by Chiron. The debate on use of the Chiron test is discussed in Chapter 31, *The Introduction of Screening of Donated Blood for Hepatitis C*. So far as surrogate tests for ALT and anti-HBc are concerned it is reported that Dr Gunson commented that there was a question mark hanging over their status. After discussion of the Chiron test, it was the feeling of the Advisory Committee that there was no case for using surrogate tests for NANB Hepatitis. That was largely the end of the issue of general surrogate testing in the UK as consideration turned instead to the evaluation and eventual introduction, on 1 September 1991, of the Chiron/Ortho test for antibody to Hepatitis C.

### *UK Postscript–1990s*

**27.260** Apart from sporadic references to surrogate screening for specific purposes, there was no independent consideration given in Scotland at this time to the introduction of surrogate testing, consistent with the decision that the procedures would not be introduced before the DHSS and the SHHD, on the advice of the expert advisory bodies, supported and funded them.<sup>377</sup> On 12 March 1990, Mr David McIntosh (General Manager, SNBTS) wrote to Dr McIntyre (SHHD) on the subject of ALT donation testing.<sup>378</sup> Subject to advice from the ACVSB, Mr McIntosh's understanding was that neither the SNBTS nor the NBTS would be introducing ALT testing for the time being and that neither the SHHD nor the DoH recommended that such testing should be introduced. Equally, however, it was anticipated that there could be a need to start new testing procedures, probably including ALT testing, in conjunction with another test or tests. There was a possibility of having to take rapid steps during the course of the summer. Consistent with that possibility in July 1990, a revenue bid for funding for ALT and anti-HBc testing was submitted by the SNBTS for 1991–92.<sup>379</sup> It was, however, considered highly unlikely that ALT and anti-HBc tests would be introduced into routine practice in the forthcoming financial year and the provisions were carried forward to the next year. In the event, the introduction of HCV testing superseded the need for provision of surrogate testing.

<sup>375</sup> Report (ACVSB version) [SNF.001.1383] at 1388–1389

<sup>376</sup> Meeting minutes [SNB.001.9563] at 9566–9567

<sup>377</sup> See Preliminary Report paragraphs 9.188 and 9.189

<sup>378</sup> Letter [SGH.002.7958]

<sup>379</sup> Public Expenditure Survey, bid number PES90 1.2.a.ii [SNB.002.7426] at 7433. The date for the bid is taken from the Agenda [SNB.002.7404] for the SNBTS management meeting of February 1991.

**27.261** The NBTS and the SNBTS were awaiting the outcome of the Ortho anti-HCV trial in progress before taking a decision but the broad policy issues had by this time been referred to the ACVSB. It was that body's advice that, in November 1989, effectively brought to an end the active consideration of general surrogate testing of blood donations and blood donors in the UK. By that time the practice had already been adopted in the USA and in some European countries.

**27.262** On 8 February 1990 the American Association of Blood Banks, the American Red Cross and the Council of Community Blood Centres issued a joint statement: 'Guidelines for planning the implementation of anti-HCV testing of blood and components for transfusion'.<sup>380</sup> The statement recommended that ALT and anti-HBc screening of blood donations should continue until it could be demonstrated that NANB Hepatitis agents other than the Hepatitis C virus were not a significant cause of transfusion-associated hepatitis.

**27.263** In this respect, however, practice in the USA does not provide guidance. Pragmatic considerations dictated the continuance of established practice in the USA and there was nothing to suggest that the decision had been driven by new insights into the efficacy of surrogate testing.

**27.264** Professor Cash drew the Inquiry's attention to evidence that consideration had been given in England in the early- and mid-1990s to the ALT testing of plasma sent to the BPL for the manufacture of albumin and intravenous immunoglobulin.<sup>381</sup> While it is unclear whether ALT testing of plasma for the BPL was actually introduced in England,<sup>382</sup> it appears that the consideration given to such testing was based solely on economic factors (as such testing would allow excess fractionated products manufactured by the BPL to be sold abroad rather than destroyed) and it was expressly disavowed that the use of ALT testing of plasma that was to be used for the manufacture of blood products implied any safety benefit.<sup>383</sup>

### Studies conducted after the Ortho anti-HCV test became available

**27.265** It is convenient at this stage to consider various studies that were carried out after the Ortho anti-HCV test became available. In short, while studies indicated that ALT screening of donors is likely to have materially reduced the incidence of transfusion-transmitted NANB Hepatitis, it is not possible to quantify that reduction with any degree of accuracy. Furthermore, the results of these studies were not available until after anti-HCV screening had been introduced in the UK, in September 1991.

**27.266** In common with the rest of the UK, Scotland introduced anti-HCV screening on 1 September 1991. In the first six months of testing the prevalence of HCV infection among blood donors was 0.088%.<sup>384</sup> Of the 159 HCV positive donors identified, 151 responded to the invitation for further counselling and follow-up and 59% (89) of these

<sup>380</sup> Guidelines for Planning the Implementation of Anti-HCV Testing of Blood and Components for Transfusion [SNB.001.9825]

<sup>381</sup> Additional statement from Professor Cash [PEN.017.1885] at 1889–1890

<sup>382</sup> See the supplementary statements by Professor Cash [PEN.017.2635], Dr Foster [PEN.017.2636] and Dr Perry [PEN.017.2777]

<sup>383</sup> See, for example, the discussion in the September 1994 revised report of the NBS working group on ALT testing of plasma [SGH.008.7021] and the discussion of that report at the third meeting of the Advisory Committee on the Microbiological Safety of Blood and Tissues for Transplantation (the successor committee to the ACVSB) on 29 September 1994 [DOH.001.0021] at 0026–0028

<sup>384</sup> Crawford et al, 'Prevalence and epidemiological characteristics of hepatitis C in Scottish blood donors', *Transfusion Medicine*, 1994; 4:121 [PEN.002.0582]

151 HCV-positive donors had ALT levels above the upper limit of normal.<sup>385</sup> This was not a random sample, however, but a self-selected group and, importantly, it could not be inferred that excluding all donors with elevated ALT (ie above the upper limit of the laboratory's reference range) would have prevented 59% of cases of transfusion-related Hepatitis C infection. As Dr Gillon explained:

[T]he vast majority of the carriers of Hepatitis C were at levels below the cut-offs that were proposed. And looking at this 59[%] figure, that was based on a relatively low cut-off – well, in Edinburgh it was 40 units per litre. It was probably the same elsewhere, which is not what we would have used in practice.<sup>386</sup>

**27.267** Once more sensitive HCV tests became available, Dr Dow and colleagues tested samples stored from his study undertaken between 1980 and 1984.<sup>387</sup> In the study, a total of 54 donations – 50 from prison donors and four from other donors – were found to have ALT values in excess of 2.5 times the upper limit of normal. Thirty-two of these samples were stored frozen and tested with various HCV tests including the Polymerase Chain Reaction (PCR) test. Twenty-one of the 32 stored samples (65.6%) were positive on PCR testing. This was a relatively high proportion on any view. However, it probably reflected the higher incidence of Hepatitis C in the prison population in the first half of the 1980s and cannot be held to be representative of the correlation between surrogate markers and HCV infection generally.

**27.268** The 1989 evaluation study of the first generation Ortho anti-HCV test by Dr Dow and colleagues should also be noted.<sup>388</sup> Granted the insensitivity of this test, it is interesting nevertheless to note that only 15 of the 2745 donations tested (0.54%) were positive on initial screen test and, of these, 13 were repeatedly reactive on repeat testing in duplicate. All 2745 donations had been tested for ALT levels in the earlier exercise in 1987 and 1988. Only one of the 15 initial screen positive donations had an abnormal ALT level.

**27.269** Later studies have indicated that, in some countries at least, surrogate testing was more effective in screening out HCV from donor blood than the UK study and, indeed, the early TTV and NIH studies in the USA had suggested it might be. Once anti-HCV tests became available, the NIH and TTV study groups tested stored sera collected from a relatively small number of patients in whom NANB Hepatitis had developed after transfusion.<sup>389</sup> The NIH group estimated that in their study ALT and anti-HBc screening would have detected approximately one half of the anti-HCV positive donors involved in the transmission of hepatitis.<sup>390</sup> The TTV group reported that just over 70% of cases of post-transfusion Hepatitis C in their study were associated with the presence of surrogate markers in donors.<sup>391</sup> The tests used were of the first generation, however, and lacked sensitivity, as discussed in Chapter 31, *The Introduction of Screening of Donated Blood for Hepatitis C*.

<sup>385</sup> Ibid [PEN.002.0582] at 0583. Dr Dow gave evidence that 'we were aware that 25% of all HCV confirmed positives were anti-HBc reactive', although it is not clear what the source of that information was: Statement [PEN.017.1925] at 1930

**27.270** Another large US study (carried out in Baltimore and Houston) found that the introduction of surrogate testing had reduced by 60% the risk of patients developing anti-HCV.<sup>392</sup> In particular, of 912 patients undergoing cardiac surgery who received transfusions between April 1985 and September 1986, at a time when donors were not screened for surrogate markers, 35 patients seroconverted<sup>393</sup> to anti-HCV (an attack rate of 3.84%). Of 976 patients who received transfusions after surrogate testing was introduced in October 1986, only 15 seroconverted to anti-HCV (an attack rate of 1.54%).<sup>394</sup> In interpreting the data from this study, however, one must bear in mind that, even without the introduction of surrogate testing in the USA, rates of post-transfusion hepatitis may have reduced as a result of the HIV exclusion measures taken from 1984 onwards. In his evidence to the Inquiry, for example, Dr McClelland noted that the authors of the Canadian paper discussed below had observed that there had been a similar reduction in the prevalence of post-transfusion hepatitis in Canada over the same period, in the absence of the introduction of surrogate testing.<sup>395</sup>

**27.271** That Canadian study into post-transfusion hepatitis was carried out between 1988 and 1992.<sup>396</sup> In one group of patients who received blood transfusion, units which were positive for NANB Hepatitis surrogate markers were withheld, while in the other group of patients such units were not withheld. Samples from 2277 patients in the group in which units positive for surrogate markers were not withheld were tested retrospectively when the anti-HCV test became available. It was found that 10 patients (0.44%) had developed Hepatitis C. Of 2311 patients in the group in which units positive for surrogate markers were withheld, only three patients (0.13%) developed Hepatitis C.<sup>397</sup> The authors concluded that withholding blood containing surrogate markers reduced by 70% the rate of post-transfusion HCV in their study.<sup>398</sup> Interpreting the study, however, may be complicated by the fact that Canada introduced screening of donors for anti-HCV in May 1990, part way through the study.<sup>399</sup>

**27.272** In Finland, a prospective study was carried out between 1987 and 1989 which aimed, as one of its goals, to determine the predictive value in donor screening of surrogate marker candidates.<sup>400</sup> Stored samples were tested with first generation anti-HCV tests once these tests became available. Six of the 145 recipients (4.14%) of at least one unit of blood with raised ALT levels<sup>401</sup> developed NANB Hepatitis (as measured by elevation of ALT levels post-transfusion). That figure is in contrast to five of the 540 recipients (0.93%) who received only blood with normal ALT levels.<sup>402</sup> The positive predictive value of ALT (the percentage of cases of NANB Hepatitis among all recipients of blood with elevated

ALT) was only 4.1%.<sup>403</sup> No correlation was found between the presence of anti-HBc in donors and the development of NANB Hepatitis in recipients.<sup>404</sup>

## Discussion

### *Prospective study of post-transfusion NANB Hepatitis in the UK*

**27.273** At any time during the period 1981–88, the introduction of surrogate testing for NANB Hepatitis virus infection of donor blood, or of blood components and products, would have involved significant expenditure. It would have been considered a matter of such importance at the time to have required ministerial approval.<sup>405</sup>

**27.274** Ministerial decisions might have involved political considerations and almost certainly would have required the balancing of competing demands for funding. Before that stage was reached, however, the preliminary course that had to be negotiated, before ministers were consulted, would have included scientific and medical input and administrative discussions and decisions.

**27.275** The benefit of surrogate testing would have depended on the efficacy of the test or tests used in identifying blood and blood components that carried risk for the recipient. A decision to introduce testing would have required information and advice on a number of interrelated factors, including:

- The prevalence of infection in the relevant donor population or populations.
- The sensitivity of the tests as applied to those people (a measure of the efficiency of the test in identifying people with the target disease).
- The specificity of the tests as applied to those people (a measure of the efficiency of the test in identifying people without the target disease).
- The incidence of post-transfusion hepatitis.
- The clinical significance of post-transfusion NANB Hepatitis.
- The impact of testing on the donor population or populations.
- The cost/benefit balance found on analysis of all relevant information.

**27.276** The issue of whether or not to introduce surrogate testing of blood donors for NANB Hepatitis was never put to ministers and the reasons for that changed through the 1980s. This section deals with events at the beginning of the period that had long-lasting consequences. Those events, involving discussions within scientific and medical advisory groups, prevented research into the first three factors listed above: the prevalence of infection and the sensitivity and specificity of available tests.

**27.277** The MRC report of the Maycock Group study into post-transfusion hepatitis carried out between 1969 and 1971, was published in 1974.<sup>406</sup> As previously noted, it carried the authority of Professor Zuckerman and Professor Sherlock in addition to that of Sir William Maycock. The findings were influenced by the approach adopted: elevated ALT values alone were not regarded as providing sufficient evidence of hepatitis. The

<sup>403</sup> Ibid [PEN.017.1763] at 1765

overall incidence of icteric and anicteric hepatitis (that is, hepatitis with or without clinical jaundice) was calculated to be 1% – lower than in other countries, at least in part due to the factors stipulated by the authors as prerequisites of diagnosis. A range of factors that might have influenced the result were considered in the discussion part of the paper but none of them was thought to undermine the overall assessment. The MRC study was regarded for many years as proof that the incidence of post-transfusion NANB Hepatitis in the UK was not a significant problem whereas, when properly analysed and having regard to the limitations of the study, it could offer no such assurance.

**27.278** As was the case with Dr Rosemary Biggs' report of the incidence of episodes of jaundice among haemophilia patients treated with blood products, also published in 1974,<sup>407</sup> the data discussed in the MRC report were collected before the existence of NANB Hepatitis was postulated. The seminal article by Alfred Prince and others was published on 3 August 1974.<sup>408</sup> Dr Biggs' data were drawn from returns from Haemophilia Centres for the period 1969 to 1971 and reflected the perception at that time that jaundice was the appropriate focus for assessment of the incidence of transmitted virus infection.<sup>409</sup>

**27.279** When the MRC ad hoc meeting took place on 12 February 1979<sup>410</sup> to discuss, amongst other matters, growing anxiety about the threat of NANB Hepatitis, it was recognised that ALT (referred to by its alternative name, SGPT in the minute) testing could be a useful pointer to NANB Hepatitis infection. The views of Dr Tom Cleghorn and Professor Sherlock that post-transfusion hepatitis 'must now be rare' were countered by Professor Zuckerman's observation that much NANB Hepatitis might be anicteric and might progress to chronic liver disease, however mild the initial infection. It is also clear that Sir William Maycock recognised that there was a lack of data on the prevalence of post-transfusion hepatitis. His proposal that a survey of post-transfusion hepatitis be set up was, however, rejected. The prevailing view was that until there were specific markers, a survey of post-transfusion hepatitis was not justified.

**27.280** Having regard to the published data from 1974, the effect of the decision, so far as the MRC was concerned, was that other research concerning viral hepatitis should proceed in the absence of relevant data about the prevalence of NANB Hepatitis in the UK. Dr McClelland's evidence to the Inquiry that the report of the 1974 MRC study did not, in his view, provide the information required, is accepted as accurate generally.<sup>411</sup>

**27.281** The outcome of the meeting of 12 February 1979 included a decision to set up the Working Party on Post Transfusion Hepatitis which met on 14 February 1980.<sup>412</sup> Its agreed functions included investigations to assess the incidence of NANB Hepatitis in the UK, particularly as associated with blood transfusion, the characterisation of the agent of transmission and the development of diagnostic tests. There was discussion of the intelligence available to the participants about cases of NANB Hepatitis. Against that background, Dr McClelland who to the other members of the Working Party was then a

<sup>412</sup> Meeting minutes [PEN.017.1710]

colleague without an acknowledged reputation in developing and directing large complex studies, suggested that a multi-centred study of transfusion-associated NANB Hepatitis might be sponsored by the Working Party. The minute of the meeting is rather perplexing in that, on the one hand, it noted that it was agreed that Dr McClelland's proposal should be deferred until candidate laboratory tests were available (an agreement that he did not remember)<sup>413</sup> and, on the other hand, it records agreement that there should be epidemiological surveys to assess the size of the problem in relation to blood transfusion. The minute also reported that MRC studies had already received a grant for research into the incidence, epidemiology and clinical features of NANB Hepatitis.<sup>414</sup>

**27.282** Dr McClelland clearly did not consider that he had been precluded from developing his proposal and discussed it with the SNBTS Directors on 23 June 1981 before presenting a draft protocol for a multi-centre study to the MRC Working Party on 25 June 1981.<sup>415</sup> It is not necessary to resolve the questions that arise from the minute of 14 February 1980; what happened at the meeting on 25 June 1981 is of greater significance. Significantly, as recollected by Dr McClelland, Professor Zuckerman insisted that a study into post-transfusion hepatitis had already been carried out (a reference to the MRC study reported in 1974) and 'it didn't need to be done again'.<sup>416</sup> The minute of the meeting noted that Professor Zuckerman commented on the earlier study, noted that the sera collected were available for evaluation of candidate tests for NANB Hepatitis and said of Dr McClelland's proposal: 'A careful evaluation of the need for such a project should be carried out before the Working Party could recommend to the MRC that a fresh study should be sponsored.'<sup>417</sup> Professor Zuckerman left the meeting before the discussion was concluded. The remaining members of the Working Party decided that Dr McClelland's proposals could be reconsidered later. They clearly believed that the group had a future. However, the MRC Working Party did not meet again and the prospect of an MRC sponsored study along the lines proposed by Dr McClelland disappeared.

**27.283** The initiative passed to the transfusion services' Working Party on Transfusion Associated Hepatitis which, as discussed above, met on 27 September 1982 and on three occasions in 1983 before lapsing and being reconvened on 24 November 1986. While Dr McClelland had continued to advocate a large-scale prospective study into NANB Hepatitis in the UK when the Working Party met in 1982 and 1983, by the time the Working Party was reconvened in late 1986 the view of the members was that a prospective study was impracticable on the grounds of both cost and the requirement for a large sample group.

**27.284** As more fully set out above, the view of the Scottish and English transfusion services in the late 1980s (and which was supported at various times by officials in the SHHD and the DHSS) remained that it was not feasible to carry out a large-scale prospective study of NANB Hepatitis and that, instead, there should be a limited study into the incidence of surrogate markers in donors. Such a study would not include the follow-up of recipients and thus would be of little or no assistance in determining the efficacy of surrogate screening in reducing the incidence of post-transfusion NANB Hepatitis.

<sup>415</sup> Meeting minutes [PEN.017.1478]; draft protocol [PEN.017.1486]

<sup>416</sup> Day 63, page 66

<sup>417</sup> Meeting minutes [PEN.017.1478] at 1480

**27.285** Despite the best efforts of Dr McClelland, no sufficiently large-scale prospective study was ever carried out on a coordinated basis to determine the likely prevalence of post-transfusion NANB Hepatitis in the UK. Without such a study having been carried out it was, and remains, difficult to come to an informed view on the likely prevalence of post-transfusion NANB Hepatitis in the UK generally and in Scotland in particular.<sup>418</sup>

**27.286** In his oral evidence Professor Leikola commented, with reference to the later 1980s:

I think that what was regrettable was that no ... large study was performed in the UK in order to find out what would be the value of especially ALT, both in recipients of blood and donors of blood .... We [in Finland] did not introduce ALT testing before our study was done ....<sup>419</sup>

**27.287** If he had a criticism of events in Scotland, it related to the failure to carry out a prospective study into post-transfusion NANB Hepatitis involving the follow-up of recipients (in the UK as a whole), rather than the failure to introduce surrogate testing.<sup>420</sup>

**27.288** However, in considering Professor Leikola's criticism a number of matters ought to be borne in mind. The first is that the Finnish study, 'Post-transfusion hepatitis after open-heart surgery in Finland – a prospective study' states that it was carried out between 1987 and 1989, and the second is that the Finnish Red Cross Blood Transfusion Service charged the hospitals for their products and services and could, therefore, finance the study themselves. The SNBTS was dependant on funding from the SHHD or other bodies for such a study, and that had a material effect on its ability to carry it out. Professor Leikola indicated that the catalysts for the Finnish study (which started in December 1987) were the decision made in the USA in 1986 to introduce surrogate testing and the discussions at the Council of Europe in 1987. The Council's Committee of Experts on Blood Transfusion and Immunohematology had not then recommended the introduction routinely of non-specific tests for evidence of NANB Hepatitis infectivity of blood donors but had indicated that '[i]ndividual countries would have to assess the situation locally and decide on the appropriate action to take'.<sup>421</sup> By March 1987 the SNBTS Directors had agreed to recommend to the SHHD that surrogate testing for NANB Hepatitis should be implemented with effect from 1 April 1988 as a national development requiring strictly new funding. In their letter of 4 July 1987 to *The Lancet*, entitled 'Testing blood donors for (NANB) Hepatitis: irrational, perhaps, but inescapable' they explained why they considered the introduction of surrogate testing, despite the absence of relevant data, to be 'virtually inescapable'. In particular, they adverted to forthcoming legislation that would provide for strict liability for harm caused by products unless all known measures had been taken to avoid the risk, to the possibility that such testing would reduce the level of infectivity of pooled plasma products and to consumers' wishes to be supplied with 'NANB tested' products, in light of the fact that commercial manufacturers were now doing such testing and would be likely to market their products as being safer. Haemophilia Directors had unrestricted clinical freedom to opt either for NHS fractionated products or commercially fractionated products. Had surrogate testing been introduced then blood used for blood products, blood components and whole blood would have been screened.

<sup>418</sup> This is of continuing significance in relation to estimates of HCV prevalence at the present time: see Chapter 3, *Statistics*.

<sup>419</sup> Day 71, pages 61–62

<sup>420</sup> Ibid page 63. For the Finnish study, see Ebeling et al, 'Post-transfusion hepatitis after open-heart surgery in Finland – a prospective study', *Transfusion Medicine*, 1991; 1:103–108 [PEN.017.1777]

<sup>421</sup> Council of Europe: Extract from the report of the Committee of Experts on Blood Transfusion and Immunohaematology, 19–20 May 1987 [SNB.001.9445] at 9450

**27.289** It is regrettable that Dr McClelland's proposals in the early 1980s were dismissed and that they were not taken up by others. Whilst the results of a large scale prospective study might not have led to the introduction of surrogate testing, data about the prevalence of NANB Hepatitis and the likely efficacy of surrogate testing in reducing the incidence of post-transfusion NANB Hepatitis would have led to more informed decision making. In addition, a library of samples might have been available for preservation to use in subsequent research into the Chiron anti-HCV test. In short, there were adverse long-term consequences of the decisions made by the wider scientific and medical community, first, not to follow the initial suggestion of Sir William Maycock in 1979 and, secondly, not to follow Dr McClelland's proposals in the early 1980s. However, it must be borne in mind that in Finland, despite the existence of the small 1979 study, a new, larger study was considered necessary in 1987 in consequence of the international developments described above and the effect of the AIDS risk in 1983 and 1984 on donor selection criteria. Had the SNBTS undertaken a study in 1987, as occurred in Finland, it is unlikely that it would have been completed before May 1988, when Chiron announced that they had identified, cloned and expressed proteins from an NANB virus and had developed a prototype immunoassay that might lead to a screening test. According to the Directors' letter in *The Lancet*, the study would produce no 'answer' for three to four years.

#### The administrative context

**27.290** The ultimate responsibility for deciding whether surrogate testing should have been introduced lay with the UK Government.<sup>422</sup> The Secretary of State for Scotland had cabinet responsibility, but ordinarily the junior Scottish minister, whose remit at the relevant time included Scottish health matters, would have been involved before an issue was referred to the Secretary of State. The minister would have acted on advice received from appropriate committees and from officials including, in particular, SHHD medical officers. However, apart from issues raised at ministerial level in the first place, it was for SHHD administrators to decide what issues should be referred to ministers for decision. In that context, there could be a material difference in approach depending on whether or not positive action was proposed.

**27.291** In the SHHD, the issue of surrogate testing was dealt with on a day-to-day basis by Dr Forrester, Senior Medical Officer, and Dr Archibald McIntyre, Principal Medical Officer. On occasion Dr Scott, DCMO, was also involved in considering the issue. Dr Macdonald, CMO, said in oral evidence that he was kept informed of the issue.<sup>423</sup> On the administrative side of the SHHD, surrogate testing was dealt with at a day-to-day level by Mr Alexander Murray, Senior Executive Officer, and by Mr Macniven, Assistant Secretary. On occasion, the issue reached the level of Mr Hugh Morison, Under Secretary.<sup>424</sup>

**27.292** In his evidence to the Inquiry Mr Macniven agreed that the introduction of a new screening test, such as surrogate screening with its significant financial implications, would have required ministerial approval. He was asked whether a decision not to introduce a screening test, in particular one that was recommended by the SNBTS Directors, was also a matter of such importance that a ministerial decision ought to have been sought. He replied:

<sup>422</sup> See chapter 17, *Blood and Blood Products: Management* for the statutory structure and administrative background.

<sup>423</sup> Day 66, pages 63–64

<sup>424</sup> See, for example, Dr McIntyre's minute of 6 June 1987 to Dr Scott, Mr Morison et al [SGH.002.8127] and the evidence of Mr Macniven – Day 65, pages 174–175

Not necessarily. Obviously, although the Secretary of State ... had at that time statutory responsibility for the health service in Scotland, and a great many other things beside, it would have been impracticable for the Secretary of State personally or indeed a junior minister personally to take a decision on every question that the Scottish Office, as it was then called, was considering. It's a matter of judgment when a topic should be put to ministers, and it looks as if our judgment at the time, certainly the documentary evidence suggests that our judgment at the time was that that did not need to be put to ministers.<sup>425</sup>

**27.293** In addition to matters arising from the general administrative structure, applications for major research funding might require formal review by the CSO Biomedical Research Committee.

**27.294** While the views of SNBTS staff were an important element in the picture, the question as to whether or not surrogate testing should be introduced was not put to Scottish Ministers for decision and, on the evidence as a whole, was never resolved at official level.

**27.295** A decision was not taken by anyone, whether an official of the SHHD or a minister, not to introduce surrogate testing but, instead, SHHD officials took the view that there was not sufficient evidence to recommend to ministers that such testing should be introduced.<sup>426</sup> Dr Macdonald's evidence suggested that there never was a resolution:

I'm not quite sure that a final decision was ever taken. I think we were still agonising over the question of setting up research. Frankly, I just don't quite remember the end of it, except that we didn't do it.<sup>427</sup>

**27.296** SHHD officials, in particular medical officers, considered that there were good reasons for not introducing surrogate testing.<sup>428</sup> The fact that the Department of Health did not support the introduction of surrogate testing was also an important factor in their consideration.

**27.297** Dr Macdonald said:

If departmental medical staff had been persuaded, after consulting colleagues with relevant expertise, that surrogate testing for NANBH was a reliable procedure which would give few false results (positive or negative) and be free from adverse effects, they would have advised administrators accordingly and it would have been highly likely that funding would have been provided. In the event departmental medical staff were not sufficiently persuaded and advice reflected this.<sup>429</sup>

**27.298** Dr Macdonald was not personally involved in the consideration being given in the Department to surrogate testing<sup>430</sup> but he was kept informed of what was happening and did not see any need to intervene.<sup>431</sup> He further explained that if the advice from his colleagues appeared to be veering towards introducing surrogate testing, he would have found it necessary to intervene. He explained his reasons:

<sup>430</sup> The matter being dealt with by Dr Scott, DCMO, Dr McIntyre, PMO and Dr Forrester, SHO

<sup>431</sup> Day 66, pages 63–64

One is that ... it wouldn't be the complete answer to the problem as far as the recipients of blood and blood products were concerned, but it would also have repercussions on the donors. Testing the donors ... would undoubtedly have yielded a fairly appreciable number of positives, some of which would be false and, at the other end, a fair number of negatives, some of which would be false.

If you then – what are you going to do about the positives? You won't know which are false and which are genuine ... there was some risk that we would find that donors would be disturbed by this situation and I think that was something which we really should not have risked doing. That's one side of it.

The other is a point ... about DHSS ... the point that I think has to be made is that DHSS and the Scottish Office, which included SHHD, and for that matter, the Welsh Office, were three different departments of the same government, each responsible to a Secretary of State in that government and the Secretaries of State were sitting together round the same cabinet table.

On an issue of this kind, where there was a group, the Haemophilia Society, and perhaps others, watching all our moves carefully, if one of us – and it might have been us – ... decided to institute testing and the other didn't, that would be extremely difficult to explain. One of us must be right, one must be wrong, would be the reaction.

But it goes a little further than that because, as I recall it, we were facing a situation in which the Scottish [D]irectors were pressing for the introduction of testing and the English [D]irectors – I think pretty unanimously at that stage, the English Directors were against it. I don't think we could ignore the fact that there was a well informed body of opinion, not very far away, with a different view.

So I think in that situation I would certainly need to have become involved.<sup>432</sup>

**27.299** It was suggested to Dr Macdonald that the primary consideration of the SHHD throughout the relevant period was that there should not be any divergence in practice between England and Wales and Scotland. He replied:

I don't think that that – it was an important consideration, certainly, but I think that the staff in SHHD did attempt to form an opinion of their own and that opinion was that we should not go ahead. I think that, if we had agreed with the Scottish [D]irectors' view, Dr Scott would have said so, even if the outcome eventually ... had been different.<sup>433</sup>

**27.300** Dr Macdonald also said that, if he had intervened in the middle of 1987 on the question of surrogate testing, his involvement would have been to say to his medical colleagues that such testing should not be introduced rather than simply to say that there were wider issues which required to be considered.<sup>434</sup>

---

<sup>432</sup> Ibid pages 65–67

<sup>433</sup> Ibid page 157

<sup>434</sup> Ibid pages 67–68

**27.301** Dr Macdonald's succinct explanation as to why surrogate testing was not introduced was that: 'Essentially, there was too much uncertainty about various aspects of surrogate testing to justify introducing it.'<sup>435</sup> He referred to these concerns as relating to 'the quality of the testing'<sup>436</sup> and that 'the screening method was not really good enough'.<sup>437</sup>

**27.302** That explanation is acceptable as an accurate reflection of the factual position at the end of November 1987: the poor sensitivity and specificity of the proposed surrogate tests were likely to give rise to significant difficulties if used for mass screening of blood donors.

### The relationship between the DHSS and the SHHD

**27.303** Dr Macdonald was asked whether it would have been open to Scotland to introduce surrogate testing in the event that the SHHD had taken the view that it was justified but had been unable to persuade colleagues in the DHSS of that justification. He replied:

I think in a very theoretical sense. This was never tested. I think what would have happened, I can, I believe, have advised Scottish ministers that testing should be introduced in Scotland. The CMO and DHSS could have advised his ministers that it should not be tested in England. I think we would have been bound, each of us, to tell our ministers that the other minister was being given the opposite advice. I don't know what would have happened then.<sup>438</sup>

**27.304** He said that it could have become a matter for ministerial decision, possibly at cabinet level.<sup>439</sup> Before pressing matters that far, officials would have had to ask themselves whether they felt so strongly in favour of it that they really wanted their minister to press it.<sup>440</sup>

**27.305** Realistically, the introduction of surrogate testing was not, and was most unlikely ever to have become, an issue requiring a cabinet decision at this time. So far as officials were concerned – and in the first instance the initiative lay with them – it never reached the level of requiring Scottish ministerial decision. Scottish officials were far from convinced that there was an issue worth pressing. However, the possibility of independent action in Scotland led to a discussion of the relationship between the SHHD and the DHSS.

**27.306** There were issues of external perception that would have influenced ministers. Internally, the DHSS would have been expected to take a lead on major policy matters. It was the biggest department and, as Dr Macdonald put it:

SHHD and the Welsh Health Department, would have been expected to fit their policy around that. In other words, there can be a bit of a variation for local circumstances, but broadly the policy would be evolved in DHSS.<sup>441</sup>

<sup>438</sup> Ibid page 82

<sup>439</sup> Ibid page 83

<sup>440</sup> Ibid page 84

<sup>441</sup> Ibid pages 80–81

**27.307** Practical expedients were adopted to avoid problems. Often an expert group would be assembled, sometimes very formally by ministers, and sometimes by the departments. There would usually be Scottish members who would contribute and would be able to give an account of the views of colleagues in Scotland, and an iterative debate would take place. Dr Macdonald thought that on the whole it worked reasonably well. The profession in Scotland was content with it but would have been less content if the DHSS involved only their English colleagues, though the DHSS was sensitive to the issue.<sup>442</sup>

**27.308** Dr Macdonald's view would not necessarily be shared by everyone who had ever participated as a sole Scottish representative on a UK committee dominated by English colleagues. Professor Cash could never have imagined Scotland being allowed by the SHHD 'to go off on our own'. In any event, he considered that there were good reasons relating to seeking to avoid legal liability, team work and the sharing of information for centres, or at least groups of centres, to act in unison in relation to introducing a new test.<sup>443</sup> While acknowledging the positive reasons for collaboration, his assessment of the prospects of Scotland being permitted to take independent action on a matter of this kind is accepted.

**27.309** Dr McClelland took a typically practical view of the position:

I think the decision probably rested with ... the Scottish minister responsible for health, ultimately, as it were, delegated down the line through the department and the [CSA], which was the channel through which our funding arose. But I think that's oversimplistic. I think the minister would inevitably be heavily dependent on the burden of the advice that he or she was given, and if there was very strong, clear, consistent, well-argued and rational advice coming from, say, the clinical and scientific community through the [SHHD] to the minister, I find it hard to believe that most ministers would not have acted according to it. And it's perfectly clear that the advice that was, as it were, coming from the relevant professional community was not clear and consistent.<sup>444</sup>

**27.310** He thought that while there were many obvious advantages in having a coordinated approach throughout the UK. If that meant that something he felt was important to patient safety, such as surrogate testing, was not going to be done, he would have given that a higher priority over 'keeping things tidy and avoiding problems of cross-border differences in practice'. He did, however, consider that surrogate testing could not have been introduced in Scotland without government funding and approval.<sup>445</sup>

**27.311** Dr McClelland's final observation reflected the ultimate reality: where UK government funding was required for major projects, the SHHD had limited scope for major independent initiatives.

**27.312** However, for immediate purposes, it was not a live issue: Scottish administrative officials never promoted for ministerial approval an independent Scottish scheme of surrogate testing. While influenced by the thinking of DHSS colleagues, that was a Scottish decision based on local advice.

## The state of knowledge of NANB Hepatitis in the SHHD

**27.313** There is an issue whether the SHHD had the resources to form views on the threat posed by NANB Hepatitis generally or in particular relation to Scotland. In considering the state of knowledge expected of medical officers in the SHHD at the time Dr Macdonald said:

Generally speaking, we were not individuals who were taking up anything resembling specialist positions. There were one or two examples at variance with that, but broadly speaking we ... would have regarded ourselves as generalists.

....

[I]t is this kind of – relative lack of specialisation, maintaining a degree of generality that is what we wanted.<sup>446</sup>

**27.314** Dr Macdonald was asked what he would have expected his medical officers to do to inform themselves on a particular subject:

In broad terms, I would have expected them to keep up-to-date. I would – how shall I put this? I would perhaps warn him, if I was giving advice, that he has always to remember that the people he is dealing with in the subject know a lot more than he does and he is not going to get himself on to that level.

....

I think they have to go some way towards mastering the subject, but I think what we really expect of them is to be able to come in and tell us what people out there are thinking and be able to explain, to some extent, why they are thinking it, but not to go too deeply into the subject itself .... I think our function was to know enough about medical matters to know what we ought to be asking.<sup>447</sup>

**27.315** He and his colleagues would keep up to date with developments in medicine by reading journals, such as the *British Medical Journal*, *The Lancet* and several public health journals and by attending conferences.<sup>448</sup> As regards NANB Hepatitis, another source of information would be physicians who specialised in the diagnosis and treatment of patients with the disease. They might also have obtained information from the SNBTS Directors, the Scottish Haemophilia Directors and Professor Cash, as National Medical Director of the SNBTS.<sup>449</sup> In addition, SHHD medical officers attended meetings of various advisory committees and working parties as observers and, in that way, would also be able to obtain expert views and advice.<sup>450</sup>

---

<sup>446</sup> Day 66, pages 94–95

<sup>447</sup> Ibid pages 96–98

<sup>448</sup> Ibid page 102

<sup>449</sup> Dr Macdonald – Day 66, pages 130–132. Professor Cash resigned as Consultant Advisor to the SHHD in March 1986 – see his statement in that regard [PEN.017.2767]. Dr Macdonald was not of the view, however, that that changed his relationship with the SHHD in practice: Day 66, page 133. While that also appears to have been the view of Professor Cash in his oral evidence to the Inquiry (Day 72, pages 51–52), in his written evidence he stated that the position he had adopted in 1983 in respect of industrial action at the SNBTS ‘was the cause of an almost complete disruption in professional relations between some important and senior members of the SHHD’s medical team and me’ for a decade and had ‘irreparably damaged’ his professional relationship with Dr Scott, DCMO [PEN.017.2767].

<sup>450</sup> Witness Statement of Dr Scott, DCMO [PEN.017.1854] at 1855 and Witness Statement of Dr McIntyre, PMO [PEN.017.1858] at 1859.

**27.316** In his evidence to the Inquiry Dr Forrester stated that when he joined the SHHD he did not have a great deal of knowledge of problems among haemophilia patients. He explained that he was 'a relayer of information and the gatherer of information from the different sources it could come in'.<sup>451</sup> He did not 'attempt to fulfil the role of a free-standing authority in these matters at all'.<sup>452</sup> Dr McIntyre, Principal Medical Officer, had more experience and expertise in matters relating to the blood transfusion service. Dr Forrester considered that Dr McIntyre 'was always in a position of overlooking what I had done and I put it to him in writing and if there was anything amiss he would have told me'.<sup>453</sup>

**27.317** In various notes and minutes made at the time Dr Forrester commented on the clinical significance of NANB Hepatitis.<sup>454</sup> The general tenor of his comments in documents between 1986 and 1988 was to the effect that the disease was 'relatively benign', at least in the short term. Notwithstanding the risk of serious liver disease, he said that the expression 'relatively benign' was 'a numerical question'. A disease could be 'relatively benign in most cases – in practically all cases'.<sup>455</sup> In a follow-up e-mail to the Inquiry Dr Forrester explained:

Among the meanings of the word "benign" there are two that I believe apply. The first is that in medical and medico-scientific circles, if one form of a fatal disease takes much longer to prove fatal, and does so in fewer cases than another, it is usually termed "benign" in comparison. [Dr Forrester's minutes were directed at such circles.] But in ordinary discourse, and especially if oneself or one's relations are involved, no form of a disease that may prove fatal or disabling can be called "benign".<sup>456</sup>

**27.318** Dr Forrester's view on the prevalence and clinical significance of NANB Hepatitis was influenced by Dr Dow's PhD thesis and by advice received from Dr Reid of the Communicable Diseases Centre. Unfortunately, the Inquiry has been unable to obtain Dr Reid's written replies to Dr Forrester and can only rely on Dr Forrester's record made at the time of his understanding of Dr Reid's views.<sup>457</sup> As regards Dr Dow's thesis, its inadequacy as a means of estimating the true incidence of post-transfusion NANB Hepatitis has already been discussed.

**27.319** Dr Dow's study did not include as one of its purposes an attempt to investigate the clinical significance of NANB Hepatitis. As Dr Dow said to the Inquiry: 'There was no attempt to evaluate the seriousness of the disease, which would have required clinical evaluation by gastroenterologists.'<sup>458</sup> Dr Dow agreed with the suggestion made to him that one would have required to read his thesis along with the wider literature to obtain a more informed view of NANB Hepatitis.<sup>459</sup> He was surprised that a copy of his thesis had been sent to the SHHD but said:

<sup>458</sup> Day 67, page 17

<sup>459</sup> Ibid pages 59 and 65

[I]t was probably the only study done on Scottish patients ... and it probably did give a grass roots level [view] of what was actually happening. It may have given the wrong impression but it was what we actually saw at the time and it was mild in comparison to Hepatitis A and Hepatitis B which really are very severe diseases in their acute form.<sup>460</sup>

**27.320** For his PhD thesis, Dr Dow had the benefit of supervision by Dr Follett, and of his expertise. No criticism is made by the Inquiry of that thesis which was, inevitably, of limited scope and influenced by the state of medical knowledge at the time, for example in relation to the association then made between 'infective jaundice' and NANB Hepatitis. It covered a discrete topic and was never intended to be an exegesis of the whole of contemporary knowledge of NANB Hepatitis.

**27.321** His surprise that the thesis was submitted to the SHHD was both admirable and realistic. Since he himself went on to conduct further research, it can reasonably be inferred that he would have indeed been surprised to learn of the degree of authority accorded within the SHHD to his original work.

**27.322** In his evidence to the Inquiry Dr Macdonald was asked whether there was a greater awareness of NANB Hepatitis among SHHD medical officers than the relatively brief comments contained in Dr Forrester's notes and minutes and said that he thought there was.<sup>461</sup> Dr Macdonald agreed with the suggestion that what was set out in the 7th edition of Patrick Mollison's standard textbook on blood transfusion medicine in the UK in 1983<sup>462</sup> represented the standard or level of knowledge that one would expect of a medical officer in the SHHD who was considering the subject (whether or not that knowledge was derived directly from Mollison's book). He suggested a need for caution when making statements in 1986, for example, about the seriousness of NANB Hepatitis.<sup>463</sup> Dr Macdonald was taken to the statement in the Preliminary Report that '[f]rom about 1985 onwards there appears to have been a growing awareness that [NANB] Hepatitis was a potentially serious and progressive disease which could lead, over time, to cirrhosis of the liver, hepatocellular cancer and death'.<sup>464</sup> He was asked whether that statement was consistent with the statement by Dr Forrester in his note dated 26 January 1987, 'Material for PMO Report', that '[t]his "hepatitis" is a residual rag-bag when Hepatitis B and Hepatitis A are excluded, and consequently no specific test can detect it. It is relatively benign'.<sup>465</sup> Dr Macdonald replied: 'Yes. Well, I think perhaps something should be added to the relatively benign statement to qualify it. Yes, I think a little more could have been said.'<sup>466</sup>

**27.323** In his evidence to the Inquiry Dr McClelland stated:

I think it's entirely reasonable that the relatively small cadre of medical staff in the Scottish Home and Health Department at that time couldn't be expected to be experts in hepatitis.

It does seem ... looking with the wisdom of the retrospectoscope [with the benefit of hindsight] that they were guided very much by one single piece of

<sup>465</sup> Dr Forrester's note [SGH.003.1657]

<sup>466</sup> Day 66, pages 135–136

work, which was the Dow and Follett research, and didn't show – there wasn't much to see in the documentation that they had actually seriously tried to take a more independent look at the literature and the information that was available.<sup>467</sup>

**27.324** When considering Dr Forrester's contemporaneous comments about NANB Hepatitis one must be cautious. First, the records recovered are often relatively brief and may not represent a complete account of Dr Forrester's knowledge at the time. Secondly, Dr Forrester was a generalist public health doctor who would be reliant on the views of experts in particular fields. Thirdly, he was the most junior level of SHHD medical officer (and there is no documentation available to the Inquiry from a more senior medical officer correcting his understanding of the disease). Fourthly, at the material time, Dr Forrester was relatively new in position. Lastly, Dr Forrester's notes must be seen in their wider context – namely, that views in the medical profession about the potential long-term seriousness of NANB Hepatitis did not change overnight, but instead, evolved over time, from about 1985 onwards, as more evidence became available of the risk of progression to cirrhosis. As Dr Forrester put it in relation to his own understanding of the position: 'My impression was this was the way it did seem to able minds at the time. It doesn't mean it was true in the end.'<sup>468</sup>

**27.325** Of course, the available textbooks were slightly out of date: Sherlock had last published her standard textbook in 1981 and Mollison in 1983, and their views were widely relied on in more general textbooks of the period. English colleagues of Dr Forrester used Dr Dow's work as a peg on which to hang their own applications for funding, implicitly suggesting that it contained authoritative data on the position in Scotland.

**27.326** It is clear that Dr Dow came to appreciate that further study was necessary: the Dow, Mitchell and Follett letter to *The Lancet* on 13 June 1987<sup>469</sup> demonstrated that. They drew particular attention to the result of introducing abnormal ALT levels to the diagnosis of post-transfusion NANB Hepatitis in the USA where, when this was done, the rate of infection rose from 0.1–0.2 cases per 1000 units transfused to the significantly higher rate of 10–28 cases per 1000 units transfused. Furthermore, 99% of hepatitis cases were never brought to the attention of transfusion centres. In advocating a prospective study, they demonstrated that they had realised that the conclusions drawn earlier might have been wrong. It is unfortunate that SHHD officials did not adopt this view of the situation but, rather, persisted in according Dr Dow's original work such a high degree of authority.

**27.327** It is regrettable that the preliminary conclusions of Dr Dow's thesis became so firmly established as received wisdom within the SHHD until at least late 1987. Dr Forrester appears by 20 August 1987 to have understood the limitations of the study and clearly sought to influence the terms of the Biomedical Research Committee decision (on the Gillon/McClelland application for funding to join the UK multi-centre study) in his memorandum to Mr Macniven of 1 October 1987 to ensure that the need for new research was not excluded by that decision.<sup>470</sup> It is unclear whether others in the SHHD took the same view. Adherence to the view that the Dow research was a sufficient basis for a decision can only have been because relevant medical officers did not have the

<sup>470</sup> See paragraphs 27.225–27.226 above

knowledge or experience required to assess and understand its limitations in the context of NANB Hepatitis. Given that they were essentially generalists, Medical Officers in the SHHD might have been expected to be less inclined to form and to express views on the highly specialist issues that arose. Instead, they might have been expected to take more formal, structured advice from experts, perhaps engaging a technical committee to advise them in the way indicated by Dr Macdonald and/or by liaising with their counterparts in the DHSS to form a UK committee such as the Advisory Committee on the Virological Safety of Blood, which was eventually set up in April 1989. However, it would be pure conjecture, at this juncture, to attempt to speculate what any advice from such a hypothetical committee would have been.

### ***Clinical significance of post-transfusion NANB Hepatitis***

**27.328** Apart from issues relating to the specificity, sensitivity and general effectiveness of surrogate screening tests as perceived in November 1987, other matters influenced official thinking. The clinical significance of NANB Hepatitis was among these. The evolving state of medical and scientific knowledge in respect of NANB Hepatitis/Hepatitis C is discussed more fully elsewhere in this report.<sup>471</sup> At the beginning of the 1980s NANB Hepatitis was considered to be a generally mild disease with an ‘uncertain but probably benign’ prognosis.<sup>472</sup> From the mid-1980s onwards there was a gradual move away from that assessment towards NANB Hepatitis being viewed as a potentially serious and progressive disease that could, for some patients at least, lead over time to cirrhosis of the liver, hepatocellular cancer and death.<sup>473</sup>

**27.329** There remained a persistent view throughout the 1980s in some quarters, however, that despite an increasing body of evidence to the contrary, NANB Hepatitis was only rarely transmitted by blood and was usually not particularly serious.<sup>474</sup>

**27.330** For administrators, however, the question was not whether one or other view of the risk of transmission or of the seriousness of the disease was correct in absolute terms. Rather, the issue was whether there was a sufficient body of reliable opinion that NANB Hepatitis did present a serious risk, to bring that into account in determining whether research was required and should be funded and what the scope of that research should be. It is clear that SHHD officials, including medical staff, were not competent to make that judgment themselves. They were confronted by conflicting views from people they were entitled to look to for expert advice. That was an additional factor pointing to the need for structured study of the problem, with the benefit of an expert committee to advise them. It is a matter of regret that by late 1987 sufficient information had not been gathered to reach an informed view.

**27.331** Apart from the fundamental question of the natural history of NANB Hepatitis, however, two further factors came to prominence in 1988: the impact of surrogate testing on the blood supply and the problems associated with counselling of donors.

***Impact on the blood supply***

**27.332** Several studies were carried out into the likely loss of donations in the event surrogate testing was introduced.

**27.333** Dr Gillon's study of Edinburgh blood donors found that 2.4% of a cohort of regular donors had elevated ALT levels<sup>475</sup> and 2% was positive for anti-HBc. There was no overlap between these two donor groups with the result that, based on these findings, combined screening would have led to an initial loss of 4.4% of donations (from this cohort).<sup>476</sup> It was concluded that:

In view of the medical and economic implications of the introduction of these screening tests, and the poverty of data on the clinical significance of post-transfusion [NANB] hepatitis ... such a screening programme cannot be justified at present. Further studies are required, including a prospective controlled trial of the effects of screening.<sup>477</sup>

**27.334** The evaluation of ALT testing equipment by the SNBTS Microbiological Validation Group found that a cut-off of 2.5 standard deviations above the mean would lead to the exclusion of approximately 1.5% of donations and that a cut-off of 2 standard deviations above the mean would lead to the exclusion of approximately 5% of donations.<sup>478</sup>

**27.335** The multi-centre study in England found that 3.2% of donors would have been rejected using ALT screening, that 0.63% of donors would have been rejected using anti-HBc screening and that there was little overlap between these groups of donors.<sup>479</sup>

**27.336** Looked at overall, had both ALT and anti-HBc screening been introduced in Scotland it seems likely that between 3% and 5% of donations would have been excluded on initial screening.<sup>480</sup> In the case of regular donors, the loss would remain as long as they continued to have elevated test results.

**27.337** As noted by Dr McClelland:

These numbers may have underestimated the longer term effect on donor attendances, because later research has shown – perhaps not surprisingly – that donors who are rejected on one occasion are unlikely to return to volunteer again, and this tends to have a cumulative effect that is not measured by the initial rate of deferral.<sup>481</sup>

**27.338** At the time of the SNBTS Directors' recommendation on 3 March 1987<sup>482</sup> that surrogate testing should be introduced with effect from 1 April 1988, there was no recorded discussion of the effect on the blood supply of introducing such testing.

**27.339** By 1988, a fall in donor attendances had become a matter of concern. In the introduction to the SNBTS 1988 PES bid (prepared around June 1988), Professor Cash stated:

<sup>475</sup> ie above 45 units per litre

<sup>476</sup> Gillon et al, 'Post-transfusion [NANB] hepatitis: significance of raised ALT and anti-HBc in blood donors', *Vox Sanguinis*, 1988; 54:148 [SNB.008.3536]

<sup>477</sup> Ibid [SNB.008.3536] at 3536

<sup>480</sup> In their evidence to the Inquiry, Dr McClelland thought 3-4% [PEN.017.2651] at 2654 and Professor Cash thought between 1-3% [PEN.017.1885] at 1889

<sup>481</sup> Supplementary statement [PEN.017.2651] at 2654

<sup>482</sup> Minutes of the SNBTS Directors' meeting, 3 March 1987 [SGH.001.6653] at 6658

1987/88 has been the year when, perhaps, for the first time since its foundation in the early 1940s, serious doubts have arisen with regard to the ability of the SNBTS to sustain the quantity and volume of its service to the [Scottish Health Service] and meet the needs of the future.<sup>483</sup>

**27.340** The problems included a decline in total donor attendances, an escalation in demand for blood products and resulting problems in supply and self sufficiency.

**27.341** As regards the decline in donor attendances, Professor Cash noted that there had been a 'sustained decline' in attendances since 1985 which had 'become more evident in the last 18 months'.<sup>484</sup> The total annual donor attendances showed that, from a high of 338,278 in the year ended 31 March 1985, there was a decline to 333,112 attendances in 1986, 331,089 in 1987 and 315,845 in 1988.<sup>485</sup> Investment totalling £221,000 was sought in the 1988 PES to appoint a national donor recruitment and blood collection manager, to fund a permanent media publicity programme and to improve the conduct of blood donor sessions.<sup>486</sup>

**27.342** As regards the escalation in demand for blood products, Professor Cash explained in the 1988 PES that '[t]here has been a significant and substantial increase in the clinical demand/use of SNBTS blood and blood products over the last decade' which was 'out of control'.<sup>487</sup>

**27.343** As far as supply and self-sufficiency were concerned, the 1988 PES noted that 'major difficulties' had emerged for RTCs in meeting demand centred primarily on the provision of platelet concentrates and supporting the fresh plasma needs of the PFC.<sup>488</sup> It was noted that 'further significant increases in fresh plasma for PFC cannot be obtained from the existing blood donation input (which is falling in any event)' and that the major contribution to any planned increases in plasma were likely to be by a mixture of plasmapheresis and optimal additive solution (OAS).<sup>489</sup> Investment of £650,000 was sought in the PES to address these concerns.<sup>490</sup>

**27.344** In a letter to Mr Donald of 25 July 1988, Professor Cash ranked the various bids in the 1988 PES in order of priority.<sup>491</sup> The sums sought to address escalating demand, supply and self-sufficiency and falling donor attendances were included in the highest priority category. In contrast, the sums sought for ALT testing were in the medium priority category.

<sup>483</sup> SNBTS PES Programme Narrative, 1988 [SNB.003.3078] at 3088

<sup>484</sup> Ibid [SNB.003.3078] at 3089

<sup>485</sup> Ibid [SNB.003.3078]. The total number of donations collected in these years, although not shown in the 1988 PES, fluctuated from 304,914 in 1985, 309,748 in 1986, 289,006 in 1987 and 310,785 in 1988. SNBTS paper on Blood Collection 1975-1991 [PEN.010.0026] at 0029. Compare Chapter 3, *Statistics*, Table 14

<sup>486</sup> SNBTS PES Programme Narrative, 1988 [SNB.003.3078] at 3090

<sup>487</sup> Ibid [SNB.003.3078] at 3090 and 3091. The 1988 PES contained figures showing that the demand for albumin had trebled between 1978 and 1988, and between 1985 and 1988, had increased by a quarter; the demand for Factor VIII had risen almost six-fold between 1978 and 1988, and between 1985 and 1988 had risen by over a quarter; the demand for Factor IX in 1988 was almost 16 times that in 1978 and had doubled between 1985 and 1988, [SNB.003.3078] at 3091. The PES narrative stated that while the increase in demand for blood products was not unique in Scotland, there was circumstantial evidence of over-prescribing of products and a sum of £73,300 was sought for the establishment of an academic department of Transfusion Medicine whose primary purpose would be to develop research directed towards defining the appropriate treatment of disease using blood and blood products: [SNB.003.3078] at 3092 and 3093.

<sup>488</sup> SNBTS PES Programme Narrative, 1988 [SNB.003.3078] at 3093

<sup>489</sup> Ibid [SNB.003.3078] at 3095. When plasma is removed from a donation of collected whole blood it is replaced with OAS which optimises red cell preservation and lowers viscosity. The use of OAS allows more plasma to be taken from the donation.

<sup>490</sup> The £650,000 sought comprised £250,000 in respect of a new staffing structure at the PFC and £400,000 in respect of RTC 'plasma procurement' – that is, the implementation of plasmapheresis and OAS [SNB.003.3078] at 3098

<sup>491</sup> Letter [SNB.011.4790]

**27.345** In his evidence to the Inquiry, Dr Mitchell was asked whether a loss of 4% or 5% of donors in the west of Scotland would have created a problem for the blood supply and he replied that it would.<sup>492</sup> He was then asked whether that would have been an insurmountable problem and replied:

With sufficient drive perhaps it could have been overcome ....

And so the answer to that is, yes, we could probably have overcome the problem. It would have taken a lot of additional advertising, and it's difficult to see how you would recruit donors faced with the knowledge that you were imparting through their colleagues at the workplace, who were not infected, but had a marker which was putting them off-service. They would be saying to themselves "Well, I'm not going. If you are not going to go, I'm not going because I might be turned down the same as you". And once you are turned down, then you have a problem. I have said to you many, many times, a donor becomes a patient ....<sup>493</sup>

**27.346** Dr Gillon stated:

The situation became serious to the extent that a substantial injection of resources was necessary around 1990, with most of the money and effort going into a television advertising campaign which reversed the decline in donor numbers. Whether it would have been possible to weather a loss of donations of the order of at least 4-5% and so maintain self-sufficiency with or without such funding is doubtful, but this is speculative in the extreme.<sup>494</sup>

**27.347** Professor Cash was asked whether, given the difficulties in blood collection in the second part of the 1980s, it would have been feasible to introduce surrogate testing at any time between 1987 and 1990. He replied that, had he been asked about surrogate testing at the end of 1987, his position would probably have been: 'Go away ... forget it in the meantime.' He stated that in 1988/89, 'we would have been struggling a little.' Progress was, however, being made in that unnecessary use was being reduced, stocks were being moved around and the problems in the west of Scotland were eventually resolved.<sup>495</sup>

**27.348** Although these problems were dealt with, it appears that the Scottish service was not well placed at this time to withstand any further reductions in donations, in particular if self-sufficiency in blood products was to be maintained. The potential sensitivity of donors to the implications for them of surrogate testing added to the difficulty.

### *Counselling of donors*

**27.349** As noted above, surrogate tests such as ALT and anti-HBc markers were non-specific indicators of the presence of NANB Hepatitis.

**27.350** In his written evidence to the Inquiry Dr McClelland stated:

Low test specificity ... has serious consequences when a test is used to screen a member of a healthy population. A substantial proportion of the individuals

<sup>492</sup> Day 65, pages 47-48

<sup>493</sup> Ibid page 48

<sup>494</sup> Statement [PEN.017.1931] at 1938

<sup>495</sup> Day 72, pages 38-42. He also gave evidence on his concerns that the donor panel may have 'collapsed' as a result of excluding a large number of donors on the basis of a non-specific surrogate test for which there was no confirmatory test: Day 72, pages 63-64

who test “positive” and who therefore will be rejected as donors because of the risk of transmitting [NANB Hepatitis], will not in fact, have [NANB Hepatitis] nor will their blood contain the relevant infectious agent. Nevertheless, such individuals have to be informed that their donations can no longer be accepted and the risk that their blood could transmit hepatitis must be part of the explanation. This can have the effect of converting a person who correctly considers themselves to be in good health into one who has been given information that indicates that they may be afflicted with a serious infection. This problem can only be avoided if there is some form of additional test (often termed a confirmatory test) that can reliably demonstrate the presence or absence of infection.<sup>496</sup>

**27.351** Until the Hepatitis C virus was identified in 1988, and a test for antibody to Hepatitis C became available the following year, there was no direct test – far less a confirmatory test – for the agent or agents responsible for NANB Hepatitis.

**27.352** Taking Dr McClelland’s oral evidence as a whole, it is clear that there was concern as to how the SNBTS would have managed donors who were rejected on the basis of a surrogate test. It was suspected that in most cases a positive test would not indicate infection.<sup>497</sup> Effective counselling of donors who tested positive for surrogate markers would have been a ‘challenging problem’ for the service. Further thought required to be given to the practical arrangements for counselling the many thousands of donors who would test positive for surrogate markers and the SNBTS had little practical experience of such counselling to draw on.<sup>498</sup> The numbers involved in Hepatitis B and HIV testing had not been large and, furthermore, in relation to these infections confirmatory tests were available.

**27.353** On reflection, Dr McClelland accepted that the SNBTS Directors ‘certainly had not ... prepared a systematic sort of management plan and costed out the stuff involved’. He remained ‘absolutely confident’, however, that, looking at the implications for the other hospital departments and GPs, the issue of donor counselling ‘could and would have been addressed’.<sup>499</sup>

**27.354** Dr Mitchell was altogether less confident. He emphasised the uncertainties that arose from the fact that ALT levels could fluctuate and that elevated ALT had many different causes, many or most of which had nothing to do with hepatitis.<sup>500</sup> In his view, a donor who tested positive for a surrogate marker would become a patient.<sup>501</sup> Asked whether that would not have been a reason to avoid testing, Dr Mitchell commented:

No, provided the basis on which you make him a patient is justifiable ....

What do you say, “Go and see your GP”? The GP immediately phones us and says, “What does this mean?”, “I don’t know what it means, but I know what you are getting at”, but he says to me, “But this chap is sitting in front of me and he is dead scared, he’s worried, “What’s going to happen to me?” I can’t tell him anything”. I say, “Neither can I”.<sup>502</sup>

<sup>500</sup> Day 65, pages 15–16

<sup>501</sup> Ibid page 48

<sup>502</sup> Ibid pages 64–65

**27.355** On Dr Mitchell's approach, there were many questions for which practitioners had to have answers before proceeding to implement surrogate testing.

**27.356** Dr Gillon's experience with donors supported the view that there was a problem with counselling. Donors in his study into surrogate markers who were found to have elevated ALT levels 'were quite anxious, they were very keen to know the next set of results, and they were really quite concerned about this'.<sup>503</sup> Dr Gillon also had experience of counselling plasmapheresis donors with elevated ALT and stated:

As soon as you see somebody, sit them down and say, "There may be something wrong with your liver, you may be carrying some nasty virus that may or may not cause chronic liver disease. We may have to send you to a specialist. They may stick a needle in your liver". It was not trivial. It is absolutely not trivial.<sup>504</sup>

**27.357** Dr Macdonald said:

It's not simply a matter of counselling and advice but there would be a number of donors identified who would have to be referred to a physician, subjected to laboratory tests, reviewed for a period of at least some months, I would have thought, before it would be possible to offer them an opinion as to whether they were infected or not. In other words, whether they were the false positives or genuine positives. Yes, there is quite a lot involved in this.<sup>505</sup>

**27.358** Notwithstanding Dr McClelland's confidence that a solution would have been found, and quite irrespective of the numbers involved, the introduction of surrogate testing would have required resolution of the many issues relating to informing donors, providing counselling and regulating follow-up, all of which were inherent in using a mass screening test of such poor specificity and sensitivity.

**27.359** The scale of the problem – the number of donors who might have required counselling and investigation – added to the underlying difficulty. In the mid- to late-1980s approximately 300,000 blood donations were collected annually in Scotland.<sup>506</sup> The number of donors is likely to have been considerably lower. As noted in Chapter 18, *Collection of Blood in Scotland: General*, paragraph 18.14, at the date of the Inquiry's hearings 80% of donors bled were not 'new' and return donors contributed about 85% of all donations. These percentages must fluctuate and a 'new' donor in January may become a return donor in May and September. On the evidence, a return donor might give 1.06 donations a year on average. It is not possible to extrapolate on any reliable basis from the findings of a limited study to an estimate of the potential loss to the blood supply. However, for illustrative purposes only, total donors for 300,000 donations might be the sum of new donors ( $300,000 \times 15\% = 45,000$  individuals) and return donors ( $255,000/1.06 = 240,566$ ), a total of 285,566 individuals. If ALT testing had been introduced then, on the best current estimates, approximately 3% of donors might have been expected to have had elevated levels, just over 8500 donors per year. Dr Gillon's study had found that about 80% of donors with elevated ALT had a 'non-viral' explanation, such as obesity or alcohol.<sup>507</sup> Based on Dr Gillon's findings, about 6800 might

<sup>507</sup> Gillon et al, 'Post-transfusion [NANB] Hepatitis: significance of raised ALT and anti-HBc in blood donors', *Vox Sanguinis*, 1988; 54:148 [SNB.008.3536]

be expected to have had a 'non-viral' explanation for their condition, leaving 1700 – 0.6% of the total number presenting with a view to donation – who would have elevated ALT for which a viral explanation was possible. In a Finnish study by Freja Ebeling and colleagues, the authors considered that the positive predictive value (the number of true positive results amongst the 'positive calls') of an elevated ALT level in identifying those donors who transmitted NANB Hepatitis was about 4%.<sup>508</sup> While for a number of reasons one must be very cautious about relying on that figure, for purely illustrative purposes it would suggest that if about 1700 donors a year in Scotland were found to have elevated ALT levels deemed to be associated with NANB Hepatitis, about 68 donors would be infective and the remaining 1632 would be 'false positives'.

**27.360** The concerns about the impact on donors, often advanced by practical transfusion doctors, were significant. Giving a label of uncertainty to individuals who were likely in the nature of things to be immediately anxious would have been a serious matter. Had it been intended to introduce surrogate testing of donated blood generally, it would have been necessary to have developed clear guidance on how donors found to have elevated ALT or to be positive for anti-HBc were to be dealt with and, in particular, counselled. The risk of false positive results would have presented a particular challenge. That stage was not, in the event, reached. The evidence of Dr Mitchell, Dr McClelland and Dr Gillon made it clear that finding a satisfactory solution that would have had general support would not have been easy.

#### *The perceived benefits of surrogate testing*

**27.361** The preceding discussion has considered the various difficulties with using surrogate tests to screen donors for possible NANB Hepatitis infection. One must also, however, consider the evidence that was available at the time in respect of the advantages of surrogate testing including, in particular, the extent to which surrogate screening may have reduced the incidence of transfusion-transmitted NANB Hepatitis infection. A full cost/benefit analysis does not appear to have been carried out, and, indeed, such an analysis could not have been carried out in any meaningful way in the absence of a large-scale prospective study of the prevalence of NANB Hepatitis in Scotland and of the efficacy of surrogate testing here. As discussed above, such a study would have been required to extend beyond the investigation of the prevalence of surrogate markers in donors and to have included investigation of the link, if any, between such surrogate markers and the development of post-transfusion NANB Hepatitis in recipients. A study of that scope was never properly considered or carried out in the UK. The perceived benefits of surrogate testing in the late 1980s can therefore be considered only on a more general basis.

**27.362** Dealing, first, with patients with blood disorders, the size of pools (containing many thousands of donations) used to manufacture Factor VIII and Factor IX meant that most were likely to have contained at least one donation containing HCV (which donation would potentially have infected the whole pool). Given the poor sensitivity of surrogate testing as a screening test, it was never likely to have been effective in identifying and excluding all infective donations. The safety of factor concentrates, therefore, depended not on surrogate screening of donations but on the development and introduction of manufacturing processes that inactivated any virus in the pool. By the end of 1987 the PFC had already issued products sufficiently heated to inactivate HCV-infecting source

---

<sup>508</sup> Ebeling et al, '[ALT], gamma-glutamyltransferase, [anti-HBc] and [anti-HCV] in blood donor screening', *Vox Sanginis*, 1991; 60:219 [PEN.017.1763] at 1765, Table 4

plasma. In particular, heat-treated Factor IX concentrate (DEFIX) was issued in August 1985 for routine clinical use in the treatment of Haemophilia B.<sup>509</sup> The PFC's heat-treated FVIII concentrate, Z8, was issued for routine clinical use in the treatment of Haemophilia A in April and May 1987.<sup>510</sup> Patients receiving factor concentrate therapy with NHS products after those dates would not have been infected due to the inactivation procedures. Surrogate testing of blood donations would not have added to the security of recipients of these products in haemophilia therapy.

**27.363** Further, most patients who had routinely received blood products before the introduction of the heat-treated concentrates had almost certainly already been infected with NANB Hepatitis/HCV. That was the conclusion of a number of studies: most haemophilia patients, whether treated with NHS concentrates or concentrates produced by commercial companies, were likely to have developed NANB Hepatitis on first exposure to concentrates that had not been virally inactivated.<sup>511</sup> Only haemophilia patients receiving single or small numbers of doses of cryoprecipitate (made from pools of around 10 donations), who were in broadly the same position as medical and surgical patients receiving transfusions of blood or blood components, might have benefited. The topic of relevance is primarily in those cases.

**27.364** As regards transfusion of whole blood and its components,<sup>512</sup> the TTV and NIH studies suggested in 1981 that in the USA (and therefore in the context of the specific characteristics of that country's blood donor population), ALT testing might have reduced the incidence of post-transfusion NANB Hepatitis by 30–40%.<sup>513</sup> The same studies, reporting in 1984 and 1986, suggested that anti-HBc testing might reduce the incidence of post-transfusion NANB Hepatitis by about one third.<sup>514</sup> The ALT and anti-HBc tests largely identified different groups in the donor population. However, even if these predictions had been correct, on average two-thirds of the pre-screening risk of transmission would have continued despite screening.

**27.365** Importantly, the TTV and NIH estimates of the extent to which surrogate testing might have reduced the incidence of post-transfusion NANB Hepatitis were predicted efficacies (based on an historical analysis of existing data) rather than actual efficacies (based on a randomised prospective study whereby one group of patients was given blood which had been screened for surrogate markers and the other was given blood that had not been so screened). Very few randomised prospective trials were carried out and published before the late 1980s to establish the actual efficacy of surrogate testing in reducing the incidence of post-transfusion NANB Hepatitis. Those that were published in the early- to mid-1990s were too small for reliable conclusions to be drawn from their results.

**27.366** The letter from Dr Gillon and his colleagues published in *The Lancet* on 13 June 1987 commented on the published literature as at mid-1987:

Of the four small prospective studies, two using ALT screening and two using anti-HBc, three<sup>515</sup> failed to demonstrate any reduction in post-transfusion NANB hepatitis as a result of donor screening and one<sup>516</sup> found an apparent association between anti-HBc in donor units and recipient hepatitis.<sup>517</sup>

**27.367** The information available at the time on the likely benefits of surrogate testing therefore remained inconclusive. The majority of small-scale prospective studies had failed to demonstrate the reduction in post-transfusion NANB Hepatitis that was predicted by the TTV and NIH studies when blood with surrogate markers was withheld.

**27.368** There was an additional difficulty in relying on these data. Prevalence in the US donor population could not be assumed to be representative of the prevalence of NANB Hepatitis elsewhere. Prevalence in the USA was generally believed to be relatively high and, as Professor Leikola said, most countries that elected to introduce surrogate testing in 1987 first conducted research to find out the situation in their own donor population and did not simply follow the US example.

**27.369** There are other difficulties in trying to estimate the extent to which surrogate testing might have reduced the incidence of post-transfusion Hepatitis C in Scotland. Dr Gillon, for example, took the view that predictions of a reduction of cases of post-transfusion NANB Hepatitis by 30% or 40% following ALT testing would almost certainly have been too high for a number of reasons, including that donors rejected on surrogate screening would have to be replaced with new donors. The introduction of anti-HCV screening had shown that new donors had an increased prevalence of HCV when compared with existing donors. That factor, unknown and unknowable in extent, would require to be taken into account when calculating the efficacy of surrogate testing. Dr Gillon explained: 'I know Harvey Alter talked about a corrected efficacy to try to accommodate that, and that dropped his predicted efficacy from 40% to 20%, but it was totally speculative.'<sup>518</sup>

**27.370** Developing knowledge of other causes of elevated ALT became significant. Hepatitis C causes liver damage and elevated ALT is an indicator of liver damage (from whatever cause). It was reasonable to infer that donors with Hepatitis C were more likely to have elevated ALT than donors who were not infected. Elevated ALT is, however, also associated with other factors, such as obesity and alcohol intake, and these required to be excluded before an inference of Hepatitis C infection could be drawn from the finding. In addition, as Dr Gillon explained:

The segment of the population with the highest mean [ALT] levels is in males aged 30 to 40 ....

<sup>515</sup> Alter, H 'Post-transfusion hepatitis: clinical features, risk and donor testing', in *Infection, Immunity and Blood Transfusion*, 1985, Alan R. Liss, pages 47–61, at 55 [LIT.001.0811], Steinbrecher et al, 'Abnormal alanine aminotransferase level in blood units from donors in Montreal does not indicate high risk of transmitting hepatitis', *Clinical and Investigative Medicine*, 1983; 6:327 [LIT.001.2207] and Aynard et al, 'Post-transfusion [NANB] Hepatitis after cardiac surgery: prospective analysis of donor blood anti-HBc antibody as a predictive indicator of the occurrence of [NANB] hepatitis in recipients', *Vox Sanguinis*, 1986; 51:236 [LIT.001.3810]

<sup>516</sup> Sugg et al, 'Antibodies to hepatitis B core antigen in blood donors screened for alanine aminotransferase level and hepatitis [NANB] in recipients', *Transfusion*, 1988; 28:386 [LIT.001.3813]

<sup>517</sup> Gillon et al, '[NANB] hepatitis surrogate testing of blood donations', *The Lancet*, 13 June 1987:1366 [LIT.001.0346]

<sup>518</sup> Day 65, page 77

In most studies of HCV-positive blood donors, there is found to be a preponderance of males, typically in the age range 30-40. There is therefore a coincidental association between higher ALT levels and the donors most likely to have been exposed to HCV. It is therefore likely that ALT is to some extent an epiphenomenon in statistical or epidemiological terms [that is, a secondary phenomenon without a necessary causal relationship to the primary disorder] as Alter and Holland suggested.<sup>519</sup>

**27.371** The information available from later investigations suggests that, viewed exclusively in terms of efficacy, surrogate testing for elevated ALT would probably have reduced the incidence of transfusion-transmitted hepatitis for some recipients of blood, blood components and single donor preparations such as cryoprecipitate, if introduced between 1988 and 1991. The extent to which that would have happened cannot be quantified, given the difficulties with the evidential material previously discussed.

### *Product liability*

**27.372** Council Directive 85/374/EEC, imposing strict liability for harm caused by defective products came into force in the UK on 1 March 1988 under the Consumer Protection Act 1987.<sup>520</sup> In *A v The National Blood Authority and Others*, Mr Justice Burton decided on 26 March 2001 – for the time being conclusively – that as of 1 March 1988 recipients of blood or blood products which transmitted HCV infection, had suffered harm for which a remedy was available under the terms of the Directive. The circumstances of the case are discussed in Chapter 31, *The Introduction of Screening of Donated Blood for Hepatitis C*, at paragraphs 31.432–31.437.

**27.373** SNBTS officials, particularly Professor Cash but including the Transfusion Directors generally, anticipated that there would be strict liability under the Directive and engaged that risk by contending that surrogate testing should be introduced. The ‘irrational but perhaps inescapable’ conclusion was perhaps most clearly expressed in the letter to *The Lancet* dated 4 July 1987 and discussed at paragraphs 27.206–27.207.

**27.374** As originally argued by Professor Cash, the risk of strict liability, for the SNBTS in particular, was presented as a reason for the UK to attempt to exclude blood and blood products from the scope of the legislation. That argument failed to achieve support from the DTI and it was accepted by the SHHD that blood and blood products would remain within the scope of the act. Once that position was accepted, the success of the UK public sector producers of blood products and of the transfusion services in escaping liability, inevitably depended on the view taken by the court of the effect of the legislation and, in some respects more critically, of the facts found by the court on the evidence before it.

**27.375** The facts found in *A v The National Blood Authority and Others* are not determinative of the factual issues that arise on the evidence before the Inquiry which remain facts for the Inquiry to determine. In particular why surrogate testing was not introduced and whether it should have been introduced are issues the Inquiry must deal with on the evidence now available.

---

<sup>519</sup> Ibid page 98. The reference to Alter and Holland is a reference to their December 1984 editorial discussed above at paragraphs 27.40–27.41 [PEN.018.1156]

<sup>520</sup> See paragraphs 27.150–27.154

***Why surrogate testing was not introduced and whether it should have been introduced***

**27.376** Central to this discussion are questions as to whether the UK Government departments, particularly the DHSS and the SHHD, were wrong to have first delayed and then failed to institute general surrogate testing of blood donations for high ALT levels and anti-HBc. Since HCV screening was introduced generally on 1 September 1991, the relevant period for considering these questions can be taken to have ended on that date: there was no general safety issue to be addressed by surrogate screening thereafter, whatever commercial reasons fractionators might have had for continuing with the practice. The issue had, however, already changed in the course of the period ending on that date. It is relevant and material to note that as the period proceeded it became clear (and was certainly clear by the date of the introduction of HCV screening) both that the large majority of cases of post-transfusion NANB Hepatitis/HCV were attributable to a single virus and that screening and confirmatory tests for HCV were increasingly of reasonable sensitivity and specificity. As the tests improved, particularly in relation to those genotypes of HCV prevalent in the UK, the potential relevance of surrogate testing diminished.

**27.377** There is, however, a short and compelling answer, at least from March 1989 onwards, when the ACVSB was set up: given the advice of the committee, the appropriate expert advisory group established to provide objective and independent advice to government, that the blood transfusion services should not introduce surrogate testing, there was no medical or scientific basis on which the DHSS and the SHHD could properly have done otherwise.

**27.378** The issue is not whether, having regard to subsequent developments in medical and scientific knowledge, the expert advice tendered was correct or incorrect. The members of the ACVSB included eminent experts of national and international repute who were leaders in their fields. Professor Zuckerman, for example, appears from the record to have been a significant voice influencing the direction of thought throughout this important period. It would be inappropriate with the benefit of hindsight to analyse his advice and, in comparison with others' views, comment on the validity of his opinions. The Inquiry is not tasked with an assessment of professional opinions responsibly held and expressed as guidance to government. At the time, the NHS, the Scottish agencies, the SHHD and the government generally were entitled to rely on the advice given by appropriate experts and to act accordingly. Ministers would have required clear and powerful scientific advice to the contrary before taking a different course. At no point was there clear and powerful advice in favour of the introduction of surrogate testing in Scotland or the rest of the UK.

**27.379** Before the ACVSB was set up, however, the question was more open. Until the decision of the AABB (in the USA) in August 1986, there was no consensus anywhere that surrogate testing was appropriate as a method of screening blood for NANB Hepatitis. In the UK, there was never a medical and scientific evidential basis to justify the introduction of a mass screening test of such poor sensitivity and specificity. The lack of sound medical and scientific reasons for the introduction of surrogate testing was recognised by the SNBTS Directors who instead, in their letter to *The Lancet* of July 1987, pointed to other factors which they considered meant that surrogate testing was 'irrational, perhaps, but inescapable'. These other factors included forthcoming product liability legislation already referred to and pressures arising from the practice of commercial manufacturers.

**27.380** It was suggested in closing submissions to the Inquiry that the SNBTS Directors failed to explain properly to the SHHD their reasons for recommending the introduction of surrogate testing, including the benefits to patient safety and that, for their part, the SHHD failed in not asking the SNBTS Directors to clarify the reasons for their recommendation.<sup>521</sup> The Directors' reasons for making their recommendation were stated at the time to be based on the fact that blood banks and fractionators elsewhere, in particular in the USA, were introducing ALT testing and because of new product liability legislation. The SHHD officials were aware of the SNBTS Directors' concerns in that regard, even if they did not agree with them.

**27.381** Given the lukewarm support of the SNBTS Directors for surrogate testing and the lack of data in the UK as to its efficacy in preventing or reducing transfusion-transmitted NANB Hepatitis, it would be unrealistic to proceed on the basis that the Directors should have been expected to provide much more by way of clarification of their reasons for 'recommending' the introduction of surrogate testing. It was not a fully reasoned response to the problem, which remained that surrogate testing was a controversial topic which did not command widespread scientific support outwith the USA. The Directors' reasons for their recommendation, so far as they were developed and expressed, were known to the SHHD. They were not persuasive without the backing of relevant research.

**27.382** There was, at least potentially, an independent question for the SHHD: whether, having regard in particular to the impending product liability legislation, a full cost/benefit analysis would have tended to support surrogate testing, notwithstanding its limitations. That was, however, never carried out. It would have been a complex exercise, not least because of the incalculable impact on donors and the blood collection complex of inefficient screening technology. It would not be appropriate to speculate on what the outcome of such an analysis might have been.

**27.383** In his written evidence Professor Leikola commented on the fact that surrogate testing for NANB Hepatitis was not introduced in the UK. Even on the basis of all that is now known, it was reasonable and correct, in his view, for the UK not to have introduced surrogate testing.<sup>522</sup> So far as anti-HBc testing was concerned, its use as a surrogate marker could not be validated. He considered that ALT testing might have been more logical but observed that it was used in some countries, not because of a scientific basis and logical reasoning but because of public pressure.<sup>523</sup>

**27.384** As noted above, Dr Macdonald explained that surrogate testing was not introduced because, '[e]ssentially, there was too much uncertainty about various aspects of surrogate testing to justify introducing it.'<sup>524</sup> He referred to these concerns as relating to 'the quality of the testing'<sup>525</sup> and that 'the screening method was not really good enough'.<sup>526</sup>

**27.385** Dr Macdonald was also asked whether, with the benefit of current knowledge of Hepatitis C, he would be any more positive towards surrogate testing; he replied that he did not think he would be, given the non-specific nature of surrogate testing, the number

<sup>522</sup> Professor Leikola's statement on surrogate testing [PEN.017.1837] at 1841

<sup>523</sup> Prior to the research carried out by Dr Ebeling and others surrogate testing for ALT or anti-HBc had not been routine practice in Finland: Ebeling et al, 'Post transfusion hepatitis after open-heart surgery in Finland – a prospective study', *Transfusion Medicine*, 1991; 103: 108. [PEN.017.1777] at 1780

<sup>524</sup> Dr MacDonald's Witness Statement [PEN.017.1702] at 1709

<sup>525</sup> Day 66, page 87

<sup>526</sup> Ibid pages 116–7

of false positives that would arise and the fact that such testing would not be able to completely eliminate infection.<sup>527</sup> He was also asked whether, hypothetically speaking, if it was reasonably believed that the introduction of surrogate testing was likely to reduce the incidence of post-transfusion hepatitis by, say, 30–40%, he considered there then arose a reasonable case for introducing surrogate testing. He replied:

No, I think I would still have argued against it. I think too much uncertainty still remained and I would have put considerable weight on the possibility that donors would find it disturbing. I think the one thing that we really had to avoid, almost at any cost, was disturbing donors because the whole enterprise depended on them.<sup>528</sup>

**27.386** While in his evidence to the Inquiry, Dr McClelland stated that patient safety was ‘the’ reason why he favoured the introduction of surrogate testing,<sup>529</sup> that can only have been in a very general and inchoate way, given the fundamental problem that one could not make a fully reasoned and scientific case for its introduction, including quantifying any benefit in recipient safety, because of the lack of adequate evidence and research in the UK into the prevalence of post-transfusion NANB Hepatitis and the likely efficacy of surrogate screening in reducing the transmission of the disease through transfusion. Furthermore, the issues identified by Dr Mitchell and Dr Gillon around the risk of turning thousands of healthy donors, found to have elevated ALT levels on surrogate testing, into patients concerned about the implications of test results for their long-term health that could not be resolved, were real obstacles to the introduction of the tests on a routine basis. The impact on the blood supply was also a legitimate concern, in particular against the background of a fall in donor attendances around this time, an increase in demand for blood products and the resulting difficulty in maintaining a policy of self-sufficiency in blood products.

**27.387** From May 1987, the general European position was that each country should ascertain the prevalence of NANB Hepatitis infection in its own region and take a decision on that basis. In Finland, a decision to carry out a study was implemented, the study beginning in December 1987 and lasting a year. Had Scotland followed the Finnish pattern, the results of such a study would not have been available before the ACVSB was established. The timescale anticipated by the SNBTS in their letter to *The Lancet* in July 1987 was three to four years. However, Dr McClelland had been pressing for such a study since 1981. As narrated, his early efforts failed in consequence of decisions taken by the MRC and the transfusion services’ Working Party on Transfusion Associated Hepatitis. Had his early efforts received a positive response then it is likely that the results of such a study would have been available before the AABB decision in 1986. Whether an additional study would have been required in consequence of the effects of the AIDS risk on donor selection policies cannot now be known. Professor Leikola, however, was clear that he was not critical of the decision not to introduce surrogate screening into Scotland and his opinion on this matter is accepted.

**27.388** Importantly, while such a study would have led to more informed decision-making, given the difficulties discussed above that arise from using a test of such poor sensitivity and specificity to screen hundreds of thousands of donors, it cannot be concluded that had such a study been carried out at some point in the 1980s in Scotland, or in the UK, surrogate screening would, or should, have been introduced.

## Conclusions

### *The relevant period*

**27.389** The period during which consideration of the introduction of surrogate screening of blood for possible signs of NANB Hepatitis infection was a significant issue for the SNBTS and Scottish Government officials, began with the recommendations of the Council of Europe Committee of Experts on Blood Transfusion and Immunohaematology in May 1987.

**27.390** The period ended with the introduction of specific testing for antibodies to HCV on 1 September 1991.

### *Recipient populations potentially affected by the lack of surrogate testing*

**27.391** By May 1987, blood products used in Scotland for the treatment of patients with blood coagulation disorders did not expose recipients to a risk of transmission of HCV that might have been removed or alleviated by surrogate testing because:

- Commercial products imported from the USA were prepared from blood donations that were subject to surrogate testing.
- PFC Factor VIII and Factor IX concentrates were already heat-treated in such a way as to effectively inactivate any virus in the product (Factor IX DEFIX with effect from October 1985 and Factor VIII 8Y with effect from April/May 1987).

**27.392** The recipient populations potentially exposed to risks following the failure to carry out surrogate testing of donations during the relevant period were surgical, medical and other patients receiving transfusions of whole blood or blood components from donations that were not screened for elevated ALT or for anti-HBc.

### *The surrogate tests available and their effectiveness*

**27.393** Before the relevant period, research studies, mainly carried out in the USA, reported a correlation between elevated ALT levels in blood donors and an increased risk of transfusion recipients developing NANB Hepatitis.

**27.394** Other research from that time also reported an association between the presence of anti-HBc in blood donors and an increased risk of NANB Hepatitis transmission to transfusion recipients.

**27.395** These findings supported the view that elevated ALT and/or anti-HBc might be useful 'surrogate markers' for NANB Hepatitis in donated blood.

**27.396** No acceptable scientific basis for a correlation between the presence of anti-HBc in donated blood and the transmission of HCV was established on the evidence before the Inquiry and the failure to institute routine anti-HBc screening is not significant.

**27.397** In individuals, ALT levels fluctuate from time to time. There are different causes of ALT elevation, many of which have nothing to do with hepatitis, including obesity and the effects of the excessive consumption of alcohol. A single, isolated elevated test is not a reliable indicator of underlying infection.

**27.398** Generally, the poor sensitivity and specificity of ALT tests meant that the majority of infected donations were unlikely to be detected and, of the many thousands of donations that tested positive, the vast majority were likely to be false positives.

**27.399** The likelihood that ALT testing would provide an acceptable surrogate test varied from country to country. There was no guarantee that, in a given country, ALT testing would result in a significant reduction in the transmission of NANB Hepatitis.

**27.400** It was recognised in Europe that individual countries would have to assess the situation locally and decide on the appropriate action to take. In particular, the prevalence of NANB Hepatitis in the local population generally, and in the blood donor population in particular, was a significant consideration.

### *Decision-making in Scotland*

**27.401** Subject, ultimately, to Parliament's over-riding control, the decision as to whether or not to introduce ALT testing in Scotland was a matter for ministers with responsibility Scottish affairs, based on the advice of officials.

**27.402** Scottish officials were not obliged to submit the introduction of ALT testing to ministers unless they were satisfied that there was evidence and expert advice justifying the introduction of the procedure. It was part of their function to consider the evidence and advice available to them and to form a view as to whether or not to seek a ministerial decision on the issue.

**27.403** In the event, SHHD officials were not persuaded of the merits of surrogate testing and did not put the issue to ministers for a decision. As a result, ministers did not take part in the decision-making process, for which they were responsible.

### *The lack of a decision on surrogate testing*

**27.404** After the AVCSB was set up in early 1989, government, at the UK and Scottish levels, had a source of guidance from well reputed experts on which ministers and officials were entitled to rely for scientific and medical advice in formulating policy on surrogate testing. Before that time, Scottish officials had to rely on local expertise and such indirect sources as were available from the DoH.

**27.405** Scottish officials never had adequate information on the prevalence of post-transfusion NANB Hepatitis in the Scottish population or any material cohort of that population. Further, the predictive value of raised ALT levels in donors was limited, due to its known lack of specificity.

**27.406** The lack of data was the result of decisions taken in the 1980s that there should not be a large-scale prospective study of the prevalence of post-transfusion NANB Hepatitis in the UK as a whole or in Scotland in particular.

**27.407** On the evidence before the Inquiry, it was too late by the beginning of the relevant period to initiate such a large-scale prospective study. Such an exercise could not have been expected to have produced reliable results in time to inform decisions on the introduction of surrogate testing. It appears that those reliable results would not have been available before early 1990 at the earliest.

**27.408** There were conflicting expert views on many of the factors relevant to surrogate testing, including the prevalence of post-transfusion NANB Hepatitis, its potential seriousness for patients infected by the virus and the different viruses postulated as infective agents.

**27.409** It was, however, generally acknowledged that the available tests had poor sensitivity and specificity for their effective use in the mass screening of donors and that the lack of a confirmatory test meant that it would be difficult or impossible to distinguish between a true and false positive result.

**27.410** These difficulties would, in turn, have given rise to real difficulties in counselling donors and in maintaining a sufficient blood supply.

**27.411** While surrogate testing is likely to have prevented some cases of transfusion-transmitted NANB Hepatitis, it is not possible to quantify the percentage reduction with any degree of confidence, given that the prevalence of NANB Hepatitis at the time was not known and the likely efficacy of surrogate testing in reducing the transmission of NANB Hepatitis was speculative.

**27.412** With the establishment of the ACVSB in early 1989, it was reasonable for government to act on the expert advice received from that committee. The ACVSB did not, in the event, recommend the introduction of surrogate testing.

**27.413** In the final outcome, there was no definitive decision by Scottish officials whether or not to recommend the introduction of surrogate testing.

#### *Practical consequences*

**27.414** While it seems likely, on the balance of probabilities, that ALT testing would have reduced the incidence of transfusion-transmitted Hepatitis C to some extent, given all of the difficulties set out in this chapter it was not possible at the time, nor is it possible now, to say to what extent the incidence of post-transfusion Hepatitis C would have been reduced in recipients of blood and blood components by transfusion, or at what 'cost' in terms of impact on donors and impact on the blood supply.

**27.415** The Inquiry does not attribute blame for the fact that surrogate testing was not introduced, given the diversity of respected medical and scientific views over the period 1986–91. There was no consistent support for the procedure on tenable scientific or medical grounds that would have made it possible to conclude that officials should have recommended the introduction of ALT testing, or that the question was so narrowly balanced that it required to be referred to ministers for decision.

## CHAPTER 28

### DONOR SELECTION – AIDS

#### Introduction

**28.1** As indicated in Chapter 12, *HIV/AIDS: Response and Clinical Practice*, ‘donor selection’ was among the several approaches taken to minimise the emerging risk of AIDS transmission. ‘Donor selection’ refers to the steps taken by the Scottish National Blood Transfusion Service (SNBTS) and others, before testing of donations was available, to prevent the donation of blood which might carry a risk of transmission of the cause, or postulated cause, of AIDS. These steps consisted mainly of public information, to make ‘higher-risk’ prospective donors aware of the disease and the risk that it could be transmitted through blood transfusion and treatment with blood products. The intention behind the dissemination of such information was to discourage from giving blood those donors perceived to be at higher risk of carrying the infective agent. This chapter discusses donor selection in the AIDS period, 1982–85. The questions for the Inquiry included, particularly, whether these efforts went far enough and began early enough.

#### First steps taken in 1983

**28.2** It was evident that steps to deal with the perceived threat from infected donations were first taken in Scotland in the spring of 1983. In his statement,<sup>1</sup> Dr Brian McClelland, Director of the Edinburgh and South East Scotland Blood Transfusion Service (BTS) at the material time, explained that he received a copy of the *Mortality and Morbidity Weekly Report (MMWR)*, published by the Centers for Disease Control (CDC) in the USA, dated 4 March 1983. The section on ‘Current Trends’ contained an article entitled ‘Prevention of Acquired Immune Deficiency Syndrome (AIDS): Report of Inter-Agency Recommendations’.<sup>2</sup> Background information on the condition, as understood at that time, was given: over 1200 cases had been reported to the CDC from 34 states and the District of Columbia in the USA, and from 15 other countries. Over 450 people had died, the fatality rate being greater than 60% for cases first diagnosed over one year previously. Reports had gradually increased in number. Latterly, 11 cases of unexplained, life-threatening opportunistic infections and cellular immune deficiency had been diagnosed in patients with haemophilia. The article included the following recommendation:

As a temporary measure, members of groups at increased risk for AIDS should refrain from donating plasma and/or blood. This recommendation includes all individuals belonging to such groups, even though many individuals are at little risk of AIDS. Centers collecting plasma and/or blood should inform potential donors of this recommendation. The Food and Drug Administration (FDA) is preparing new recommendations for manufacturers of plasma derivatives and for establishments collecting plasma or blood. This is an interim measure to protect recipients of blood products and blood until specific laboratory tests are available.<sup>3</sup>

<sup>1</sup> Dr McClelland’s Witness Statement [WIT.003.0036]. See also Day 12, pages 3–7

<sup>2</sup> ‘Current Trends: Prevention of Acquired Immune Deficiency Syndrome (AIDS): Report of Inter-Agency Recommendations’, *Morbidity and Mortality Weekly Report*, 04 March 1983 [LIT.001.0568]

<sup>3</sup> *Ibid* [LIT.001.0568] at 0569

**28.3** The reference to ‘groups at increased risk for AIDS’ was expanded in the article. The groups were described as follows:

[P]ersons who may be considered at increased risk of AIDS include those with symptoms and signs suggestive of AIDS; sexual partners of AIDS patients; sexually active homosexual or bisexual men with multiple partners; Haitian entrants to the United States; present or past abusers of IV drugs; patients with hemophilia; and sexual partners of individuals at increased risk for AIDS.<sup>4</sup>

**28.4** It was suggested that the approach to dealing with the risk of AIDS from transfusion revealed by this article seemed to be to cast the net wider than might be strictly necessary when highlighting groups at risk, because of the priority of including those people who had to be identified. Dr McClelland agreed: it appeared to have been accepted that the criteria applied would result in the exclusion of healthy donors who happened to belong to the broadly defined groups of those being asked not to donate blood.<sup>5</sup> He explained that the inter-agency recommendation quoted was unusual and had ‘quite a tortured origin’. The FDA had not been enthusiastic to issue a statement. The prime instigator of the statement was Dr Bruce Evatt of the CDC, whom Dr McClelland described as ‘essentially the focal point of the discovery of the occurrence of AIDS in patients with haemophilia’.<sup>6</sup> Dr Evatt’s role in promoting wider knowledge of the aetiology of AIDS and encouraging an appropriate clinical response has been discussed in Chapter 11, *HIV/AIDS Aetiology*, and, briefly, in Chapter 12, *HIV/AIDS – Response and Clinical Practice*.

**28.5** In addition to the influential *MMWR* publication, Dr McClelland described the evidence which had started to emerge in July 1982, that AIDS was transmissible by blood and was therefore more likely to be due to a transmissible infectious agent than to any of the other causes then being considered. He also referred to an additional, local factor. During 1983 one or two local newspapers had taken up the suggestion that Edinburgh could become the ‘AIDS capital of the North’, relating this claim to the Edinburgh Festival and a supposed relationship between gay men and the arts.<sup>7</sup>

**28.6** In this regard, Dr McClelland was asked if, at the time of first drafting a leaflet discouraging potentially high-risk donors from giving blood in 1983, he had knowledge of possible AIDS cases in Edinburgh. He answered:

From May 1983 or possibly a little earlier, Dr Anne Smith and I were meeting with Dr Sandy McMillan, a GU [genitourinary] medicine Consultant in the Royal Infirmary of Edinburgh and Mr Derek Ogg of the Scottish Homosexual Rights Group to work out ways of communicating to gay men the message that they should refrain from donating blood. Dr McMillan would have been restrained by clinical confidentiality from mentioning any specific cases, but it is my recollection that he was aware that some of his male patients who were known to be gay were showing clinical features that suggested that they could be suffering from this new form of immune deficiency disorder.<sup>8</sup>

<sup>8</sup> Ibid [WIT.003.0036] at 0039

**28.7** Dr McMillan's remit as Consultant at the Royal Infirmary of Edinburgh (RIE) included sexually transmitted diseases and he was well known to and respected by the gay community. His recollection of events, after more than 25 years, was understandably hazy but in a letter to the Inquiry he also described meetings with members of the SNBTS, in particular Dr McClelland, and Mr Ogg of the Scottish Homosexual Rights Group (SHRG), to discuss how best to dissuade men who had sex with men from donating blood.<sup>9</sup> Open discussion in this group was to be of some importance as matters proceeded.

**28.8** Against this background, Dr McClelland began work on a leaflet.<sup>10</sup> He explained that the obvious approach at the time was to follow the principles of the US Public Health Services Interagency Guidelines, as reported in the *MMWR*, slightly adapted for use in Edinburgh.<sup>11</sup> By 24 May 1983, when the SNBTS Coordinating Group met, Dr McClelland had prepared a draft, which he tabled at the meeting.<sup>12</sup> The leaflet stated:

What is AIDS?

It is a disease called

(A) (I) (D) (S)  
acquired immuno deficiency syndrome

which is thought to be caused by an infectious agent, perhaps a virus. So far the cause is unknown. It is a rare disease but it can have serious consequences.

....

Who can get the disease?

AIDS has been occurring, particularly in the USA, in certain people who are apparently susceptible to the disease:

- 1) Homosexual men, particularly those with multiple partners;
- 2) Drug abusers;
- 3) Sexual contacts of people with AIDS – women can be infected if the males are bisexual;
- 4) Haitian immigrants to USA;
- 5) Haemophiliacs – who may be more susceptible or may become infected by their use of blood products which may have come from a blood donor with AIDS.

Most (but not all) cases have occurred in the homosexual male population. Why this should be is not yet known. A small number of young children have been affected.

....

<sup>9</sup> See Dr McMillan's comments to this effect in his letter at [PEN.014.0102]

<sup>10</sup> A newspaper article dated 20 November 1984 [DHF.001.6009] was shown to Dr McClelland, and he was asked about the comments in it by a Dr John Seale that the UK was slow in 'clamping down' on higher-risk donors. Dr McClelland did not agree, and referred to the near simultaneous commencement of the issuing of similar advice in the UK and the USA in 1983 – Day 12, pages 68–70 and Dr McClelland's Witness Statement [WIT.003.0036] at 0044.

<sup>11</sup> Day 12, page 10; Witness Statement [WIT.003.0036] at 0038. See also: 'Current Trends: Prevention of Acquired Immune Deficiency Syndrome (AIDS): Report of Inter-Agency Recommendations', *MMWR*, 04 March 1983 [LIT.001.0568]

<sup>12</sup> Meeting minutes [SNB.003.7116] at 7120

### Can it be Transmitted by Blood Transfusion?

It appears it can. This might cause the disease in people who are not normally at risk. It may have infected clotting factors that caused AIDS in Haemophiliac men in USA.

We have not had any definite cases of AIDS in Haemophiliacs in UK. If the clotting factor concentrate (factor VIII) can be infected, then cases could occur in UK because much of the factor VIII is imported to UK from USA.

The disease cannot be taken lightly. Those getting AIDS may die, because they are more susceptible to serious infections and cancer due to their impaired immune system.

The Blood Transfusion Service is therefore concerned to try and stop any chance of infection spreading by blood transfusion.

We want to ask people who may be at risk from the disease to avoid giving blood until we have a suitable screening test. Many donors will remember we did this with hepatitis until we had screening tests for the hepatitis virus.

### Whose Blood Could be a Risk?

All our information about at risk groups comes from the USA. However, until more is known about the cause and spread of AIDS, we would ask the following groups to refrain from donating blood:

- 1) Homosexual men;
- 2) Women who continually have multiple sexual partners;
- 3) Partners of bisexual men;
- 4) Anyone who abuses drugs;
- 5) Anyone who has been in contact with a case of AIDS.

We hope that if we take precautions now, we can prevent the problem of AIDS which has become serious in USA.

Remember it is a rare disease but an important one.<sup>13</sup>

**28.9** For comparison, the Inquiry examined some of the text from an early leaflet produced by the American Red Cross and apparently intended to be available at donation centres in the USA. The leaflet was entitled 'An important message to all blood donors'. The relevant section of the text is quoted at the end of a Council of Europe Recommendation, No. R(83) 8:

What are these illnesses?

Some persons may feel in excellent health but have viruses or other infectious agents in their blood that could cause illness in persons receiving a transfusion of their blood. If you think any of the following information pertains to you, please do not donate blood today:

1. *Acquired Immune Deficiency Syndrome (AIDS)*. This newly described illness of unknown cause is believed to be spread by intimate personal contact and possibly by blood transfusion. Persons with AIDS have reduced

---

<sup>13</sup> Leaflet: 'AIDS AND BLOOD TRANSFUSION: Some background to the recent publicity' [SNB.003.7153]. (Note the handwritten note in the top right hand corner which reads 'Item 15 of 24.5.83'). Council of Europe Recommendation, No. R(83) 8 [DHF.001.4550]

defences against disease and as a result may develop infections such as pneumonia, or other serious illnesses. At this time there is no laboratory test to detect all persons with AIDS. Therefore we must rely on blood donors' health histories to exclude individuals whose blood might transmit AIDS to patients who will receive that blood.

The Office of Biologics of the Food and Drug Administration has identified groups at an increased risk of developing AIDS. These groups are:

- Persons with symptoms and signs suggestive of AIDS. These include severe night sweats, unexplained fevers, unexpected weight loss, lymphadenopathy (swollen glands) or Kaposi's Sarcoma (a rare cancer);
- Sexually active homosexual or bisexual men with multiple partners;
- Recent Haitian entrants into the United States;
- Present or past abusers of intravenous drugs;
- Sexual partners of persons at increased risk of AIDS.

....

What should I do?

If you believe that you may be carrying one of the above-mentioned illnesses, or if you are an individual in a group at increased risk of developing AIDS, we ask that you refrain from donating blood at this time. You may leave now without providing an explanation. Or, if you prefer, you may proceed to be deferred confidentially, without further questioning, by the health history interviewer.<sup>14</sup>

**28.10** Dr McClelland was asked about the detail of the drafting of successive versions of the early leaflets in Scotland. He pointed out that there were various reasons for adjusting the wording:

I think ... we were probably trying to make some adjustments in the wording for two separate reasons. One was, in successive drafts, trying to come up with wording which was not more offensive to people than it had to be. Secondly, wording that was as unambiguous as we could make it, and thirdly that where we felt there might be some areas that perhaps hadn't been adequately identified in the very first version, which had come from the United States, we were prepared to try and extend a little bit more because we had the advantage of coming second, if you like.

....

[T]he fourth one, of course, was that as the months went on, new information was becoming available quite rapidly, which also we attempted to reflect as accurately as we could in successive drafts of the document.<sup>15</sup>

**28.11** At the meeting of the Coordinating Group on 24 May 1983, other Directors were asked what, if any, steps they had taken to address the AIDS risk. Dr Ruthven Mitchell, Director of the Glasgow and West of Scotland BTS, reported that he had introduced into the standard health questionnaire issued to prospective donors at West of Scotland sessions a question inviting those who were worried about AIDS to consult the doctor at the

<sup>14</sup> Information leaflet [DHF.001.4550] at 4551–52. Dr McClelland could not recall if he saw this leaflet in 1983: Day 12, page 109

<sup>15</sup> Day 12, pages 13–14

session. Professor Stan Urbaniak, then Director of the Aberdeen centre, had decided, after consideration, not to do anything locally, his view being that once a donor had entered the session it was too late to make an approach. He also thought that the problem was ‘minor’ in north east Scotland.<sup>16</sup> The responses underlined the extent to which Dr McClelland’s leaflet preparations were ahead of other regions, although as it transpired, the problem in the Edinburgh area at that time was indeed more serious than elsewhere in Scotland.<sup>17</sup>

**28.12** In the course of his oral evidence, Dr Mitchell was shown a copy of a leaflet produced by the Glasgow and West of Scotland BTS which appeared to include an early reference to AIDS. It took the form of a label or sticker attached to the bottom of the leaflet, with the following wording:

HAVE YOU HEARD OF A.I.D.S. (ACQUIRED IMMUNE DEFICIENCY SYNDROME).  
IF YOU HAVE ANY DOUBTS ABOUT GIVING A DONATION CONSULT THE  
DOCTOR AT THIS SESSION OR YOUR OWN G.P. OR WRITE IN CONFIDENCE TO  
THE REGIONAL DIRECTOR.<sup>18</sup>

**28.13** The date ‘16/6/83’ had been written at the bottom of this leaflet. Dr Mitchell had checked with his then donor manager and she could not produce any other leaflets from that time. It appears that this copy leaflet reflected the information provided by Dr Mitchell at the meeting of the Coordinating Group on 24 May 1983 and was evidence of the question added for donors in the west of Scotland in the first half of 1983.<sup>19</sup> The advice to donors concerned about giving blood was to consult the doctor at the session, as mentioned by Dr Mitchell, or to follow one of the alternatives proposed in the leaflet.

### Reaction to draft leaflets in Edinburgh

**28.14** It was apparent to the Inquiry that the text of Dr McClelland’s draft leaflet changed shortly after the meeting on 24 May 1983 and he was asked about the circumstances leading to those changes.

**28.15** A press release on AIDS had been issued by the SHRG on 21 May 1983.<sup>20</sup> One of its headlines was ‘Gays say “no” to ban on blood donors’. In its text, the release referred to AIDS as ‘an American disease epidemic’ and also recorded concern about the possible infection of haemophilia patients in the UK who relied on blood products ‘supplied in part from the United States which may be infected by AIDS’. It continued: ‘The disease has become known, wrongly, as “the gay plague”, and has also been described erroneously as sexually transmitted’. There followed a statement that there were no confirmed cases of AIDS among people with haemophilia in the UK. Under the heading ‘GAYS OPPOSE BAN ON GAY DONORS’, the release stated:

SHRG in particular and, it is thought, the majority of the gay population reject any proposals for a voluntary or compulsory ban on British gays giving blood. This last proposal is the most panic-stricken of the many strange proposals aired in recent weeks.<sup>21</sup>

<sup>16</sup> Meeting minutes [SNB.003.7116] at 7120

<sup>17</sup> The first positive HIV test results obtained in the Grampian Health Board area were from blood samples taken in 1984. By contrast, samples taken in the Lothian Health Board area in 1983 yielded 68 positive results. See table 3, page 32 within <http://www.documents.hps.scot.nhs.uk/general/review-of-communicable-diseases-1999.pdf> (last accessed 24 December 2014)

<sup>20</sup> Press statement [SGH.002.6759]

<sup>21</sup> Press statement [SGH.002.6759] at 6760

**28.16** Characterising descriptions of the disease as sexually transmitted as ‘erroneous’ was unfortunate: it was wrong in fact. The statement that there were no confirmed cases of AIDS in people with haemophilia in the UK was made in a number of different contexts in May 1983<sup>22</sup> but this, too, was incorrect. The Communicable Disease Report of the Public Health Laboratory Service (PHLS) for the week ending 6 May 1983 recorded that AIDS had been reported in a 20-year-old man with haemophilia in Cardiff.<sup>23</sup> That information was not widely known. Dr McClelland had no recollection of being aware of it at the time.<sup>24</sup> The gay community felt unfairly targeted as a vector of disease, in the USA and in the UK, but adopting an extreme position of denial was unlikely to have been helpful to their position, if maintained. It is to the credit of all involved in Edinburgh and the South East of Scotland that it was not maintained.

**28.17** The SHRG press release called for research and screening in relation to AIDS to be given greater priority and greater funding. It also called on the press to exercise restraint. Dr McClelland agreed that there had already been alarmist reports in the UK press.<sup>25</sup>

**28.18** The stance of the SHRG was modified in relation to what must have been an early version of Dr McClelland’s leaflet. A follow-up comment was published in the July/August 1983 edition of *Gay Scotland* at page 10:

SHRG secured a major success in its consultations with medical authorities by having a proposed leaflet withdrawn because it was seen as anti-gay and likely to cause panic. A revised leaflet drawn up jointly by SHRG and the South-East Scotland Blood Transfusion Service has now been agreed.<sup>26</sup>

**28.19** An agreed form of words for the leaflet was a major step forward.

**28.20** The magazine also reported that AIDS had, in fact, arrived in Scotland, with two cases ‘highly suspected’. Much of the report narrated cooperation between gay organisations in Scotland and the medical profession, both in relation to people who might have symptoms of AIDS and in relation to blood donation. It reported that a monitoring group was being set up involving Dr McMillan, the SHRG and the Blood Transfusion Service.

**28.21** Dr McClelland described the relationship between the gay community in Edinburgh and the blood transfusion service over this issue as follows:

At some point in the period between May/June of 1983 we became very much aware that there was a major issue among the gay community in Edinburgh, that they felt they were going to be stigmatised by this and that’s an issue that persists to this very day. We felt that the only way to approach this was to very positively engage with the gay community, and the people who were the spokesmen were Derek Ogg ... and a colleague of his, Nigel Cook. We actually brought in somebody who had a very good working relationship with them, which was Dr Alexander McMillan who was one of the consultants in the sexually transmitted disease department. As a result of that, we tried to work with them on the creation of a wording that they were able to endorse. As you

can see from this piece on the screen, they eventually did, and I think we were fairly clear that we were trying to get the best out of a difficult situation, and rather than producing a leaflet which perhaps had the wording that we would have chosen, that would be totally rejected by the gay community, we were trying to strive for something that could not only be accepted but endorsed, and quite a lot of work was done over that summer to ... promote this leaflet and the general approach within the gay community in Edinburgh.

So I'm sure the wording was amended possibly more than once as a result of dialogue – actually sitting round a table with these guys.<sup>27</sup>

**28.22** In a paper on donor selection produced for the Inquiry, Dr John Gillon, Edinburgh and South East Scotland BTS, observed:

This [dialogue] was extremely productive in securing the co-operation of the Scottish homosexual community, and gave rise to formal collaboration in the establishment of the Scottish AIDS Monitor Group (SAMG), an information sharing group consisting of representatives of SHRG, SNBTS and a consultant genito-urinary medicine (GUM) physician, on 22 June 1983.<sup>28</sup>

### Revised leaflet

**28.23** A leaflet dated June 1983 was the first to be deployed for use at donor sessions.<sup>29</sup> In comparison with the first draft, a simpler approach had been adopted in the leaflet to the definition of the groups at risk of the disease and the groups asked not to give blood. There was a single list of groups that appeared to be at risk of AIDS, including men who had multiple partners of the same sex, and it was said to be unknown why the members of these groups were more susceptible to the disease. The tone of the leaflet had been softened. It stated:

[U]ntil more is known about the cause and spread of AIDS, we would ask people in any of the high risk groups described above to avoid giving blood until we have a suitable screening test.<sup>30</sup>

**28.24** Dr McClelland was asked about a possible difficulty of interpretation in the reference to the group, 'men who have multiple partners of the same sex'. Dr McClelland said that there was no guidance as to what 'multiple' might mean and explained that this was a problem 'that has been discussed and explored again repeatedly'.<sup>31</sup> He emphasised the need to avoid a situation in which the precautions adopted ruled out the majority of potential donors; the question of 'how many sexual partners is too many' posed the same difficulty with heterosexual transmission.<sup>32</sup>

**28.25** The geographical concentration of AIDS in particular parts of the world also raised issues of potential racial discrimination. Dr McClelland described these questions of what to include in publications as 'the tip of a huge iceberg of unresolvable problems'.<sup>33</sup>

<sup>27</sup> Day 12, pages 20–21

<sup>31</sup> Day 12, page 27

<sup>32</sup> Ibid page 28

<sup>33</sup> Ibid page 28

**28.26** Another noteworthy aspect of the leaflet was that the answer to the question, 'Who can get the disease?' included in its list 'haemophiliacs' and 'recipients of blood transfusion'. When asked about this, Dr McClelland said:

I think by this time Dr Anne Smith and myself who drafted this, we had little doubt that the evidence that had been assembled by the CDC had to be interpreted as showing that this was a blood transmissible disease. We think we really had no doubt about that.<sup>34</sup>

**28.27** There were striking differences between the tone of this material and the information being given to people with haemophilia at this time, however, in particular a letter containing text drafted by Professor Bloom which was sent to members of the Haemophilia Society on 4 May 1983.<sup>35</sup> Dr McClelland was asked for his view:

Q. [T]he question which has been posed to us and which I'm therefore posing to you is: is there not an inconsistency between, on the one hand, people involved in blood transfusion saying that those with haemophilia, those receiving blood transfusion are at risk, even to the extent that they are asked not to donate their own blood, and the tone of this letter and other similar material, which is actually quite reassuring? This is all contemporaneous material. Is there an inconsistency?

A. Absolutely, clearly, there is.

Q. Yes.

A. I think this [the Bloom letter] is extraordinarily reassuring advice and it is one example of many very reassuring statements, as it were, risk-minimising statements, that were made over this period, which – I can't honestly say – I can't recall whether at the time I sort of scrutinised these statements and said, 'Gosh, that's very – that's a bit too reassuring'. I think our preoccupations were probably with doing our bit actually.

I think, if I was or had I been aware of this, I don't think it would have modified the text that we put in our leaflet because I think we felt our priority was trying to do whatever the available information could guide us to do to minimise the risk to patients. That was really our priority at that time.<sup>36</sup>

**28.28** The contrast in approach between transfusionists, acutely aware of their responsibility for the collection of blood, processing donations and supplying blood, blood components and therapeutic products, on the one hand, and haemophilia clinicians torn between the need to treat potentially fatal conditions and recognising the risks associated with therapy, on the other, which arises at many points in this Report, is particularly clear in the present context.

<sup>36</sup> Day 12, pages 30–31. See also Day 12, page 94 where Dr McClelland tempered his comments slightly, saying he should perhaps have said 'in my opinion inappropriately reassuring' rather than 'extraordinarily reassuring'.

### Circulation of revised leaflet

**28.29** Leaflets were again discussed at the meeting of the SNBTS Directors on 14 June 1983.<sup>37</sup> Dr McClelland is recorded as having tabled a revised version of the leaflet he had distributed at the Coordinating Group meeting on 24 May 1983.<sup>38</sup> Dr Mitchell circulated his blood donor questionnaire into which he had inserted the invitation to donors who were worried about AIDS to discuss it with the doctor at the blood donor session or to follow one of the other approaches suggested.

**28.30** At this meeting, Dr Harold Gunson<sup>39</sup> reported to the Scottish Directors on developments in England and Wales, where a leaflet drafted by Dr John Barbara was in circulation for comment and amendment and arrangements for distribution of the leaflet were under discussion. Dr McClelland updated the other Directors on his liaison with the SHRG. The meeting discussed the need to deter certain donors without causing offence to others. The Directors are recorded as noting that the Department of Health and Social Security (DHSS) were closely involved in discussions about the approach to take to high-risk donors in England and Wales and recommending that the Scottish Home and Health Department (SHHD) should have a similar involvement in Scotland.

**28.31** The next day Dr Albert Bell of the SHHD, who had attended the meeting, wrote a memorandum to Dr Archibald McIntyre, copied to Mr John Wastle, reporting on the discussions. According to the memorandum, Dr Gunson was still drafting the leaflet for England and Wales. The memorandum continued:

All the Directors present are now more aware of the complexity of the issues involved particularly in relation to the views of the homosexual community, the scope for misrepresentation by the press and the public, and the diplomacy required in presenting the AIDS issue in donor centres.<sup>40</sup>

**28.32** Dr Bell also referred to continuing issues about distribution and advised Dr McIntyre that there was no doubt that the SHHD would have to involve their Minister and could not rely solely on the views of the SNBTS. When Dr McClelland was asked specifically about the comments in the memo, he did not accept the implication that, at some earlier point, the Directors had been unaware of the complexities of the situation. He wondered if the memo instead reflected a previous lack of awareness within the SHHD of the complexity of the situation.<sup>41</sup>

**28.33** Later that day, Dr Bell wrote a second memorandum, this time to Mr Wastle in the SHHD and copied to Dr McIntyre.<sup>42</sup> Dr McClelland had informed Dr Bell that the leaflet tendered at the meeting the day before had now commenced circulation through the SHRG network. It was suggested that this appeared to have happened through some misunderstanding between the SHRG and the Edinburgh Regional Transfusion Centre. Dr Bell commented, however, that publication would seem to have demonstrated 'the acceptability of that particular presentation' to the SHRG.

<sup>41</sup> Day 12, pages 106–107

<sup>42</sup> Memorandum [SGF.001.0960]

**28.34** In his evidence, Dr McClelland expressed his view that the circulation of the leaflet was not based on a misunderstanding.<sup>43</sup> Even if the leaflet was issued earlier than some people intended or expected, he felt it was a good thing that it had happened: ‘it was the right thing [to do] to get it out there’.<sup>44</sup>

### United Kingdom-wide leaflet

**28.35** Meanwhile, work continued on a UK-wide leaflet, prepared in the DHSS, though ‘progress ... was slow’.<sup>45</sup> The NBTS version had said that ‘a person in any of the high risk groups of developing AIDS ... should not give blood even though they are in normal health ...’.<sup>46</sup> That had been amended to ask that anyone who thought they might have the disease or be at risk from it should refrain from giving blood. However, the first reaction of Mr Norman Fowler, then Secretary of State for Health and Social Security, had been that the wording was ‘too strong’ and that further revision might be required.<sup>47</sup> A meeting took place on 6 July 1983 involving the Minister of State for Health and the Under Secretary of State.<sup>48</sup> Further revision occurred and debate ensued about appropriate methods of distribution.<sup>49</sup> Ministers appeared keen on a ‘low key’ approach. When it was suggested, however, that the leaflet ‘cannot be seen as a leaflet which you read and then change your mind about giving blood’,<sup>50</sup> a medically qualified civil servant<sup>51</sup> was provoked to intervene:

I am afraid I cannot accept that the leaflet should not be seen “as a leaflet which you read and then change your mind about giving blood.” To my mind this is precisely what it is intended for although the message has had to be slightly obscured for obvious reasons. Clearly we must bow to Ministers’ wishes on the matter of handling the distribution ... but ... I am not sure that Ministers have fully understood the pros and cons.<sup>52</sup>

**28.36** The civil servant’s own view, on purely medical grounds supported by independent advice which he respected, was that the only sensible course was to send the leaflet out with call-up cards.

**28.37** By contrast, in relation to the question of ministerial involvement in Scotland, Dr McClelland said that he was:

[Q]uite confident that there was never any interference. There may have been a lot of discussion within the SHHD but we were never given any direct or indirect verbal or written instructions not to do what we were doing.<sup>53</sup>

**28.38** It is also evident from the DHSS documentation on this issue that many people were involved in the preparation of the leaflet and discussion of arrangements for its distribution. One memorandum, dated 4 July 1983, was addressed to a Mr Joyce and copied to 26 other people.<sup>54</sup>

<sup>53</sup> Day 12, page 46. See also pages 107–108

<sup>54</sup> Memorandum [SGH.002.6736]

**28.39** A leaflet for distribution across the UK was ready in September 1983.<sup>55</sup> It was in the following terms:

What is AIDS?

... AIDS is probably caused by a virus, but this is not known for certain.

Who is at risk from AIDS?

Most of the information about AIDS has come from the USA where approximately 1500 patients have been found to be suffering from the disease, up to the middle of 1983. Certain groups of people appear to be particularly susceptible; these are:

1. Homosexual men who have many different partners.
2. Drug addicts, male and female, using injections.
3. Sexual contacts of people suffering from AIDS.

It has also been found in a number of immigrants to the USA from the island of Haiti.

Patients with AIDS also seem more likely to have suffered, at some time, from various other diseases such as hepatitis B, syphilis or other sexually transmitted diseases.

....

Can AIDS be transmitted by transfusion of blood and blood products?

Almost certainly yes, but there is only the most remote chance of this happening with ordinary blood transfusions given in hospital. However, in the USA a very small number of patients suffering from haemophilia, an illness in which the blood will not clot, have developed AIDS. Haemophiliacs are more susceptible to AIDS because they need regular injections of a product called Factor VIII. This is made from plasma obtained from many donors. Should just one of the donors be suffering from AIDS, then the Factor VIII could transmit the disease.

How can the risks be reduced?

At present, there is no screening test the Transfusion Service can use to detect people with AIDS. So, until there is and until more is known about this disease, donors are asked not to give blood if they think they may either have the disease or be at risk from it.<sup>56</sup>

**28.40** In Scotland, this leaflet was issued with a press release by the Scottish Information Office dated 1 September 1983.<sup>57</sup> The press release reiterated that 'there is no conclusive proof that the disease can be transmitted in blood or in blood products'. Dr McClelland thought that the reference to 'no conclusive proof' (a line used in a number of government communications over this period) had an 'internal contradiction' in it.<sup>58</sup>

**28.41** The Inquiry examined some press comment from the summer of 1983. The *New Scientist* of 11 August 1983 referred to the forthcoming leaflet under a headline 'AIDS

<sup>57</sup> Press Notice [SNF.001.0416]

<sup>58</sup> Day 12, page 51. See the discussion on this form of words in Chapter 9, *Knowledge of the Geographical Spread and Prevalence of HIV/AIDS 1*.

Circular'.<sup>59</sup> *The Sun* of 12 August 1983 covered the same story under a headline 'Docs ban gays' blood.'<sup>60</sup> Dr McClelland agreed that the latter was likely to have been an example of the sort of coverage the SHRG had had in mind when they called for 'press restraint'.<sup>61</sup>

**28.42** It was apparent from the minutes of an SNBTS Directors' meeting on 13 September 1983 that, by that time, the leaflets were in 'fairly wide' circulation in the Scottish transfusion centres, although it was not clear if they were publicly available in Glasgow.<sup>62</sup>

### Reception of United Kingdom leaflet

**28.43** The UK Working Party on Transfusion-Associated Hepatitis discussed leaflets at its meeting on 27 September 1983.<sup>63</sup> Different centres were trying different ways of presenting the leaflets to donors. It was minuted that the Working Party had a preference for deciding a uniform approach as soon as possible.<sup>64</sup> In the course of discussion, it was noted in relation to the lack of a uniform method of distribution:

Dr Lane presented the fractionator's view that a variable approach did not provide material of uniform specification but Dr Mitchell pointed out the problems associated with any infringements of the integrity of the donor.<sup>65</sup>

**28.44** It appears that Dr Mitchell continued to resist any steps that might damage relationships between the blood transfusion service and donors.

**28.45** Further discussion of the leaflet took place at a meeting of the (Scottish) Haemophilia and Blood Transfusion Working Group on 14 November 1983.<sup>66</sup> Dr McClelland was not present at the meeting; Dr Mitchell was the only Transfusion Director present. Members of the Working Group, which comprised Dr George McDonald (SHHD) Professor John Cash, Dr Charles Forbes, Dr Peter Foster, Dr Christopher Ludlam and Dr Robert Perry in addition to Dr Mitchell, were asked for their views on the effectiveness of the UK leaflet. The minute recorded that it was felt generally that the leaflet 'had not been particularly useful'.<sup>67</sup> This comment had surprised Dr McClelland when he read it in preparing for the Inquiry:

[T]his surprised me when I read this again because I hadn't picked up from any ... informal sources a sense that the leaflet was not useful. My impression of the general view, was, 'Yes, this is something that, you know, needs to be done because this is a serious disease and we don't want people to get it'.<sup>68</sup>

**28.46** It was recorded that a few donors had responded to the leaflet by declaring that they were homosexual but that there remained a problem of how to screen out those who might present as donors in spite of the leaflet.<sup>69</sup> It is not clear who, apart from Dr Mitchell and perhaps Professor Cash, Medical and Scientific Director of the SNBTS, would have had occasion to take a practical interest in the usefulness of the leaflet. Professor Cash's

view, expressed at the meeting, was that a reprint of the leaflet should include changes and that different ways of bringing it to the attention of donors should be sought but that the method of distribution should be left to the Regional Transfusion Directors (RTDs).

**28.47** At the SNBTS Directors' meeting on 8 December 1983, which was attended by all of the RTDs, SHHD officials and Dr William Wagstaff from Sheffield, it was agreed that a more active approach to the distribution of leaflets was now appropriate.<sup>70</sup> It was felt that each donor should receive a copy, and the donor questionnaire should now include the question, 'Have you read and understood the leaflet on AIDS?'. No further action was to be taken, however, until a revised version of the leaflet had been issued. Dr McClelland agreed to produce a revised version of the leaflet for consideration by the Directors.<sup>71</sup>

### Revision of leaflets

**28.48** On 23 December 1983 Dr McClelland wrote to Professor Cash.<sup>72</sup> He reminded Professor Cash that the leaflet was not at that time being sent out to all donors and he felt that the text needed revision before that was done. The donor questionnaire had now been revised and specific questions and a specific reference to AIDS added. The questionnaire was to be completed and signed by all new and repeat donors.

**28.49** On 3 January 1984, Dr Wagstaff wrote to the DHSS about the leaflet,<sup>73</sup> enclosing a summary of feedback on three months' distribution of it. He also mentioned a perception that revision was necessary and added that Dr McClelland<sup>74</sup> was rewriting the leaflet at that time. He continued:

Since it was his original draft which formed the basis for the present "official" leaflet, I am sure it would be wise to see his new draft before going to the printers.<sup>75</sup>

**28.50** Dr McClelland duly wrote to Dr Wagstaff on 10 January 1984, enclosing his new draft.<sup>76</sup> The suggested changes were his and his alone; he had not, he noted in the letter, discussed the changes with 'the Scottish Transfusion Directors, Harold Gunson's AIDS Working Party of the CBLA Sub-Committee, the Transfusion Directors Hepatitis Working Party, or any of the other numerous groups who appear to be concerned with this problem'. Rather, the revisions had been based on discussions with colleagues at the South East Scotland BTS, of which Dr McClelland was Director, and contacts in the USA. He had also taken some ideas from the leaflet used in the New York Blood Centre. Dr McClelland indicated that he would be discussing the proposals with the Scottish Directors on 17 January 1984 and intended to send a draft to Dr Gunson.

**28.51** In view of his comment about 'numerous groups who appear to be concerned with this problem', Dr McClelland was asked about the effect of the proliferation of contributors or commentators. Whilst he acknowledged that extensive scrutiny of drafts could be very useful, he thought that the number of people involved, 'risked standing in the way of actually doing anything'.<sup>77</sup>

<sup>75</sup> Letter [DHF.001.5119]

<sup>76</sup> Letter [SNB.014.3185]

<sup>77</sup> Day 12, page 58

**28.52** On 9 February 1984, Dr McClelland attended a meeting at the National Institute for Biological Standards and Control (NIBSC) on the infectious hazards of blood products.<sup>78</sup> At the meeting, he explained the three main strategies for minimising the risk of infection. These were (i) avoidance of high-risk donor communities (such as prisons, ‘known homosexual areas’, etc), (ii) detection of clinical abnormalities by examination and careful questioning and (iii) exclusion of high-risk donors, or their blood, always allowing an ‘escape route’ for a donor who was deemed unsuitable.<sup>79</sup>

**28.53** Further concern about the need for a re-draft was evident from a DHSS memorandum dated 14 February 1984.<sup>80</sup> The memorandum appears to have been written by Dr Diana Walford and contained the observation that, ‘[i]n view of the published evidence of transmissibility of AIDS by blood transfusion, our current advice to donors could seem too lax’. The Inquiry did ask Dr Walford for a statement on these matters but Dr Walford declined to provide one.<sup>81</sup>

**28.54** A revised draft which was current in February 1984 was discussed at a meeting of the SNBTS Directors on 13 March 1984.<sup>82</sup> In their discussion on AIDS, they noted a previous agreement that the current leaflet should be sent to repeat donors with the call-up letter for their next session. Dr McClelland was to revise it and his revised draft had been circulated.<sup>83</sup> It appeared to the Inquiry that the specification of those who should not give blood was becoming simpler, with a request that people in any of the groups at risk not give blood and with the list of those at risk set out as follows:

AIDS has occurred mainly in these groups:

- Intravenous drug users
- Homosexual men
- People from Haiti and some areas of Equatorial Africa
- People who have had sexual contact with persons at risk in the above groups or with a person found to have AIDS.<sup>84</sup>

**28.55** Dr McClelland explained to the Inquiry that the thinking was to identify groups where there was actual epidemiological evidence of transmission and that those should be the groups that the Service was asking to not donate.<sup>85</sup>

**28.56** The text as it stood at 12 June 1984 was attached to the minutes of the meeting of the Directors of that date.<sup>86</sup> Some illustration of the difficulty of achieving an agreed draft is provided by the relevant paragraph in the minutes:

As agreed at the previous meeting Dr McClelland had revised the leaflet which he had drafted for circulation to blood donors with call-up letters. The revised

<sup>78</sup> Draft minutes [SNB.004.8628]

<sup>79</sup> Ibid [SNB.004.8628] at 8634. While not specified in the minutes, it appears that the ‘escape route’ typically involved accepting a suspect donation ‘for research’ or ‘not for clinical use’, enabling the collection of blood to proceed without exposing the donor to embarrassment.

draft had again received comments and a further one had been circulated with the agenda. Dr McClelland tabled another draft in substitute of the one which had been circulated and on the basis of comments made during the meeting this was again revised. (Final version attached.)<sup>87</sup>

**28.57** A printed leaflet, with text very similar to that under discussion at the meeting on 12 June 1984 and called ‘Important message to blood donors’, was published by the SNBTS during 1984, probably as the product of this process.<sup>88</sup> The leaflet explained what AIDS was, including that it was frequently fatal and could be transmitted by blood or blood products, and stated:

For the present therefore, it is important that those who belong to certain groups, who have an above average risk of contracting this condition, should not donate. These groups are:

- residents of or visitors to certain areas such as Chad, Haiti and Zaire
- sexually active homosexual men
- present or past abusers of intravenous drugs
- sexual partners, male or female, of any of the above people.<sup>89</sup>

**28.58** This leaflet is referred to in the Scottish Health Education Group leaflet, ‘Some facts about AIDS’ which bears the date ‘12/84’.<sup>90</sup> A chronology dated 30 November 1984 on actions taken in the South East Scotland to endeavour to make blood safe notes that the leaflet was published in August 1984 and was sent out with all call-up letters from 19 September 1984.<sup>91</sup>

**28.59** Additional steps were taken from November 1984 in relation to advice to donors. From the chronology referred to above, it is evident that some additional measures were implemented in the week beginning 19 November 1984. These included the re-design of the donor questionnaire so that, with effect from 26 November 1984, donors were required to sign a declaration that they had read the leaflet and excluded themselves from the AIDS risk groups. Beside the date 26 November 1984, there is a reference to the ‘established practice’ that all signatures had to be witnessed by the donor attendant.<sup>92</sup> On 29 November 1984, Professor Cash wrote to the RTDs, summarising actions required in relation to the leaflet, including that donors had to sign a statement that they had read the AIDS leaflet and, to the best of their knowledge, were not in one of the risk groups identified.<sup>93</sup> Dr McClelland was asked if these measures in November 1984 were related to the discovery of infection in patients treated only with Scottish products and he told the Inquiry that he was ‘fairly sure’ that this was the case.<sup>94</sup> Later in his evidence, he commented that the introduction of the signed statement by the donor was ‘probably one of the more important ... developments in this procedure’.<sup>95</sup>

<sup>94</sup> Day 12, page 72

<sup>95</sup> Ibid page 80

**28.60** The HIV infection of a group of people with haemophilia who had been treated at the RIE with NHS product ('the Edinburgh Cohort') is discussed elsewhere in this Report.<sup>96</sup> For present purposes, however, it is relevant to note that the 'implicated batch' (the batch of Factor VIII concentrate thought initially to have been associated with all of the cases of infection and latterly to have been associated with all but one or two of them) contained plasma collected from all five Scottish transfusion centres. Manufacture of the batch commenced on 7 November 1983.<sup>97</sup>

**28.61** At the SNBTS Directors' meeting on 11 December 1984, leaflets were again discussed, including the possibility of further re-drafting.<sup>98</sup> Dr McClelland undertook to circulate a leaflet produced by the Terrence Higgins Trust giving to homosexuals a clear explanation that they should not give blood.<sup>99</sup> Dr McClelland described the Trust as 'a very constructive organisation'.<sup>100</sup>

**28.62** By 17 December 1984, Dr McClelland acknowledged that the leaflet required to be revised again, although he considered that it would not be wise or practicable to issue another version just yet.<sup>101</sup> When he reflected on his letter in evidence at the Inquiry, however, he felt that the third proposal in his letter – changing 'sexually active homosexual men' to 'homosexual or bisexual men' – looked 'a bit like tinkering'.<sup>102</sup>

**28.63** The Inquiry also studied the process of re-drafting the leaflet involving the DHSS. The position in England regarding revision of the UK leaflet is set out in various internal memorandums. A submission seeking authority from Ministers for revision of the leaflet was sent on 10 August 1984.<sup>103</sup> That submission was approved on 16 October 1984. The minute recording the approval by the Minister of State for Health of the leaflet being revised and distributed in the manner suggested, also records an apology for the time taken to clear the documents for use.<sup>104</sup> Around this time, the Chief Medical Officer (CMO) for England and Wales requested information about the problems of AIDS and blood donations. A memorandum dated 19 October 1984 was sent in response, detailing the current situation on testing of donations and blood/plasma-related cases of AIDS in the UK. The memorandum ended with the following statement:

A leaflet advising donors from high risk groups for AIDS to desist from giving blood was issued by Regional Transfusion Centres in August 1983. Ministers have just agreed a redraft of this leaflet which strengthens the advise [*sic* – advice] and includes all practising homosexuals as being in the high risk group.<sup>105</sup>

<sup>96</sup> See Chapter 10, *Knowledge of the Geographical Spread and Prevalence of HIV/AIDS 2*.

<sup>104</sup> Memorandum [DHF.002.2208] and leaflet [DHF.001.5849]

<sup>105</sup> Memorandum [DHF.002.0040] at 0041

**28.64** Publication of the revised leaflet was then delayed until it could be discussed at a meeting of the Working Group on AIDS on 27 November 1984. At that meeting, members had only minor comments to make on the draft, which was again submitted to the Minister of State for Health for approval.<sup>106</sup> As this chronology shows, the revised version of the 1983 leaflet did not appear until January 1985.<sup>107</sup> A DHSS Circular accompanied the copy of this leaflet sent to Regional Health Authorities and Special Health Authorities.<sup>108</sup> A copy of the circular was sent to the SHHD and Dr Bell replied to explain that the SNBTS was ensuring that all donors received a copy of the revised AIDS leaflet and were asked to sign a statement that they had read it and were not in one of the risk groups.<sup>109</sup>

**28.65** When a further re-draft was being contemplated in July 1985, a memorandum explicitly recording regret at the delay which had occurred in the revision of the previous leaflet was written by someone in the DHSS.<sup>110</sup> Professor Cash also recorded his views about undesirable delays in the issue of leaflets in letters he wrote to Dr Wagstaff<sup>111</sup> and Dr Kenneth Calman<sup>112</sup> on 14 December 1990.

### Subsequent leaflets

**28.66** When screening of donated blood was introduced in October 1985, a new leaflet was given to donors in Scotland explaining that their blood would be tested and they were asked to sign a form indicating that they understood the new message.<sup>113</sup> The leaflet stated (all emphasis in original):

PLEASE REMEMBER

It is essential that although we are introducing HTLV-III testing you **MUST NOT** volunteer to give a blood donation if you are or have been:

1. A practising homosexual or bisexual man.
2. A drug abuser, either man or woman, who injects drugs.
3. Resident in or a visitor to central African countries.
4. A sexual partner of people in these groups.

**28.67** In England at this time, the standard leaflet said that those in the high-risk groups 'MUST NOT GIVE BLOOD' (capitals as in leaflet).<sup>114</sup> The high-risk groups were said to be:

1. Homosexual and bisexual men.
2. Drug abusers, both men and women, who inject drugs.
3. Haemophiliacs who have been treated with blood products.
4. Sexual contacts of people in these groups.<sup>115</sup>

<sup>115</sup> Ibid [SGH.001.8292] at 8293

**28.68** By August 1986, the South East Scotland BTS had developed a ‘Flash Card System’, whereby a card was given to donors by a member of the nursing or medical staff to read. The card read (capitals as in leaflet):

AIDS

PLEASE REMEMBER

1. ANY MAN WHO HAS HAD SEX WITH ANOTHER MAN SINCE 1977
2. ANYONE WHO HAS EVER INJECTED THEMSELVES WITH DRUGS
3. ANYONE WHO HAS EVER HAD A SEXUAL RELATIONSHIP WITH ANYONE IN THE ABOVE GROUPS

MUST NOT GIVE BLOOD<sup>116</sup>

**28.69** Dr McClelland explained that the flash card was a response to concern, which the service had held since the first leaflets, about how to ascertain that donors had read and understood the information:

The flash card was an attempt to move on a little bit from that and this was administered at the time when the donor was actually face-to-face with the member of the donor selection staff. You know, it went with the question, ‘Have you clocked this?’ ‘Have you read this?’ And, you know, ‘Are you in any of those categories?’<sup>117</sup>

### **Confidential Unit Exclusion**

**28.70** Dr McClelland was also asked about a system whereby donors could indicate that their blood should not be used. The system – referred to as ‘Confidential Unit Exclusion’ (CUE) – had been devised in the USA and catered for those who realised, once they were at a donating session, that they should not be donating, allowing them to continue through the process but mark their health questionnaire to indicate that their blood should not be used.<sup>118</sup> Although a system of this nature was tried in Edinburgh, Dr McClelland said that it had little effect:

As I recall, our experience with a version of this, which we did implement in Edinburgh, was that we seemed to have an extremely low yield. There were actually very few people who utilised the option. I think we eventually dropped it, actually.<sup>119</sup>

**28.71** Dr McClelland referred to a letter sent to him on 16 January 1985 by Dr Patricia Hewitt of the North London Blood Transfusion Centre.<sup>120</sup> Dr Hewitt commented on the considerable difficulties experienced in their West End Donor Centre in obtaining satisfactory answers to the questions posed in their questionnaire. Men were reluctant to pick up and read a leaflet on AIDS. A new leaflet, ‘Some reasons why you should not give blood’, had proved very popular, however, and the Centre provided a room where the donor could have privacy. Dr McClelland’s ‘escape route’ appears to have had some of the characteristics of the CUE approach in the USA.

## Rest of Scotland

**28.72** From the narrative of the evidence already set out, in particular relating to the efforts made to achieve progress, it appears to the Inquiry that the lead in drafting and revising leaflets for Scotland was taken by Edinburgh and South East Scotland BTS. It was obvious that the process must have absorbed a great deal of the time and energy of Dr McClelland as Director and others in that region at the time.

**28.73** In the circumstances, the Inquiry was interested to establish the position in the rest of the country. As noted above, at the meeting of the Co-ordinating Group on 24 May 1983, Dr Mitchell outlined action taken in the West of Scotland BTS which probably did not constitute effective communication to donors of risk to the recipient of blood or blood products. Professor Urbaniak explained that he did not feel it necessary to take any action in the north east.<sup>121</sup>

**28.74** Dr Mitchell was asked further questions about the position in Glasgow. He was handicapped by lack of contemporaneous correspondence from Glasgow.<sup>122</sup> In his evidence, he referred to the multitude of leaflets that were around at the time. Unsurprisingly, he remembered the general position concerning public information over the whole period of 1983 onwards, rather than the detail of individual leaflets. He was asked if, on seeing Dr McClelland's draft leaflet at the meeting on 14 June 1983,<sup>123</sup> he might have taken it back for circulation in Glasgow. He answered:

I know that in Glasgow in some places this kind of leaflet would be met with a certain amount of derision from some of the rather hard-working donors who give blood in Glasgow.<sup>124</sup>

**28.75** This response suggests that Dr Mitchell would not have distributed Dr McClelland's leaflet. It seems likely, as Dr Mitchell thought, that before the UK-wide leaflet was issued in the autumn of 1983, Glasgow would probably have been distributing the standard questionnaire with the added question on a label, asking donors if they had heard of AIDS.<sup>125</sup>

## Effect on donors

**28.76** It was evident to the Inquiry that Dr Mitchell was particularly concerned about the integrity of the donor – as he pointed out in terms at the meeting of the UK Working Party on Transfusion-Associated Hepatitis on 27 September 1983.<sup>126</sup> At that meeting it was agreed that it might be helpful if RTDs would provide details of how they got information to the attention of the high-risk groups of donors. As far as the effect of the leaflet on donors in the west of Scotland is concerned, Dr Mitchell was referred to a table prepared around the end of 1983 to record reactions in different parts of the UK. Glasgow was the only Scottish centre included in the table. The entry for Glasgow reads:

Uptake by donors averages one or two leaflets per session. A handful of donors have been resigned after volunteering information about homosexuality.<sup>127</sup>

<sup>126</sup> Meeting minutes [SNB.014.3030] at 3032

<sup>127</sup> Table [PEN.010.0305]

**28.77** More generally, of the 14 centres included in the table, only two referred to offence being caused and, in both instances, that was by handing leaflets to donors. Some other centres merely made the leaflets available. Usage ranged from 500 leaflets in three months in Cardiff, to Lancaster where an average of 9500 leaflets per month had been used, no doubt because in Lancaster the leaflets were issued when donors were called up. In his evidence, Dr Mitchell referred to complaints from hall-keepers because of the large number of leaflets left on the floor after a donating session.

They [the leaflets] weren't taken away by donors, they were dropped on the floor by donors. That can either mean two things: One, the donor had read and understood; or, two, the donor was very upset and concerned to see such a reference to what he thought or she thought had been a group of well meaning people and of which they hoped to be a member. Certainly, to be confronted with this thing which said, 'Wait a minute, maybe you are not wanted here.' They may have come miles and miles, just for the sake of doing good, to be turned away.<sup>128</sup>

**28.78** Dr McClelland referred in his statement to the fact that some Directors were very concerned about the risk of offending donors by giving too much prominence to the leaflet.<sup>129</sup> In his paper, Dr Gillon highlighted the meeting of the English RTDs on 18 May 1983, where it was minuted that the Directors rejected the option of questioning donors about their private lives.<sup>130</sup> However, Dr McClelland had 'no recollection of having to deal with major donor complaints that reached my level about any version of this leaflet or the subsequent ... questioning process'.<sup>131</sup>

**28.79** It was clear that all those connected with transfusion in 1983 and 1984 were concerned that these new measures should not alienate donors and were conscious of the sensitivity of asking donors about their sexual behaviour, an unprecedented step which there was deep-seated reluctance to take.<sup>132</sup>

**28.80** The scope for differences of opinion (valid or otherwise) about the risks of undermining blood collection was considerable. Commenting on public education leaflets available in England and Wales, warning higher risk individuals against donating, Hugh Barnes said in an article in *Nature* dated 13 December 1984:

Leaflets are, of course, only as effective as their circulation. A receptionist at a NBTS centre was recently asked why no such warning to prospective blood donors was on display. 'We did have them out', she said, 'but they frightened our customers away'. Dr Harold Gunson of NBTS admits to some haphazard distribution in the past, but promises 'efforts will be made to ensure that all donors attending the clinic receive a copy'.<sup>133</sup>

**28.81** 'Haphazard distribution' appears to be an accurate description of the situation in Scotland in 1983 and 1984. Dr Mitchell, and others of a like mind, had the capacity to frustrate the public education programme. On the other hand, Dr McClelland's experience demonstrated that there was no unavoidable problem where there was a predisposition

<sup>128</sup> Day 9, page 177–178. In his statement, Dr Mitchell described a single instance of this: [WIT.003.0033] at 0334.

<sup>132</sup> Ibid pages 24 and 42

<sup>133</sup> Barnes, 'Paper prophylaxis backfires', *Nature*, 13 December 1984 [PEN.017.0658]

to inform and a sensitive approach was adopted in making information available to prospective donors.

**28.82** A further aspect of the concern for donors was that there appeared to be fear that giving blood carried a risk of contracting AIDS. This concern was demonstrated in the responses to a series of surveys commissioned by the South East Scotland BTS.<sup>134</sup> In a revision of the leaflet in 1984, Dr McClelland introduced into a revision of the leaflet a question and answer about this, making it clear that donating blood carried no such risk.<sup>135</sup>

**28.83** These concerns about the effect on donors had a basis in experience as it evolved. Dr Gillon advised the Inquiry that there was a fall of 5–6% in the number of donations in the first quarter of 1985, necessitating an advertising campaign.<sup>136</sup>

### The donor population

**28.84** Dr McClelland was asked about the AIDS outbreak in Scotland, with particular reference to a report dated March 1993 by a Working Group convened by the CMO. This showed that, from 1984 to 1989 inclusive, among those testing positive for HIV, the largest single group in terms of mode of transmission was the group of intravenous drug users. However, as between Glasgow and Edinburgh (more precisely, Greater Glasgow and Lothian Health Board areas), of 321 people testing positive in the former area, 30% were intravenous drug users; whereas in the latter area, of 913 people testing positive, 53% were intravenous drug users.<sup>137</sup>

**28.85** Dr McClelland said that these figures showed the effect to a very large extent, in the years before testing, of the ‘Muirhouse Outbreak’. Muirhouse is an area in Edinburgh which experienced a major outbreak of HIV/AIDS in people who had a history of injecting drug use. The outbreak had an impact on Scottish statistics generally as well as locally. Dr McClelland said that the figures for HIV infection associated with intravenous drug use in Scotland were heavily biased by this one rather dramatic, highly localised outbreak.<sup>138</sup>

**28.86** The significant question was whether there would have been an overlap between the people in the outbreak described among the drug-using population and the blood donor population. Dr McClelland’s view (ultimately vindicated by scientific investigation) was that it was highly unlikely that there would have been individuals from that outbreak presenting as blood donors.<sup>139</sup>

**28.87** Dr McClelland was also asked about features of individual donors which may have made leaflets less successful, such as illiteracy or lack of fluency in English. His recollection was that such issues were not addressed in 1983.<sup>140</sup> In fact, in the chronology ‘Action Taken in S.E.B.T.S. To Endeavour to Make Blood Transfusion Safe’, one of the steps highlighted as taken with effect from the week beginning 19 November 1984 specifically referred to donors who were unable to read or were blind. In those circumstances, staff

<sup>139</sup> *Ibid* page 86. Subsequent genetic analysis of blood samples from the Edinburgh Cohort of haemophilia patients supports Dr McClelland’s view: IVDUs were excluded as sources of the infected donations. Holmes et al, ‘The molecular epidemiology of human immunodeficiency virus type 1 in Edinburgh’, *The Journal of Infectious Diseases* 1995; 171:45–53; [PEN.012.1679] at 1686. See Chapter 10, *Knowledge of the Geographical Spread and Prevalence of HIV/AIDS 2*, paragraphs 10.121–10.124.

<sup>140</sup> Day 12, page 89

had to satisfy themselves that these people understood the declaration and definition of risk groups. This was noted at the time to be 'established practice' anyway for the medical questionnaire.<sup>141</sup> Dr McClelland observed that issues of the presentation of information for those with difficulties in accessing it were less well addressed in the 1980s than they are now.<sup>142</sup> As Dr Hewitt's letter (paragraph 28.71 above) makes clear, some issues were well-recognised in London and shared with Dr McClelland in January 1985.

## Discussion

**28.88** The first questions that arise in relation to this topic are:

1. Whether steps should have been taken in Scotland earlier than May/June 1983 to alert blood donors to the risks of transmitting AIDS via donated blood and to prevent higher risk donors from giving blood.
2. Whether there were other measures which should have been adopted but were not.

**28.89** Any answer to the first question has to take account of the reality that regional autonomy meant that individual RTDs were free to adopt their own policies, an important factor that has arisen frequently throughout this Report. In the Edinburgh and South East Scotland BTS, Dr McClelland responded to the lead from the USA, where the outbreak was more advanced than in the UK, as soon as could have been expected. Advice was issued in the USA in the first months of 1983 and by May of that year Dr McClelland, Dr Anne Smith and Dr MacMillan not only had a leaflet in draft form but had established a liaison group with representatives of the SHRG to revise the advice. Dr McClelland's speed of response, and the effort he dedicated to making progress in preparing leaflets and securing the agreement of the gay community to an acceptable formula, were not universally applauded in Scotland. Dr Mitchell, in particular, did not do so. However, much that happened in Scotland, then and later, was as a result of Dr McClelland's efforts. His views were remarkably prescient and it is appropriate to recognise in this Report that, insofar as progress towards an acceptable solution was made, the credit is due to him.

**28.90** It was to become clear in time that HIV infection had already entered the blood donor population in Scotland. In 1983 blood was collected and pooled that, processed to produce Factor VIII concentrate, led to the infection of the 'Edinburgh Cohort'. As noted in paragraph 28.60, the 'implicated batch' associated with the Cohort, eventually shown to have infected the vast majority of the Cohort, contained plasma from all five Scottish transfusion regions. Sophisticated genetic analysis has shown that the infected donations probably involved were not collected from the intravenous drug using population or from those known to have been infected by heterosexual contact. So far as published, the geographical source of the donations has not been identified: they might have been collected anywhere in Scotland. Earlier cases of transfusion-transmitted infection would in due course be identified, and their sources are no better defined so far as the Inquiry's investigations have discovered.<sup>143</sup>

---

<sup>141</sup> Booklet [SNF.001.3381] at 3387

<sup>142</sup> Day 12, page 90

<sup>143</sup> Details are set out conveniently in Chapter 12 *HIV/AIDS: Response and Clinical Practice*.

**28.91** AIDS cases among coagulation defect patients occurred in all areas except the Dundee and Inverness regions. Whether or not steps taken earlier than May/June 1983 to alert blood donors to the risks of transmitting AIDS via donated blood and to prevent higher risk donors from giving blood might have been effective to prevent transmission of infection, the distribution of the leaflet in the Edinburgh and South East Scotland BTS, as revised following consultation with the SHRG, on 15 June 1983 could not reasonably have been earlier. In that area, the answer to the first question is clearly no.

**28.92** There is more difficulty with the rest of the country, so far as the evidence disclosed what happened. The position in Dundee and Inverness is not known. The problem of AIDS may indeed have been seen as 'minor' in north east Scotland at the time but the objective of the exercise was related to preventing or mitigating future risk. As to that, past experience could not be conclusive. Assessment required to take account of the magnitude of the harm that was targeted: AIDS was already known to be an extremely serious disease. The balance of opinion among transfusionists was moving towards a viral aetiology: HIV was apparently transmitted by blood. A precautionary approach to the possibility of risk required action.

**28.93** Dr Mitchell's observation about Dr McClelland's draft leaflet of 14 June 1983, that in some places in Glasgow 'this kind of leaflet would be met with a certain amount of derision...' by donors, reflects an unconstructive attitude to the use of leaflets aimed at discouraging high-risk donors. If the comment was a true reflection of his opinion of his donor population, as distinct from an observation reflecting on Dr McClelland, it was less than complimentary. One would not have expected the donor population of Glasgow, or any part of the West of Scotland region, to have responded to advice about the transmission of AIDS in that way. If they had, it would have been reasonable to expect Dr Mitchell and his colleagues to have corrected them. On any view, however, the observation disclosed an attitude that might have influenced less senior and less experienced Directors in framing their own policies.

**28.94** Dr Mitchell's own response, putting a stick-on label on his own questionnaire, was inadequate given the AIDS threat to the blood supply. Its wording was inapposite. The first sentence, 'Have you heard of AIDS ...' has no connection with the second, either textually or as a matter of substance. By May 1983 (which seems to be the likely date of adoption of the label) there would have been few people who had not heard of AIDS. That was never the issue to be addressed.

**28.95** The second sentence, 'If you have any doubts about giving a donation consult the doctor ...', was obscure. It left it open whether the prospective donor's doubts related to the risk of acquiring AIDS from the donation procedure (a misconception that was in fact entertained at the time: see paragraph 28.82 above) or the risk of passing on infection. So far as the risk of transmission of infection was concerned, it gave no guidance on who might be expected to have such doubts. It might reasonably be inferred that advice sought from the doctor at the session would relate to giving a donation, if that had been the whole advice, but reference to the prospective donor's own GP clouds that issue also. It is unclear what a GP would know about, or have concern about, in relation to blood donation. The final suggestion that the donor write to the Regional Director offered no assistance at all.

**28.96** The terms of Dr Mitchell's stick-on label gave no specification of the nature of the risk. The notice was lacking in guidance on reasons that might have been relevant to the

prospective donor's decision. In this respect the label was in marked contrast to the rest of Dr Mitchell's leaflet.<sup>144</sup> The leaflet listed, among other things, infectious diseases such as mumps, chickenpox and measles, and serious illnesses such as jaundice, asthma, blood diseases and diabetes, as conditions to be reported for consideration by the session doctor who would decide whether or not the individual would be allowed to donate blood. It was very specific about the factors that might give rise to concern.

**28.97** Dr Mitchell's sensitivity to the interests of donors, as he saw them, was highly developed. It was illustrated in his response to the pressure to discontinue collections in prisons and other penal institutions.<sup>145</sup> In relation to AIDS, and in retrospect, it appears likely that he gave those interests too much weight, given the gravity of the threat.

**28.98** The adoption of the UK-wide leaflet, with the support of the DHSS and the SHHD, put an end to controversy about whether it was appropriate to have such documents in issue. Dr Mitchell's suggestion that few were taken and that premises were strewn with discarded leaflets indicates that making leaflets available for distribution was not a sufficient solution to the problem of communicating the seriousness of the AIDS threat to recipients of blood and blood products. It required action on the part of the blood transfusion service. The resistance of an intransigent Director would have been difficult to overcome.

**28.99** Outside Edinburgh and South East Scotland BTS, an earlier initiative by the SHHD would have been required to give emphasis to the risks of transmission of AIDS by blood donation. As discussed in Chapter 17, *Blood and Blood Products Management*, the Common Services Agency (CSA)<sup>146</sup> and its sub-committees, while nominally having delegated responsibility for the SNBTS, were not proficient in technical transfusion matters. Consequently, any initiative would have had to come from the SHHD, which retained policy control over such matters.

**28.100** The SHHD recognised the regional autonomy of RTDs. Short of a major re-organisation of the service, such as was to take place many years later, there was nothing that could have been done to bring other regions into line with Dr McClelland's pioneering work in Edinburgh. Dr Mitchell was free to apply his own views within his own region in relation to advice to prospective donors.

**28.101** So far as central government action is concerned, it is impossible to avoid the conclusion that, to some extent at least, leaflet preparation and distribution were hampered by the number of interests involved. This is true of the UK revision in the course of 1984 (conceded in memorandums exchanged at the time: see paragraph 28.65 above) and also of the Scottish revision in 1984, though that at least was achieved by August. In both these instances, there were leaflets already in circulation but, to borrow Dr Perry's expression from another topic, there were points where the best was the enemy of the good. Nowhere was this more clearly demonstrated, perhaps, than in the memorandum on the matter circulated to 26 recipients. It is paradoxical that the Scots made faster progress with their leaflet, almost certainly because of the lack of government involvement, particularly when one reads the comments in the minutes of the SNBTS Directors' meeting

<sup>144</sup> Leaflet [PEN.013.1395]

<sup>145</sup> See Chapter 26, *Donor Selection – Higher Risk Donors*

<sup>146</sup> Section 19 of the National Health Service (Scotland) Act 1972 provided for the constitution of the Common Services Agency (CSA) for the Scottish Health Service with effect from 1 April 1974. Amongst its several responsibilities was the operational management of the blood services. See Chapter 17, *Blood and Blood Products Management*, paragraphs 17.23–17.25.

of 14 June 1983 where the Directors were hoping for a close involvement of the SHHD in the process. If they had succeeded, Dr Bell's comments on 15 June 1983 suggest that circulation of the leaflet, which was undoubtedly a good thing, would not have begun when it did. The involvement of government not only increased the number of those involved in an already crowded and unwieldy field, it also threatened to prioritise the wrong issues, as can be seen in the DHSS memorandums about the purpose of the leaflet.

**28.102** In the end, this was an issue which was largely practical and dependent on the knowledge and expertise of the transfusionists. It was probably inevitable that it would be thought best left to them to deal with the issue, with government kept informed, notwithstanding that the agreed approach had to accommodate the very widely differing views of individual Transfusion Directors.

**28.103** As for other participants, notably the representatives of the gay community, it looks remarkable from a current perspective that a body of lay people became so involved in the debate about a health issue. In the light of current medical knowledge, it is clear that their initial reaction to the draft leaflet was based on significant misconceptions. However, without their cooperation it is likely that the leaflet exercise would have been less successful and their involvement was, undoubtedly, to the benefit of all concerned.

**28.104** So far as the second question (whether there were other measures which should have been adopted but were not) is concerned, none of the many groups and individuals involved has suggested what else could have been done but was not done. The isolation of the virus, HIV, and the development of a screening test were investigations pursued with unparalleled vigour, in France, the USA and England in particular. The English researchers were successful in a timescale that, but for the unfortunate loss of priority described in Chapter 29, *The Discovery of HIV and the Development of Screening Tests*, almost certainly could not have been improved on. Any possible alternative approach would have been a temporary expedient, similar to the leaflet campaigns. If there had been an obvious step to take, it is not unreasonable to think that someone among those with the primary interest to make the suggestion would have thought of it.

**28.105** The second question, which was formulated in advance of the oral hearings, was designed to bring out any representations that interest groups or individuals might wish to make. There were comments critical of the lack of leaflets in languages other than English and the lack of attention to those with literacy problems. It is not possible to dismiss these comments but they perhaps reflect values that have developed much more recently than in the early 1980s. Against a background in which preparing and distributing any written advice at all was controversial, they appear to be something of a counsel of perfection. In a practical sense, adopting these suggestions could not have failed to hold up the process of production and distribution of the leaflets that were made available. In the end, in the view of the Inquiry, there was nothing more that could have been done that would have improved the situation.

## CHAPTER 29

### THE DISCOVERY OF HIV AND THE DEVELOPMENT OF SCREENING TESTS

#### Introduction

**29.1** This chapter describes the discovery of the Human Immunodeficiency Virus and the scientific research that led to the development in the UK of screening tests for infection.

**29.2** In 1986, the name 'Human Immunodeficiency Virus' (HIV) was adopted by the Varmus Committee.<sup>1</sup> Until then the virus had been known in French-inspired sources as lymphadenopathy-associated virus or immunodeficiency-associated virus (LAV/IDAV) and in US-inspired sources as human T-lymphotropic virus type III (HTLV-III). It was shown in 1984 that the viruses were the same.<sup>2</sup>

#### *The first human retroviruses*

**29.3** By the 1970s, retroviruses had been found in cats, horses, sheep, goats and other mammals and were well known to veterinary clinicians and pathologists.<sup>3</sup> In 1977, Japanese researchers investigating human diseases identified a retrovirus as the causative agent of an unusual leukaemia. Development work proceeded in the USA and the retrovirus was isolated in 1981 by Dr Robert Gallo (the principal US researcher in the area) and his colleagues at the National Institutes of Health (NIH) in the USA. They called it human T-lymphotropic virus type I, HTLV-I.<sup>4</sup> A second retrovirus was then isolated and called human T-lymphotropic virus type II, HTLV-II.

**29.4** The identification of a human retrovirus in 1977 was a 'slightly revelatory moment' for those researchers who had been expecting such a discovery but it was very much a revelation for those who had not known what retroviruses were and now came to realise that there was a new class of viruses capable of infecting humans and causing disease. Against this background, the concept that a pathogenic retrovirus was a possible disease-causing agent in humans became very prominent and topical amongst specialist virologists interested in AIDS.<sup>5</sup> Professor Andrew Lever, Professor of Infectious Diseases at Addenbrooke's Hospital, Cambridge, said that some virologists and infectious diseases specialists would have speculated, in the immediate aftermath of the first reports of AIDS in haemophilia patients, that a retrovirus similar to HTLV-I might 'fit the bill' for AIDS.<sup>6</sup>

#### *Institut Pasteur and LAV*

**29.5** Scientists at the Institut Pasteur in Paris, led by Professor Luc Montagnier, were among those who pursued that speculation. On 20 May 1983, an article was published in the journal *Science* reporting that researchers at the Institut had isolated a novel retrovirus from cultures of T-lymphocytes (a type of white blood cell which plays a central role in cell-mediated immunity) derived from the lymph nodes of a homosexual patient

<sup>1</sup> The Varmus Committee was convened by Dr Harold Varmus, Chair of the Retrovirus Study Group within the Vertebrate Virus Subcommittee of the International Committee on Taxonomy of Viruses: – last accessed 23 December 2014

<sup>3</sup> Professor Lever – Day 26, page 14

<sup>4</sup> Professor Lever's Witness Statement [PEN.015.0517] at 0518

<sup>5</sup> Ibid [PEN.015.0517] at 0518; Professor Lever – Day 26, page 13–14

<sup>6</sup> Professor Lever – Day 26, page 16; Professor Lever's report [PEN.015.0517] at 0518. HIV was thought to belong to the sub-group of retroviruses called 'lentiviruses,' although Professor Lever stated that the most recent research suggested that, while certainly a retrovirus, HIV does not properly belong to the sub-group of lentiviruses: Day 26, page 25.

('Patient 1') with signs and symptoms thought to precede AIDS.<sup>7</sup> The patient had multiple lymphadenopathies (swollen or enlarged lymph nodes). They reported that it appeared to be a member of the HTLV family. It was later recognised as identical to that subsequently isolated by Dr Gallo and his team at the NIH in 1984. Neither of the expressions 'LAV' or 'IDAV' appeared in the *Science* article. Rather, the article dealt with the possible classification of the virus as a member of the HTLV family and the differentiation of the new virus from the known viruses, HTLV-I and HTLV-II.

**29.6** The tentative conclusion of the article was that the virus belonged to a family of T-lymphotropic retroviruses that were horizontally transmitted in humans and might be involved in several pathological syndromes, including AIDS. The conclusion was uncommitted on the issue of whether the new virus was the aetiological agent causing AIDS. The 'antigen overload' alternative<sup>8</sup> was explicitly acknowledged. The article stated:

The role of this virus in the etiology of AIDS remains to be determined. Patient 1 had circulating antibodies against the virus, and some of the latter persisted in lymphocytes of his lymph node (or nodes). The virus-producing lymphocytes seemed to have no increased growth potential in vitro compared to the uninfected cells. Therefore, the multiple lymphadenopathies may represent a host reaction against the persistent viral infection rather than hyperproliferation of virus-infected lymphocytes. Other factors, such as repeated infection by the same virus or other bacterial and viral agents may, in some patients, overload this early defence mechanism and bring about an irreversible depletion of T cells involved in cellular immunity.<sup>9</sup>

**29.7** The full significance of the French discovery was not widely acknowledged in 1983. Later, Professor Montagnier commented:

Our results were still controversial ... and we had difficulty in obtaining the funding needed to better characterize the virus and develop a blood test. The tide only turned in France when Robert Gallo and his group in the United States made a similar discovery. In the spring of 1984, Gallo published more convincing evidence that HIV causes AIDS.<sup>10</sup>

**29.8** Despite the hesitancy expressed by Montagnier, there was growing interest in the scientific community in the hypothesis that transmission of a virus caused AIDS, and for some specialists the Montagnier discovery was significant. After the publication of their paper in *Science*, however, the French scientists struggled to persuade some others in the field that the virus they had isolated was indeed the cause of AIDS.

**29.9** In 2008 the Nobel Prize for Medicine was awarded to Luc Montagnier and Françoise Barré-Sinoussi (co-author of the *Science* article) for their discovery of the virus that causes AIDS. There had been controversy as to whether they or Dr Gallo's group had priority. In the opinion of Professor Robin Weiss,<sup>11</sup> the answer was clear: the French group published

<sup>7</sup> Barré-Sinoussi et al, 'Isolation of a T-lymphotropic retrovirus from a patient at risk for acquired immune deficiency syndrome (AIDS)', *Science*, 1983; 220:868–871 [LIT.001.0058]

<sup>8</sup> Discussed in Chapter 11, *AIDS Aetiology*.

<sup>11</sup> Professor Weiss was, at the time in question, employed at the Chester Beatty Laboratories, London. He is currently Emeritus Professor of Viral Oncology at UCL Medical School.

first.<sup>12</sup> It is not necessary to examine the merits of the controversy over priority any further in this Report.<sup>13</sup> Inevitably, however, against that background there were mixed reactions among scientists to the French paper. Professor Lever said that some were very convinced by it but that others were convinced only after the Gallo publication.<sup>14</sup>

**29.10** As noted in Chapter 11, *AIDS Aetiology*, some Scottish scientists may have been persuaded by Montagnier. However, the impression given overall is that, leaving aside all national prejudices, internationally there was cautious scepticism among many opinion leaders about the French research, until Gallo's announcement. The Montagnier/Barré-Sinoussi team did not have a long track record of discovering viruses.<sup>15</sup> Their work did not have the international esteem required to spark the scientific research and development that followed the work of the Gallo group.

### National Institutes of Health and HTLV-III

**29.11** Dr Gallo and his group announced their discovery on 23 April 1984.<sup>16</sup> They reported the presence of antibodies to HTLV-III in a majority of patients with AIDS and at the same time announced that they had isolated human T-lymphotropic retroviruses from patients with AIDS. Preliminary details were published in two articles in *Science* on 4 May 1984.<sup>17</sup> It was announced that a retrovirus belonging to the HTLV family and designated HTLV-III had been isolated from a total of 48 subjects, some with AIDS, some with 'pre-AIDS' and some without symptoms but in risk groups. The authors concluded that HTLV-III might be the primary cause of AIDS.

**29.12** Gallo's announcement was a turning point in developing knowledge worldwide. The evidence that people who had AIDS-like symptoms had antibodies against HTLV-III was more compelling circumstantial evidence that the virus was associated with the disease than finding the virus itself in somebody with the illness. In the latter case, the virus could have been a 'passenger', a virus to which the real AIDS virus had made the person more susceptible. Gallo's work was a major contribution to developing knowledge.<sup>18</sup> In time, the isolation and characterisation of the AIDS retrovirus enabled retrospective studies to be carried out on stored frozen blood samples from haemophilia patients, using tests for antibodies to the virus.

**29.13** With the development of HTLV-III testing, following US research leading from Dr Gallo's work, further cases of infection emerged and the discovery laid the basis for the general consensus that has prevailed ever since.

**29.14** There was soon intense research activity and an avalanche of technical papers. The characterisation of the virus as a 'true' member of the HTLV family was discussed.<sup>19</sup> The development of cell systems for the reproduction of HTLV antigen, a necessary step in

developing antibody tests, was researched in May 1984.<sup>20</sup> The high incidence of antibodies specific to HTLV-III in patients with AIDS and pre-AIDS was identified, supporting the suggestion that HTLV-III was the primary cause of AIDS.<sup>21</sup>

### Scientific response to LAV/HTLV-III in the United Kingdom

**29.15** The work of Dr Gallo's group in isolating the HTLV-I retrovirus responsible for the rare form of leukaemia reported in Japan had led to research in the UK. The work done was important in relation to later research on HIV. Professor Lever said in his report:

[M]uch of the research work that had been undertaken in isolating and characterising HTLV-1 was absolutely critical in facilitating the rapid discovery and identification of HIV. The discovery and usage of certain cell lines for isolating viruses and the discovery of growth factors for human cells were all essential prerequisites for retrovirus isolation. If HTLV-1 had not been identified when it was then the identification of HIV might have been delayed by several years.<sup>22</sup>

**29.16** For present purposes, research collaboration between Professor Robin Weiss at the Chester Beatty Cancer Research Institute and Professor Richard Tedder at the Middlesex Hospital, in a project to develop a serological assay for the detection of antibodies to HTLV-I, became particularly significant.<sup>23</sup> Professor Weiss provided Professor Tedder with infected serum and Professor Tedder's laboratory worked to develop the detection of antibodies to HTLV-I. By late 1983, this work was well advanced. As will be seen later, they subsequently used the expertise they gained in that research to develop anti-HTLV-III tests when it became clear that this virus was associated with AIDS.

**29.17** Earlier in 1983, Professor Tedder and his virology colleague Dr Philip Mortimer of the Public Health Laboratory Service (PHLS) both thought that AIDS looked like a transmissible viral infection. They had a meeting with a Department of Health and Social Security (DHSS) official, early in 1983. They explained their views about AIDS, including its similarity to Hepatitis B in terms of the group affected and the likely means of transmission, in order to see if they could assist by exploring the hypothesis that AIDS was a transmissible viral infection. Their overture was, however, rejected, and they were discouraged from promoting the 'transmissible agent' theory of the cause of AIDS.<sup>24</sup>

**29.18** The official government line at the time was that there was 'no conclusive evidence' that AIDS was transmitted by blood products.<sup>25</sup> The rejection of the scientists' approach had an important bearing on what later transpired. Briefly, development work proceeded in the non-government sector. Through their organisations, Professor Tedder and Professor Weiss obtained the intellectual property rights to their discoveries, initially in respect of HTLV-I, and were able to shape the approach to the development of screening. Progress was to be determined by the scientists, not by the UK Government.

**29.19** In France, the Institut Pasteur proceeded to develop an antibody screening test based on the LAV isolated by the work of Montagnier and Barré-Sinoussi. Professor Tedder and Professor Montagnier were in contact and, in the autumn of 1983, a courier brought to London a sample of IDAV, the name given at the time to the current version of the first French isolate. IDAV and LAV-I were both epidemic HIV-1 viruses and were in time to be identified as the same, for practical purposes. A ferry and trains were delayed and the courier left the flask in a security locker at Waterloo Station. When it was collected, the virus had died and could not be resuscitated.<sup>26</sup> Professor Weiss obtained more of the French virus in February 1984 but the London scientists had effectively lost some months of research work.

**29.20** Professor Tedder's comments capture the position:

[W]e would have been six months ahead of where we were in September 1984 in terms of the early epidemiology. We might have had a British isolate, a UK isolate, much earlier. We might have been able to work with commerce much earlier.

As a scientist, it grieves me that we lost six to nine months on the field. Had we been publishing the [Cheingsong-Popov] 1984 September paper in January 1984/February 1984, we would have presaged the entire Gallo and Montagnier disclosure in the *Science* paper of May 4th. We would have not only demonstrated the virus, in reality we would have had the break on epidemiology. And I really – I look back and some things happen and some things don't. This young man carrying a bottle of LAV1 in his hand, nobody to meet him, leaving it in a lock-up on Waterloo Station, such are things fairy stories are written about, you know? Such is life ....

I still weep about it. But, you know, we didn't do badly in the end.<sup>27</sup>

**29.21** For the purposes of this Inquiry, speculation on what might have been is not productive. However, the anecdote illustrates an important aspect of the reality of cutting edge scientific research in areas that attract the attention of several groups of researchers: priority may be determined by chance events. There is no necessary logical progression that allows one to transpose one team's success onto another's failure and reach conclusions about what ought to have happened, as distinct from what might have happened.

**29.22** As events unfolded, Professor Weiss' laboratory was the first in the UK to become involved in investigating HIV when they did eventually receive the French isolate of the virus from Dr Montagnier in February 1984.

### **The propagation medium and the selection of test format**

**29.23** At this point, it is convenient to say something about the science of testing since it has an important bearing on the differences between, and the relative merits of, the test developed by Professors Weiss and Tedder and the tests developed in the USA.<sup>28</sup> In simple terms, and in the context of AIDS, the early tests were looking for the antibody to the virus. An antibody is a protein produced by the body in response to an antigen, which

---

<sup>26</sup> Professor Tedder's Witness Statement [PEN.017.1831]; Professor Tedder – Day 49, pages 6–7

<sup>27</sup> Professor Tedder – Day 49, pages 62–63

<sup>28</sup> Ibid, pages 37–48 and 50–60. Professor Tedder explained to the Inquiry these different features of testing kits and this summary is derived from his evidence.

can be thought of as a 'foreign invader'.<sup>29</sup> The formation of an antibody in response to an antigen is a defining characteristic of an antigen. The human immunodeficiency virus – HIV – is an antigen. It stimulates the human body to form HIV antibodies. The screening systems developed at this early period targeted the HIV antibodies produced rather than the antigen. In most infections, the formation of antibodies signals the eradication of the infection.<sup>30</sup> Unlike antibodies produced against many other infective agents, however, the production of HIV antibodies does not indicate the eradication of the disease.<sup>31</sup> The presence of HIV antibodies was consistent with continuing disease.

**29.24** HIV is an intracellular parasite and can only propagate (grow) by getting into human white blood cells.<sup>32</sup> Once Professor Weiss had received a sample from Professor Montagnier in February 1984, it was necessary to propagate the virus in order to produce antigen for the test. The choice of cell line was important. That required the selection and use of appropriate white blood cells – a specific cell line – as a medium for propagation.

**29.25** When the HIV virus is released from a cell line it may carry with it components of the cells making up the line. These components may themselves cause reactions when introduced into a human recipient, eliciting their own antibodies. The cell line (known as H9)<sup>33</sup> used in the production of virus for the early US enzyme-linked immunosorbent assay (ELISA) tests was very efficient: large volumes of HIV antigens could be grown in it. However, the envelope of the cells making up the cell line (their 'lipid membrane') contained proteins other than HIV that could elicit antibodies when administered to some patients. The HIV antibody test produced using this cell medium was therefore responsive not only to HIV antibodies specifically but also to antibodies found in some normal, healthy people who had received a blood transfusion or an infusion of platelets, for example.<sup>34</sup> The test would register positive for antibodies in the case of these individuals whether or not they were infected with HIV. As a result, the risk of false positive results with tests using reagents produced by the H9 cell line was high: the cell line in which the virus was grown was itself responsible for false positive results.<sup>35</sup> The risk was inherent in the basic technology adopted at this early stage.<sup>36</sup>

**29.26** Professor Weiss' team used a different cell line, the 'CEM' cell line,<sup>37</sup> on the advice of a colleague, Professor Mel Greaves.<sup>38</sup> This avoided problems encountered with some of the tests developed in the USA. They developed the CEM cell line initially for research into HTLV-I. The CEM cell line used (and provided by them to the Institut Pasteur on licence)<sup>39</sup> did not express the antigens (in addition to HIV) typically produced by US technology.<sup>40</sup> As demonstrated by the research reported in the Cheingsong-Popov paper referred to at paragraph 29.14 above, it was less prone to false positive results and in fact yielded almost no false positive results in the 1984 research exercise reported.<sup>41</sup> A factor contributing to its success in that respect may have been that the proportion of infected individuals in

<sup>29</sup> See paper produced by Dr Peter Foster [PEN.013.1309], Glossary at 1310.

<sup>33</sup> A sub-line of the leukaemia tumour line.

<sup>34</sup> In particular, the Class-II Major Histocompatibility Complex (MHC-II) antigens (MHC Class II antigens). These are found also in women if they have had children with DR4 positive partners: Professor Weiss – Day 48, page 167

<sup>35</sup> See discussion of this at paragraph 29.29

<sup>36</sup> Professor Tedder – Day 49, pages 45–46

<sup>37</sup> The CEM cell line is associated with some forms of T-cell leukaemia and Hodgkin's disease, a cancer originating from lymphocytes.

<sup>38</sup> Professor Weiss – Day 48, pages 168–169

<sup>39</sup> Ibid page 170

<sup>40</sup> Professor Weiss' report [PEN.017.1261]

<sup>41</sup> Professor Weiss – Day 48, page 159

the donor population was lower in the UK than in the USA<sup>42</sup> but the technology does appear to have been fundamentally more satisfactory at this early stage than that typically employed by US pharmaceutical companies.

**29.27** The second difference that needs to be noted is the difference between radioimmunoassay (RIA) and ELISA tests. Professor Tedder's research work, once virus-infected material had been provided to him, led to an RIA which was considered to be working by 4 July 1984, at least for laboratory purposes.<sup>43</sup> In RIA systems, radioactive isotopes are used in the detection of the target antibody. By contrast, in an ELISA the detection element is provided chemically by an enzyme. Although this initial RIA turned out to be highly successful in the UK research studies, the Inquiry heard evidence that around this time (1984–85) the general scientific climate was turning against RIA testing because of the use of radioactive materials and the safety of staff involved in testing.<sup>44</sup> In the event, no commercial company developed an RIA for the detection of HIV antibodies<sup>45</sup> and Professor Tedder's RIA was to give way later to an ELISA test.

**29.28** A third, and highly technical, distinction relates to the test format and the difference between a so-called solid phase test and a competitive test. The distinction lies in the functioning of the tests. It is relevant in this Report only to the extent that it came to have a part in assessing the respective merits of the US solid phase tests and the Middlesex Hospital/Chester Beatty competitive radioimmunoassay test developed by Professors Weiss and Tedder (the MH/CB assay) in a competitive market.

**29.29** All of the US tests under development were solid phase ELISA tests. To be fully effective, the virus antigen had to be 'pure'. For practical purposes it was assumed that virus antigen and only virus antigen was adsorbed (condensed on the active portion of the test kit). However, as has been described in relation to the cell line typically used in the USA, the material that is applied in the solid phase test may contain antigens other than those to which the test is directed. As a result, the US model was exposed to the risk of attracting non-relevant antibodies and thereby producing false positive results.

**29.30** The commercial companies involved in developing the US tests used large vessels to propagate the virus and then purified the virus from the 'soup' in which the cells were growing. The virus then had to be further purified, pelleted and further cleaned up physically by processing through a density gradient (a centrifuge used to isolate and purify cells, viruses and sub-cellular particles). A great deal of work was involved and the complexity of the process added to the time required for development of effective test kits.<sup>46</sup>

**29.31** By contrast, the competitive test format used in the MH/CB assay did not require 'pure' antigen. It used relatively high volumes of serum and was inherently more specific in application than the US test format. It attracted criticism in the 1980s, however, on the ground that it was relatively insensitive.<sup>47</sup> For present purposes, the technical distinctions between the two approaches need not be developed further. It is, however, important to note that they were distinct and that the UK developments were able to proceed without challenge from the USA on intellectual property grounds.

<sup>42</sup> Ibid page 159. Professor Weiss suggested that this was probably true, not only in those contributing to commercial blood banks but also among volunteer donors in the USA at this time.

<sup>43</sup> Professor Tedder – Day 49, pages 15–16

<sup>44</sup> Ibid pages 65–67; Dr Dow's Witness Statement [PEN.017.1680] at 1681; Dr Mortimer's Witness Statement [PEN.017.1761]; Professor Cash – Day 48, page 136

<sup>45</sup> Dr Dow's Witness Statement [PEN.017.1680] at 1681

<sup>46</sup> Professor Tedder – Day 49, page 10

<sup>47</sup> 'Sensitivity' is a function of the test's ability to capture all cases of infection with the target pathogen. 'Specificity' is a function of the test's ability to identify only the target pathogen.

## United Kingdom research: the initial phase

**29.32** The research projects of Professors Tedder and Weiss in England, and the Institut Pasteur in France, were making progress over substantially the same period as the US research discussed below. When Professor Weiss obtained LAV from Professor Montagnier in February 1984, his laboratory was concerned to investigate the prevalence of the infection and the risks associated with it.<sup>48</sup> At that time, virological research into the disease was at an early stage of development. LAV/HTLV-III infection was a threatening and dangerous condition and funds were diverted by the two scientists from other areas of their respective institutions' research in order to begin the study. They proceeded without funding from either the Medical Research Council (MRC) or the DHSS.<sup>49</sup> They did not await the development of administrative solutions.

**29.33** Dr Gallo also provided Professor Weiss with isolates of HTLV-I, HTLV-II and, in mid-1984, provided HTLV-III for research purposes.<sup>50</sup> The US and French isolates had both been provided in terms of Material Transfer Agreements, a common format between research laboratories that restricts their use to research, stipulates that the provider accepts no liability and stipulates that the material must not be used for commercial developments.<sup>51</sup> The isolate provided by Dr Gallo was HTLV-III B, the same isolate as was provided to all scientists interested in the investigation. Montagnier provided the current version of LAV-1. Professor Tedder and colleagues started developing antibodies using the Gallo isolate and continued with that source material almost exclusively until, in about November 1984, Professor Weiss' group had produced a British isolate against which Professor Tedder's team could develop antibodies. A British test was trialled in November 1984. They propagated the antigen in CEM cells which produced better quality virus and a very high level of viral antigens trapped in the cells.<sup>52</sup> In this way, they continued to produce antigen until spring 1985. In 1984 there was little to choose between the French and US isolates and the choice of the Gallo material for research seems to have been a matter of chance.<sup>53</sup>

**29.34** The Cheingsong-Popov article of 1 September 1984 set out the first published results of that research.<sup>54</sup> In carrying out the project, the MH/CB RIA assay to detect antibodies to HIV developed by Professor Weiss and Professor Tedder was used.

## The MH/CB assay for anti-HTLV-III

**29.35** There were issues for the Inquiry whether any delay in the provision of funding by the UK government, or the US government's attitude to the use of the Gallo isolate (referred to later at paragraphs 29.41–29.43), hampered progress in developing a British screening test. It appears clear from their evidence to the Inquiry that neither factor prevented or hindered progress by Professor Tedder and Professor Weiss in laboratory-based development of the assay. As noted later, funding for scale-up to industrial production became an issue, however.

**29.36** For them, it was an incredibly difficult and busy time, with resources stretched almost to breaking point.<sup>55</sup> In some respects, in attempting to meet the demands on them, Professor Tedder and his colleagues acted in a way that would have been constrained by modern employment practices.<sup>56</sup> Professor Tedder said that Dr Rachanee Cheingsong-Popov on one occasion left the maternity hospital where she was in the early stages of labour to finish a procedure in a radioimmunoassay. She gave birth to her first son two hours after returning.<sup>57</sup> Professor Tedder was to complain in strong terms about the lack of support and funding before the end of the year (1984)<sup>58</sup> but that did not inhibit the progress of their work. The scientists were pursuing their own project not only unsupported but also uninhibited by government oversight.

**29.37** In the event, the prototype MH/CB competitive assay was ready for laboratory application on 4 July 1984. At that stage, they were ready to carry out epidemiological studies.<sup>59</sup> On 16 July 1984, Dr Ian Fraser of the Bristol Blood Transfusion Service wrote to Dr Alison Smithies, DHSS, outlining what was proposed.<sup>60</sup> He reported that a screening test for AIDS was likely to be available within the next eight weeks or so for trial, first at Edgware and then at Bristol and Manchester.

**29.38** At that stage the DHSS did not have an isolate that could be provided to a commercial manufacturer in the UK for the development of a test. The MH/CB test was beginning trials but, from the summer of 1984, Professor Tedder and his colleagues believed that they needed a much larger number of donors to be tested than those dealt with in their paper to ascertain the prevalence of HTLV-III in the donor population. For this, they required to involve a wider range of centres. Widening the project involved risk and would require control. The National Blood Transfusion Service (NBTS) was reluctant to introduce general testing because of the risk of attracting individuals seeking access to 'AIDS tests' for personal purposes.<sup>61</sup> Targeted subsets had proved problematic in other contexts. It was important to avoid attracting 'window donors', individuals who thought they had been recently exposed, who were, as Professor Tedder put it, 'bad news' for the blood component issue but could have been 'devastating' for blood products.<sup>62</sup> There was, however, a clear need to expand the research.

**29.39** It was at this stage that DHSS officials made contact with their US counterparts to ask permission to use Gallo technology for screening in the National Health Service (NHS). The DHSS was aware of the development of the RIA by Professors Weiss and Tedder from isolate supplied by Dr Gallo 'for research purposes only'. Among other aims, the DHSS was keen to commence screening of donated blood for the virus, initially at two or three Regional Transfusion Centres. To do so, as the DHSS saw it, it was necessary to obtain further supplies of the virus from the USA.

**29.40** On 10 August 1984, a DHSS official, probably Dr Walford or Dr Smithies, wrote to the Assistant Secretary for Health in Washington DC. The letter narrated the work of Professor Tedder and Professor Weiss, and the anticipated publication of their research, and stated:

<sup>60</sup> Letter [DHF.002.9126]

<sup>61</sup> Professor Tedder – Day 49, pages 71–72; Professor Tedder's report [PEN.017.1831] at 1833.

<sup>62</sup> Professor Tedder – Day 49, pages 72–74

We are anxious to extend the screening test initially to two or three of our Regional Transfusion Centres in order to establish the incidence of carriers amongst donors in a varied donor population. To do this further supplies of antigen are required over and above those that could be regarded as purely for research purposes which was the understanding on which [Dr Weiss] received the isolate from [Dr Gallo] in the first place. I am writing to request your agreement to our using the virus isolate originally provided by Dr Gallo to scale up production of the antigen.<sup>63</sup>

**29.41** It was stressed that the intention was for the isolate to be used mainly for NHS purposes. Permission was refused on 14 November 1984.<sup>64</sup> It was now clear that, outwith the boundaries of the Material Transfer Agreement entered into by Professor Weiss and Professor Tedder, the NHS was denied the Gallo isolate by the US government.

**29.42** The precise date on which the MH/CB assay was ready for routine use is not clear. It was reported to the Advisory Group on AIDS on 27 November 1984 that Professor Weiss had a UK isolate and cell line suitable for assay<sup>65</sup> but the information appears to have lacked clarity. Dr Brian McClelland, Director of the Edinburgh and East of Scotland Blood Transfusion Service, reported that he could get no clear picture of when or how a serviceable assay would be provided. Having regard to the then pending patent application in the names of the Middlesex Hospital and the Chester Beatty Laboratory,<sup>66</sup> it would have been highly unlikely that Professor Weiss and Professor Tedder would have disclosed details of their test. Professor Weiss wrote to the DHSS on 3 December 1984 confirming that he had a local independent isolate of the AIDS retrovirus.<sup>67</sup> An RIA from this isolate was also developed at the Middlesex Hospital.<sup>68</sup> Professor Weiss suggested that the use of US reagents should be stopped and that scaling-up of their methods should be developed independently. He also reported continuing discussions to expedite the development of reagents.

**29.43** The Inquiry was initially concerned to establish whether the unwillingness on the part of the US Department for Health and Human Services to allow the US isolate to be used for blood donor screening in the UK delayed the introduction of screening in this country. In fact, Professor Weiss advised the Inquiry that, by the time the reply was received from the US government, an independent isolate had already been developed by his team. Neither Professor Weiss nor Professor Tedder considered that the refusal by the US government delayed the development of a test for use in screening blood donors in the UK.<sup>69</sup>

**29.44** As regards HTLV-III antibody screening, Professor Tedder advised the Haemophilia Reference Centre Directors on 10 December 1984 that the Gallo cell line was available for research although the US government had made the isolates difficult to obtain. Looking forward, the testing of donors for HTLV-III antibody required either mass commercialisation of a British test or application of a US commercial test when that became available.<sup>70</sup>

<sup>70</sup> Notes of Meeting [SNF.001.3850]

**29.45** The approach of Professor Weiss and Professor Tedder differed from the US approach in a number of significant respects, as already discussed. Their work was now at a critical stage. In order to provide a test for general use, the laboratory-based work had to be scaled-up to industrial levels for commercial manufacture and marketing.

***Scaling-up the MH/CB assay for routine use***

**29.46** On 18 December 1984, Professor Tedder wrote to Dr Smithies:

- i. We urgently need to be able to scale-up ... the Middlesex Hospital/Chester Beatty radioimmunoassay (MH/CB RIA).
- ii. The MH/CB RIA has been designed to be compatible with the current BTS hepatitis testing. Pilot studies are of the utmost priority in selected centres to confirm this is indeed the case.
- iii. Until the MH/CB RIA has been routinely used for a considerable time, it is very important that reactive sera are referred to a designated laboratory for confirmatory testing and that donors and their blood products are followed up.
- iv. There is an initial need to monitor the efficiency with which the MH/CB RIA and the forthcoming commercial kits detect anti-HTLV III.<sup>71</sup>

**29.47** He sought financial support and commented that his Dean (Professor Sir John Pattison) and he, 'must emphasise that we see the necessary UK commitment to this problem increasing over the next few years' but that the hospital would not be able to take up the work without support.<sup>72</sup>

**29.48** On 31 December 1984, Dr Smithies, DHSS, drafted and circulated a position paper on 'AIDS and its prevention in the UK' in response to a request from the Chief Medical Officer (CMO).<sup>73</sup> She commented on the response on 14 November 1984 from the US government to the request for permission to make wider use of the Gallo isolate and noted that, by the time the response had been received, Dr Weiss had succeeded in isolating the virus from a British patient. She noted that negotiations had been opened with Wellcome (Wellcome Diagnostics, a UK pharmaceutical company) to use the UK isolate to develop a UK test, and that Wellcome had sub-contracted CAMR Porton, who had the appropriate containment facilities, to produce the antigen.<sup>74</sup> The advantages of the UK test were noted: with luck, it might be available at about the same time as the US commercial tests; it was suitable for use in RTCs which already had experience of the RIA format; it was also more sensitive and specific than the US tests; and it was likely to be less expensive.

**29.49** In addition, Dr Smithies prepared a draft submission to Ministers seeking approval for the introduction of an AIDS screening test. In sending the paper to Dr Richard Alderslade, DHSS, for consideration by the CMO, she wrote:

---

<sup>71</sup> Letter [DHF.001.8856]

<sup>72</sup> Ibid [DHF.001.8856] at 8857

<sup>73</sup> Covering letter [DHF.002.0430]; position paper [DHF.002.0431]

<sup>74</sup> Formerly the highly secretive MOD technology park DSTL Porton Down, the establishment closed as an MOD facility in 1979 and re-opened in 1980 as the Centre for Applied Microbiology and Research (CAMR) within the Public Health Laboratory Service (PHLS).

The UK test is currently being used at the Middlesex Hospital and at the Central Public Health Laboratory, Colindale to detect antibody carriers among patients thought to have AIDS or the AIDS related complex, haemophiliacs and male homosexuals attending STD clinics.

Scale up of production of the reagent is necessary before the test can be applied more widely.<sup>75</sup>

**29.50** In the event, testing of patients (particularly haemophilia patients) was already widespread by the end of 1984. From the researchers' point of view, that might have been characterised as an extension of the research project. From the clinicians' point of view it was an aspect of patient care. It had revealed that a significant proportion of English and Welsh haemophilia patients and at least 33 Scottish haemophilia patients were positive for the AIDS virus.<sup>76</sup> Professor Tedder's letter of 18 December 1984 had sought funds for development to promote donor screening, not testing of patients.

**29.51** It appears that the distinctions between 'research' testing of assays for HTLV-III by Professor Tedder and subsequent testing of wider groups, for example the haemophilia population, for antibodies to HTLV-III/HIV, may have become blurred by the beginning of 1985 so that 'patients' were beginning to be screened rather than 'research subjects' evaluated. This was probably increasingly the position in relation to the use of the initial tests based on Gallo/Montagnier isolates and subsequently in the evaluation of the test based on the UK isolate from December 1984. By early 1985 the majority of UK haemophilia patients had been tested for HTLV-III in a piecemeal fashion, without a developed protocol having been worked out and promulgated. It seems likely that, because testing arose in this way, many of the issues around informed consent and counselling which were soon to emerge were not dealt with and haemophilia doctors found themselves in possession of important information about their patients with which they were ill-prepared to deal. Practical response on the ground had run beyond official guidance. These issues are dealt with in Chapters 32 and 33.

**29.52** In addition to the two papers referred to at paragraphs 29.48–29.49, Dr Smithies prepared a further paper dated 4 January 1985 for the Research Liaison Group (a joint NBTS/BPL research group).<sup>77</sup> In it she supported Professor Tedder's application for funding.<sup>78</sup> She narrated the work of Professor Tedder and Professor Weiss in developing the MH/CB RIA, its compatibility with the BPL Hepatitis B RIA (then routinely used to screen blood donors for Hepatitis B); and the role of Wellcome, and stated:

There has been a Patent application in the names of the Middlesex Hospital and the Chester Beatty Laboratory ... and commercial exploitation is likely.

The MH/CB RIA is thus a product of the co-operation of British Science and British Industry. There is general agreement that it is the most sensitive RIA for HTLV III presently available.<sup>79</sup>

<sup>76</sup> The number of seroconversions in Edinburgh among recipients of the implicated batch was 18, as explained in the Preliminary Report, paragraph 8.207. See also Chapter 10, *Knowledge of the Geographical Spread and Prevalence of HIV/AIDS 2*.

<sup>77</sup> BPL, The Blood Products Laboratory, is the manufacturer of NHS blood products in England and Wales.

<sup>78</sup> Covering Letter [DHF.001.9040]; Paper [DHF.001.9036]

<sup>79</sup> Paper [DHF.001.9036]

**29.53** As noted above, the MH/CB RIA was, in fact, the only RIA developed for the HTLV-III antibody.<sup>80</sup> Dr Smithies drew heavily on Professor Tedder's representations in supporting further work, which she said was strongly supported by the Medical Division of the DHSS. In relation to the anticipated arrival of commercial kits, she commented that Middlesex Hospital would be uniquely qualified to assess them when they arrived.

**29.54** The expectation of officials at this stage (January 1985) appears to have been that the joint venture between academic researchers and a drug company<sup>81</sup> would lead to an RIA, developed in the UK, becoming available about the same time as the US ELISA tests would become available.<sup>82</sup>

**29.55** In terms of technology, Professor Tedder commented that Dr Smithies' information was already out of date, possibly encouraged by his letter to her of 18 December 1984. The group had already begun work on an ELISA with Wellcome in October or November 1984. His letter appears to have been drafted in the light of experience of the approach most likely to be productive of funding.<sup>83</sup> On the other hand, protection of intellectual property rights in the MH/CB assay and related work would have been a legitimate reason for caution in disclosing information, given the initial refusal by the DHSS of support for research in response to the threat of AIDS.

**29.56** The scientific research and initial development work necessary to produce a specification for a commercially marketable product had been done. Outstanding was the development work required to scale-up the project for industrial manufacture and general supply.

**29.57** As Dr McClelland explained to the Inquiry, there is a 'huge difference' between an assay which works well in a laboratory in the expert hands of research scientists, and a test which can be used for hundreds of thousands of tests daily in the sort of working environment surrounding the screening of donors.<sup>84</sup> The achievement by Professors Weiss and Tedder of a functioning assay did not mean that there was immediately a test ready for use in screening blood donors in the UK for the AIDS virus. Much further work was needed and that required collaboration with Wellcome and their sub-contractors CAMR Porton.

**29.58** The scaling-up of the project and progress towards commercialisation are discussed in Chapter 30, *Screening of Donated Blood for HIV*.

## CHAPTER 30

### SCREENING OF DONATED BLOOD FOR HIV

#### Introduction

**30.1** This chapter deals with the general introduction of screening of donated blood in the UK for the AIDS virus, HIV. Although adopted later than many of the events discussed in this chapter, the name HIV is used in the narrative, except where context requires the use of one of the alternative historical names for the virus, since it is now well understood that the various names used historically (such as HTLV-III and LAV) referred to the same virus. The introduction of the screening of donated blood for HIV was dealt with in the Preliminary Report at paragraphs 8.122–8.139. Since the writing of that section, the Inquiry has obtained more information about the process which led to the introduction of screening for HIV and has perused more documents. The account which follows is therefore fuller than the account in the Preliminary Report and varies from it in part.

**30.2** Screening for HIV infection was designated as a topic which required to be considered at the Oral Hearings of the Inquiry. The topic was described as follows:

The decision not to use kits from the United States of America for testing donated blood for the virus as soon as they became available but, instead, to follow a process of evaluation of the kits before any such use.

**30.3** As defined, the topic focused on tests developed in the USA, reflecting a view held by some interested parties that progress there provided criteria against which to measure what happened in the UK in general and Scotland in particular. As the discussion in Chapter 29, *The Discovery of HIV and the Development of Screening Tests*, shows, however, the position was altogether more complex and there had been significant developments in knowledge in France and the UK in 1983 and early in 1984. It is appropriate, nonetheless, to deal with the development of screening in the USA in the first instance, since there was, on the part of some parties, a clear conception that the perceived leadership of the USA in this area was of central importance.

**30.4** While the topic was originally narrowly expressed, the hearings were not, in the event, restricted to decision-making in relation to the evaluation of kits but also examined, so far as practicable, the whole sequence of events leading to the introduction of screening of donors. It was clear from the evidence before the Inquiry that a significant focus in the UK in the second half of 1984 was on developing a British test to screen blood donations for AIDS. Whether that took priority over the introduction of US test kits became a significant question. The Inquiry has not sought direct evidence from US scientists and clinicians involved in research and development of test kits in the mid 1980s but has relied on indirect sources in narrating material events, in particular published material. Where secondary sources are relied upon, the facts have not been independently validated.<sup>1</sup>

**30.5** In summary, the issues covered in this chapter are: the development of HIV test kits in the USA following Dr Robert Gallo's announcement that he had identified the AIDS

---

<sup>1</sup> The Inquiry has drawn on information in John Crewdson's book, *Science Fictions* (2002; London: Little Brown & Co) [PEN.017.0568]. Crewdson was a journalist formerly of the Chicago Tribune. His book was cited extensively by Dr McClelland in his statement [PEN.017.1337] at 1361 and in evidence on Day 50, pages 69–79. Professor Weiss had reservations about some aspects of Crewdson's book, specifically where it attributes emotions to those quoted and discussed after the fact (Day 48, pages 151–2). Those reservations are accepted. Leaving aside Crewdson's comments, his account of events was accepted as generally accurate.

virus in April 1984; the steps taken prior to the introduction of testing in the UK, including evaluation of all available kits; Government involvement in the decision-making process; and, finally, the issue of whether matters could have been handled more expeditiously. Issues related to the identification of the virus, the initial development of the British test and the nature of the tests are discussed in detail in Chapter 29, *The Discovery of HIV and the Development of Screening Tests*, and are referred to in this chapter only where necessary to provide context.

**30.6** The period covered in this chapter runs from early 1984, when it was understood that serological tests for antibodies to HTLV-III were likely to become available imminently, until October 1985, when routine screening of blood donations for antibodies to HIV was introduced throughout the UK. It was a time when many issues regarding the screening of blood for HIV infection were being progressed simultaneously.

## The development of tests in the United States of America

### *Initial reaction to the isolation of HTLV-III*

**30.7** In the USA, reports of Dr Gallo's isolation of HTLV-III<sup>2</sup> immediately acquired a high political profile. On 23 April 1984, a press conference was held in Washington DC, involving Dr Gallo and Margaret Heckler, the US Secretary of State for Health and Human Services. At the press conference, Ms Heckler predicted that a test to screen the blood supply with 100% certainty would become widely available within six months.<sup>3</sup> This was to prove over-optimistic: on the evidence available to the Inquiry, it was to be some time before an acceptable test was developed.

**30.8** A period of intense activity sponsored by the US Federal Government followed the announcement of Dr Gallo's work. A notice in the *Federal Register*, the official journal of the federal government of the USA, dated 3 May 1984, invited proposals for the manufacture of a blood test for HIV.

**30.9** On 14 June 1984, the journal *Nature* reported that the companies selected by the US government to manufacture a blood test for HIV were expected to be announced that week.<sup>4</sup> The chosen companies would be provided with Dr Gallo's method for mass-producing the virus in return for a royalty payment, expected to be 5%.<sup>5</sup> Five companies were chosen by a committee of the Department of Health and Human Services.<sup>6</sup> Of these, Abbott Laboratories, thought by Crewdson to be the most formidable competitor, had links with the Scottish National Blood Transfusion Service (SNBTS) in Glasgow and the West of Scotland and development of the Abbott test was particularly relevant to the course of events in this country. As anticipated, they were given the then-current version of the isolate, HTLV-IIIB, in return for a royalty payment. *Nature* reported that members of the scientific panel said that they had given emphasis to the ability to manufacture the product quickly and in large quantities, as millions of test kits would be required annually.<sup>7</sup> None of the companies, however, achieved the goal set by Ms Heckler: by the end of October 1984, Ms Heckler's deadline, no test to screen the blood supply was widely

<sup>2</sup> See Chapter 29, *The Discovery of HIV and the Development of Screening Tests*, paragraphs 29.11–29.14

<sup>3</sup> See the narrative of events given at the commencement of proceedings on Day 48, pages 6–8. The press conference is also described by Douglas Starr in *Blood* [LIT.001.2936] at 2968.

<sup>4</sup> Budiansky S, 'NIH to License HTLV', *Nature*, 14 June 1984; vol 309 [SGH.002.6605]. This cutting was distributed within the DHSS with a note asking if testing would be done routinely in the UK and, if so, whether US kits would have to be bought for that purpose.

<sup>5</sup> Crewdson, J. *Science Fictions* [PEN.017.0568] at 0572

<sup>6</sup> *Ibid* [PEN.017.0568] at 0572

<sup>7</sup> Budiansky S, 'NIH to License HTLV', *Nature*, 14 June 1984; vol 309 [SGH.002.6605]

available. Abbott and other licensees were still field-testing their screening kits, enzyme-linked immunosorbent assays (ELISAs),<sup>8</sup> in cities where significant numbers of potential blood donors were presumed to be infected with the AIDS virus.<sup>9</sup>

**30.10** In order to understand developments in the USA, it is necessary to have some regard to the structure of the blood services complex in that country. In 1974, the Federal Government had published a National Blood Policy, reflecting the national interest in assuring an adequate and safe supply of blood.<sup>10</sup> The policy set out a broad statement of goals with respect to blood collection and distribution. No legislation was enacted, however. Rather, the Federal Government accepted and partially funded a private sector plan to establish an American Blood Commission to implement most of the objectives of the National Blood Policy. The American Blood Commission had no powers of enforcement and became, rather, a forum for discussion, and in many cases resolution, of blood banking issues among the private sector components of the blood services complex in the USA.<sup>11</sup> The regulation of health and safety, including blood collection and distribution, remained primarily a matter of local concern, as it had been historically.<sup>12</sup>

**30.11** The advent of AIDS prompted a new Federal initiative. In March 1983, the Food and Drug Administration (FDA), in consultation with the major blood banking and plasma derivative organisations, the National Hemophilia Foundation, the National Gay Task Force, the Centers for Disease Control and the National Institutes for Health, issued recommendations to initiate, among other measures, educational programmes to promote self-deferral and expanded medical screening of blood and plasma donors.<sup>13</sup>

*'The psychic costs to donors labelled as suspect': the problem of false positive results*

**30.12** As of May 1984, the FDA Blood Products Advisory Committee was considering whether specific 'surrogate' tests<sup>14</sup> should be instituted for all whole blood and plasma collections.<sup>15</sup> At that stage, such testing had been initiated in some centres, with two types of surrogate tests in use: (i) detection of abnormalities associated with AIDS or the preclinical stages of AIDS and (ii) evidence of past infection with diseases that had a high prevalence in population groups that were at increased risk of AIDS. A high level of false positive results (where the test result for the surrogate marker was positive but the AIDS virus was not, in fact, present: a frequent problem with any surrogate test) had been tolerated with surrogate testing for the AIDS virus. It was commented in January 1985 that:

Current surrogate tests lead to exclusion of far more donors than are ever expected to actually have or develop AIDS, and seem to have been instituted more to allay patients' and physicians' fears rather than in hopes of decreasing exposure to AIDS.<sup>16</sup>

<sup>8</sup> ELISA tests use an enzyme to detect antibodies in a sample and include various reagents which give a colour reaction. Dr Dow – Day 4, pages 85–86; Professor Weiss, Day 48, pages 160–161

<sup>9</sup> Crewdson, J. *Science Fictions*, page 185 [PEN.017.0568] at 0589

<sup>10</sup> See Blood Policy & Technology (Washington, DC; US Congress Office of Technology, OTA-H-260 January 1985) [LIT.001.4558] at 4566. The policy was National Blood Policy: US Dept. of Health, Education and Welfare. Fed Reg 1974; 39(47): part 3.

<sup>11</sup> Ibid [LIT.001.4558] at 4566

<sup>12</sup> Hillsborough County v Automated Medical Labs 471 U.S. 707 (1985)

<sup>13</sup> Blood Policy & Technology (Washington, DC; US Congress Office of Technology, OTA-H-260 January 1985) [LIT.001.4558] at 4576

<sup>14</sup> A surrogate test detects a 'marker', a directly measurable physical entity that has a statistical association (correlates) with a disease where it is not possible to test directly for the disease or where any direct test would be problematic. See Chapter 27, *Surrogate Testing of Donated Blood for non-A, non-B Hepatitis*.

<sup>15</sup> Blood Policy & Technology (Washington, DC; US Congress Office of Technology, OTA-H-260 January 1985) [LIT.001.4558] at 4576

<sup>16</sup> Ibid [LIT.001.4558] at 4579

**30.13** It was recognised that the approach adopted was detrimental to the interests of donors:

[T]he psychic costs to donors labelled as suspect have been subordinated in order to reduce the psychic costs of potential and actual recipients and their physicians.<sup>17</sup>

**30.14** It is against that background that the announcement of Gallo's findings, and the race to produce HIV tests, has to be understood. It was expected that the balancing of interests would be the same with direct laboratory tests for the AIDS virus as with surrogate testing. In the paper published in January 1985 already referred to, it was commented in relation to prevailing practice that:

The criterion used in decisions to institute these programs appears to be whether the added costs can be handled, not whether in fact AIDS will be reduced. *However, these decisions seem entirely compatible with public reaction to the threat of AIDS in the blood supply. The risk is very small, but the fear is great, and the perception that something is being done is important to public confidence.*

*A highly accurate, AIDS-specific test should decrease the perceived need for adopting any of the surrogate tests that have been proposed, but reassuring the public will probably mean that these tests can also be expected to be applied far beyond the application that would be scientifically justifiable.*

....

Thus, it can be expected that the test for HTLV-III will be a requirement for all blood and plasma collections, regardless of the relative degree of risk among blood banks and geographical areas. Even if not required for all, blood banks and plasma collectors will feel compelled to perform the test anyway because of the public confidence factor and the threat of lawsuits.<sup>18</sup>

**30.15** Testing of all blood donors for HIV was expected to become a general requirement, not conditional on scientific proof of its effectiveness. It was concluded that the prudent course was to continue with the cooperative arrangements in-hand and to monitor key developments. Discussion placed emphasis primarily on the safety of the recipient. The paper noted that blood banking and commercial plasmapheresis organisations were 'currently grappling with the social and ethical issues surrounding the imminent availability of the blood test'<sup>19</sup> but there was no explicit recognition of a duty of care towards donors such as underlay the UK approach to blood collection.

**30.16** By 1990, the official position had not changed. The disadvantages to donors in tolerating large numbers of false positives was, however, discussed in an article for the journal *Transfusion* by Dr Merlin Sayers of the Puget Sound Blood Center, Seattle, entitled *Duties to Donors*.<sup>20</sup> He expressed the view that blood bankers had inescapable responsibilities to donors. In respect of the implications for the donor, the article said:

---

<sup>17</sup> Ibid [LIT.001.4558] at 4579

<sup>18</sup> Ibid [LIT.001.4558] at 4579–80 (emph. orig.)

<sup>19</sup> Ibid [LIT.001.4558] at 4605

<sup>20</sup> Sayers, 'Duties to Donors', *Transfusion*, 1992; 32/5:465–466 [PEN.017.0649]. Though published in 1992, the article was originally submitted in January 1990.

What can be done about the 'nonspecificity trap'? In this context, heavy reliance is placed on laboratory testing in pursuit of the risk-free blood transfusion. This emphasis is not surprising, if one bears in mind the extent to which our society has enshrined technology. Though there is a beguiling simplicity in the idea that a test that could even slightly enhance transfusion safety should be implemented, technology-driven donor screening carries a price.

As 100-percent specificity does not exist, at least not side-by-side with 100 percent sensitivity, some donors have had to contend with false-positive results. As more screening tests are introduced, so will their ranks be increased. This does not bode well for anxious donors or for blood bankers trying to explain why, if some test results really are false, donation is still forbidden. Concepts such as test sensitivity, test specificity, and indeterminate results are difficult to translate into lay terms. There is scant enlightenment, let alone consolation, for the donor deferred with a 'false-positive' result ....<sup>21</sup>

**30.17** Sayers' article reflected concern, continuing in 1990, that the interests of the US donor were not taken fully into account. The more-or-less exclusive emphasis in US practice on the interests of the recipient (and of the industry, ever-anxious about exposure to litigation) is relevant to the acceptance of a high incidence of false positive results as HIV tests were rolled out in the USA, first for evaluation and then commercially. The problem in the UK relating to the efficacy of the tests was similar, although the solution was to be different and took time to develop. An issue for the Inquiry was whether the introduction of testing for HIV was unduly delayed and whether the interests of donors came to be a factor in the developing picture.

**30.18** Once testing began in the USA, problems with false positive results were evident. Abbott's product licence application, dated 19 December 1984, disclosed that, of 42 positive tests from 7758 samples, 17 proved to be true positives and 25 proved to be false, a false positive rate of about 60% relative to the initial positive results.<sup>22</sup>

**30.19** On 13 December 1984, *Nature* reported that the 'crash effort' by the Public Health Service to develop a blood test for AIDS had run into difficulties.<sup>23</sup> The article referred to significant variations in the sensitivity and specificity<sup>24</sup> of the tests being developed by the five contractors and to the suspicion that the tests were subject to significant false positive and false negative rates. Scrutiny of the performance of the kits had not been assisted by the fact that each company had received a different set of 6000 samples. Each company had run its own ELISA test and then its own confirmatory test (all using Western blot technology), complicating the interpretation of their findings.<sup>25</sup>

### *The pressure to introduce screening grows*

**30.20** Despite these problems, US government agencies pressed forward with arrangements for the introduction of screening. On 11 January 1985, the *Morbidity and*

<sup>21</sup> Ibid [PEN.017.0649]

<sup>22</sup> Crewdson, J. *Science Fictions*, page 567, footnote 'e' [PEN.017.0568] at 0598

<sup>23</sup> Budiansky S, 'False Test Results Raise Doubts', *Nature*, 13 December 1984; 312:583 [PEN.017.0658]

<sup>24</sup> 'Sensitivity' is a function of a test's ability to capture all cases of infection with the target pathogen. 'Specificity' is a function of a test's ability to identify only the target pathogen.

<sup>25</sup> The article drew on comments by Dr John Petricciani, head of the FDA's division of blood and blood products. Petricciani and colleagues from the public service published a short report of their findings in a letter, 'An analysis of serum samples positive for HTLV-III antibodies', to the *New England Journal of Medicine* vol 313. no 1 47-48, 4 July 1985 [PEN.017.0651]

*Mortality Weekly Report (MMWR)*<sup>26</sup> published Provisional Public Health Service Inter-Agency Recommendations for screening donated blood and plasma for antibody to the virus causing AIDS,<sup>27</sup> anticipating that tests would be licensed and commercially available in the USA 'in the near future'. The recommendations provided that all donors should be told that their blood would be tested for the virus and that they would be notified if the test was positive. The article commented on the efficacy of the US kits expected to be available, stating:

In the early phases of testing a number of false-positive tests may be encountered. Adjustments in interpretation are anticipated as more is learned about the performance of the test in an individual laboratory and about the specific proportion of falsely positive or falsely negative tests in the screening setting where the test is used.<sup>28</sup>

**30.21** The proportion expected to be false positives was not disclosed. However, the article noted:

When the ELISA is used to screen populations in whom the prevalence of HTLV-III infection is low, the proportion of positive results that are falsely positive will be high.

**30.22** Repeat and alternative testing systems were recommended before the donor was notified of a positive result. At the end of January 1985, Ms Heckler said that AIDS test kits would be licensed by the FDA by mid-February.<sup>29</sup> When this did not happen, Ms Heckler explained that the FDA needed more data from the manufacturers.

**30.23** In the article in *Nature* dated 13 December 1984, Dr Peter Page, Director of the American Red Cross, was quoted as having expressed concern that political pressure was rushing the process so much that there was no time to resolve the problems of false positive results that were arising.<sup>30</sup> Dr Page thought that, having regard to improvements in the blood supply brought about by appeals to high-risk groups to abstain from donating, there was no compelling case to rush ahead with blood tests. The conclusion of the article, by Stephen Budiansky, was that the ELISA test might prove to be problematic, a marked contrast to the government's push for the introduction of testing.

### *The introduction of screening in the USA*

**30.24** The Abbott test was licensed on 2 March 1985. Ms Heckler again made the announcement. According to Crewdson, the first blood bank in the world to get the AIDS test was the Red Cross Blood Center on Ohio Street in downtown Chicago. A leaflet with the kits contained a warning that 'false positive test results can be expected with a test kit of this nature'. Crewdson also reports that, at this point, Abbott only had 60,000 ELISA kits on hand, which was not nearly enough to fill the nationwide demand.<sup>31</sup>

<sup>26</sup> The *MMWR* is published by the Centers for Disease Control and Prevention (CDC), a US government public health agency with its headquarters in Atlanta, Georgia.

<sup>27</sup> 'Provisional Public Health Service Inter-Agency Recommendations for Screening Donated Blood and Plasma for Antibody to the Virus Causing Acquired Immunodeficiency Syndrome', *MMWR*, 1985; 34/1:1-5 [SNB.004.9195]

<sup>28</sup> *Ibid* [SNB.004.9195]

<sup>29</sup> Crewdson, J. *Science Fictions* [PEN.017.0568] at 0589

<sup>30</sup> Budiansky S, 'False Test Results Raise Doubts', *Nature*, 13 December 1984; 312:583. [PEN.017.0658]

<sup>31</sup> Crewdson, J. *Science Fictions* [PEN.017.0568] at 0591. The date of the announcement must have been 2 March, the first Saturday in the month, having regard to the timing of the licence granted to Electro Nucleonics Inc.

**30.25** More licenses followed in quick succession. A second US test, the 'Virgo' test manufactured by Electro-Nucleonics Inc, was licensed on 7 March 1985<sup>32</sup> and in May 1985 a US patent was granted to the US National Cancer Institute for their ELISA HIV test. Testing of blood donations was introduced in the USA in April 1985 and by the summer there were six brands available in the USA. Dr Thomas Zuck, a haematologist, was the FDA official in charge of monitoring the performance of the AIDS test. He is reported by Crewdson to have believed that the decision to grant licences had been made in haste.<sup>33</sup> Initial supplies were still not sufficient to meet demand in the domestic market.

### *Difficulties with the first generation of tests*

**30.26** One source of difficulty with the first generation of tests was the cell line, H9, in which the virus had been grown.<sup>34</sup> A more technical explanation is set out in Chapter 29, *The Discovery of HIV and the Development of Screening Tests*. In short, the cultivated virus released from the cell in which it had been growing for the purpose of test manufacture took with it certain human proteins from the membrane of the cell. Those human proteins stimulated an antibody response in some groups of individuals. Thus those individuals tested positive, although the positive result indicated antibodies to foreign proteins *other* than HIV.<sup>35</sup> The problems persisted and ultimately the FDA intervened to require Abbott to improve the specificity of its test.<sup>36</sup> As well as the problem of false positives, the Abbott test also gave false negative results.<sup>37</sup>

**30.27** The 'pure' antigen required for effective operation of the US ELISA tests had proved difficult to achieve with HTLV-IIIb grown in the H9 cell line and some highly unsatisfactory outcomes from the use of the early ELISA tests were reported. Professor Richard Tedder, Professor of Medical Virology at UCL Medical School, London, provided an extreme example from 1985 relating to an epidemiological survey of malaria among Ugandan children. The children were bled and tested for HTLV-III by Dr Carl Saxinger and Dr Gallo. The results purported to show that 85% of the children were HTLV-III antibody positive although none had, in fact, been exposed to the virus. The antigen used was not 'pure' HTLV-III: it included other proteins that were recognised by the test and erroneously characterised as HTLV-III. The children's history of malaria would have caused their plasma to be more 'sticky', resulting in proteins other than the target, HTLV-III, adhering to the antigen on the plastic strip used in the test, resulting in a false positive result.<sup>38</sup>

**38.28** Some of the practical problems caused in the USA by this flaw in the tests are outlined by John Crewdson in his book on the history of AIDS research, *Science Fictions*.<sup>39</sup> For example, the Red Cross blood centre in Springfield, Illinois, had elicited 200 positive results after one round of testing but, when those donors were re-tested with another ELISA, only 86 remained positive. Of those 86, Western Blot testing revealed that only two were true positives.<sup>40</sup> Crewdson provided another extreme example: a group of black

farmers in South Carolina, whose risk for AIDS was virtually zero, exhibited a false positive rate of 300% (that is, there were three false positive for every true positive).<sup>41</sup>

### *Supplies of test kits*

**30.29** According to Crewdson, Ms Heckler reported in mid-April 1985, at an international AIDS conference at the Centers for Disease Control (CDC), that the domestic backlog of supplies had been filled. She said:

As a result ... our manufacturers will now be able to turn their attention to *your* needs – meeting the foreign demand for the test, which has been significant ....<sup>42</sup>

**30.30** As the situation was understood by Crewdson, however, at this stage Abbott still could not make enough tests to satisfy the domestic demand.<sup>43</sup>

### *Lack of supplies for export*

**30.31** An arrangement for cross-approval of test kits between France and the USA (whereby US tests would be approved in France and French tests approved for use in the USA) could not be brought into effect as had been intended in May 1985. At the time, Abbott still did not have enough tests to supply the US market, much less the French. The company intended to meet European demand from a factory in Delkenheim, Germany. In the event, the factory did not begin production until the autumn of 1985.<sup>44</sup>

**30.32** It is noteworthy that, as at 11 March 1985, there were no Abbott kits available in the UK for general use. A small quantity was being imported so that some preliminary examination of the kits and apparatus could occur.<sup>45</sup> With the information now available, the comment in the Preliminary Report (paragraph 8.139) that kits manufactured by US companies were 'available' in March 1985 requires to be qualified by the observation that it appears that these kits were not near to being available in sufficient numbers in the UK to have allowed general screening of donated blood to commence.

**30.33** The capacity of other manufacturers to meet demand is not known. Abbott's capacity was taken generally to be the appropriate reference for discussing these issues. Irrespective of the reasons, if Abbott could not meet an existing contractual commitment to supply kits to France until mid-July 1985, it is most unlikely that there would have been stock available for supply to the UK for general use (as distinct from limited use in test evaluation and research) before that time and likely that there would have been some further delay before adequate supplies could have been made available for routine screening across the UK.

## **Testing in the United Kingdom: background**

### *The pressure to introduce testing in the UK*

**30.34** In the USA, the comments on and after 23 April 1984 of Margaret Heckler made it clear that screening tests, expected to be widely available within six months, would be

<sup>41</sup> Ibid [PEN.017.0568] at 0594. (See also: Professor Weiss – Day 48, page 168.)

<sup>42</sup> Ibid [PEN.017.1057] at 1059

<sup>43</sup> Ibid [PEN.017.1057] at 1061

<sup>44</sup> Dr McClelland – Day 50, page 79

<sup>45</sup> Memorandum dated 11 March 1985 'Introduction of Test to AIDS Related Antibody' [DHF.002.5475] at 5476. Although this is redacted, it is evident from the reference to the 'first US firm to have been given FDA approval' that it refers to Abbott.

applied generally.<sup>46</sup> The prediction proved inaccurate but, in the spring and summer of 1984, UK blood transfusion experts were aware that testing donated blood for the AIDS virus would be introduced generally in the USA. One of the major issues anticipated was that considerable pressure would then be put on the UK Transfusion Services to introduce an HIV test in the UK as in the USA.

**30.35** Although there was relief that the virus had been identified and that tests were being developed, there was also anxiety about the practical problems which testing would involve. In particular, as noted above, there was concern about false positive and false negative results and about how to counsel donors whose blood had tested positive.<sup>47</sup>

**30.36** Against this background, there was a powerful body of opinion in the UK, especially among the scientific community and transfusion practitioners, that all kits, whether produced in the USA or in the UK, should be evaluated locally before being recommended for use by Regional Transfusion Centres. The contrary opinion was expressed by some haemophilia clinicians who were concerned about delay, especially after the FDA had licensed kits for domestic use in the USA.

### *The UK regulatory framework*

**30.37** As noted in paragraph 30.2, the topic discussed in this chapter questioned ‘the decision not to use kits from the USA for testing donated blood for the virus as soon as they became available but, instead, to follow a process of evaluation of the kits before any such use’. Apart from the problem of lack of supplies for export discussed above, ‘availability’ of kits imported from the United States may require definition. Unlike the USA, where kits had to be approved and licensed by the FDA before they could be used for screening, UK authorities had no powers, under the Medicines Act 1968 or otherwise, to regulate the sale of kits imported into this country.<sup>48</sup> The FDA might grant an export licence before approval of a kit for domestic, US, use.<sup>49</sup> Kits might therefore be ‘available’ in the UK despite having no regulatory approval for domestic use in their country of origin.

**30.38** The Department of Health and Social Security (DHSS) responded promptly to the announcement of Abbott’s US licence, congratulating the company three days later in a letter dated 5 March 1985.<sup>50</sup> The letter gave a clear indication of the regulatory context and, notwithstanding the lack of statutory control over the importation and use of test kits, the expectations of the Department regarding the assessment of available test kits before their introduction to the UK:

You will know that we have no legal powers to prevent the sale of these products in the UK. However, an evaluation is needed because we know that would-be purchasers in the NHS will be looking to the Department for objective information which will help them in decision making. Of necessity, it will take a little time to get underway and we appreciate that you will wish to start selling now. In the absence of an evaluation report from the Department, we should be grateful if you would provide inquirers with as much information as you can in response to their questions about performance.<sup>51</sup>

<sup>46</sup> See narrative of events given at the commencement of proceedings on Day 48, pages 6–8. The press conference is also described by Douglas Starr in *Blood* [LIT.001.2936] at 2968.

<sup>47</sup> The atmosphere of the time was described by Dr McClelland – Day 50, pages 7–10

<sup>48</sup> A point made to Abbott in a letter to the company dated 5 March 1985 [DHF.002.6938]

<sup>49</sup> See Chapter 31, *The Introduction of Screening for Hepatitis C Antibodies in the Blood Donor Population in Scotland*, paragraphs 31.169–31.170. Ortho had an export permit for their Hepatitis C ELISA before the test was licensed for routine use within the USA.

<sup>50</sup> DHSS Letter [DHF.002.6938]

<sup>51</sup> *Ibid* [DHF.002.6938]

**30.39** From the outset, it was left to Abbott to decide whether to provide their own performance claims and supporting data and enter the market immediately. The Department's intention, as intimated in the letter, was to devise an evaluation protocol, on which all companies in the field would be given an opportunity to comment. Data in support of performance claims would be required and Abbott were invited to submit data confidentially for early review. Internally, a draft test protocol was prepared on 8 March 1985.<sup>52</sup> The Virus Reference Laboratory, CPHL Colindale, was to be involved in the evaluation and detailed requirements were drafted.

**30.40** As matters had developed in 1984 and early 1985, there were problems with the American ELISAs, including Abbott's kit, other than adequacy of supplies. As noted above, once testing began in the USA, serious problems with false positive results were evident.

### *The evaluation programme debate*

**30.41** As discussed in Chapter 18, *Collection of Blood – General*, the voluntary principle embedded in blood collection, in the UK generally and in Scotland in particular, imposed on the public sector transfusion services obligations of care towards donors, for their safety and general well-being in the course of the management of donation procedures.

**30.42** Regional Transfusion Directors (RTDs) in the UK considered that local evaluation was necessary. In Scotland, the emphasis remained on the use of commercial kits. On 12 February 1985, Professor Cash, National Medical Director of the SNBTS, wrote to Dr John Reid, Chief Medical Officer (CMO) at the Scottish Home and Health Department (SHHD).<sup>53</sup> He set out his concern about the rate of false positive results anticipated with the use of commercial kits and highlighted a number of factors supporting the need for a national kit evaluation programme. On 21 February 1985, Professor Cash and others from the SNBTS and National Blood Transfusion Service (NBTS) sent a letter to *The Lancet*, published on 2 March substantially repeating these views. The letter stated:

We believe that current commercial kits for HTLV-III antibody tests are likely to give a high rate of false-positive results. We would therefore recommend that careful consideration be given before they are introduced for the screening of all voluntary blood donors, for the amount and degree of unnecessary stress and hardship that a fair number of our donors and their families would thus have to undergo is unacceptable. This in turn could lead to a sizeable drop in the supply of blood and blood products. Of no less importance, for the safety of transfused patients, is the need to ensure that the first priority for the introduction of any HTLV-III antibody tests into a community is given to patients attending special (venereal disease) clinics and other members of the general public who wish to have access to these tests. If this is not done, many high-risk people, from a blood transfusion point of view, may present themselves at blood-donation sessions simply to find out their HTLV-III antibody status.

We do support, strongly, the screening of all blood donors for HTLV-III antibody testing, but we would advise that this is delayed until test systems have been appropriately evaluated and efforts have been made to give all members of the public access to HTLV-III antibody testing.<sup>54</sup>

<sup>52</sup> Draft test protocol [DHF.002.6939]

<sup>53</sup> Professor Cash's letter [SNB.013.2233]

<sup>54</sup> Ala et al, 'HTLV-III antibody screening of blood bank donors', *The Lancet*, 2 March 1985, page 524 [LIT.001.0374] at 0375. Consideration of 'alternative testing sites', for non-blood donors who might wish to be tested for HIV, are discussed below at paragraphs 30.156–30.161.

**30.43** The letter was signed by 11 NBTS Directors and seven Directors from Scotland, the five SNBTS Directors, Professor Cash as National Medical Director and Dr Robert Perry, Director of the Protein Fractionation Centre (PFC, the manufacturer of NHS blood products in Scotland). The emphasis on the interests of donors and their families highlighted the policy differences between the USA and the UK. The US policy of subordinating the 'psychic costs' of false positives to donors was not acceptable in the NHS environment.

**30.44** The letter was published on 2 March 1985. A different point of view was expressed in the same edition by Dr James Carlson and others of California, who advocated using a test with high sensitivity followed by confirmatory testing.<sup>55</sup> They concluded that, with proper procedures, the use of the most sensitive ELISA would not result in a major disruption in the procurement of blood or in the significant loss of future blood donors. However, the view of the UK transfusion specialists was strongly expressed and it is unlikely that a US view would have prevailed given the differing policy background circumstances.

**30.45** The need for local evaluation was acknowledged by others. For example, a widely attended international conference on AIDS, sponsored by the US Department for Health and Human Services and the World Health Organization (WHO), was held in Atlanta, Georgia (USA), from 15–17 April 1985. The conclusions and recommendations for member states included:

- Each country should assess the risk that AIDS poses to its population and establish methods of diagnosis through surveillance and laboratory testing, including specific tests for LAV/HTLV-III.
- Where feasible, potential donors of blood and plasma should be screened for antibody to LAV/HTLV-III....<sup>56</sup>

**30.46** In addition to the need to evaluate the tests' effectiveness in local populations, it was necessary, as with any new test system, to develop the practical, technological and procedural aspects of the introduction of HIV tests in Scottish laboratories, and laboratories elsewhere in the UK, to ensure that the kits adopted could be used rapidly and reliably for diagnostic and for screening purposes. A DHSS draft protocol of 8 March 1985 anticipated an evaluation report on each product submitted which would cover, among other practical issues, the compatibility of the assay with the needs of diagnostic, blood transfusion and research laboratories.<sup>57</sup>

**30.47** Any evaluation exercise had to be carried out on the actual assays proposed for introduction. As will appear later, there were significant differences in experience between different versions of fully developed commercial products marketed for general use. Starting some time after March 1985, when the US kits became available for research purposes, a UK evaluation would have taken some months. It was, however, a necessary step: Professor Tedder spoke of the general experience of assays, in transfusion and diagnostic settings, which had not been tried on the target population, giving rise to devastatingly high levels of false positivity. His view, which is accepted, was that:

You conduct a field trial to make sure that assays are giving you useful and as accurate as possible results and, of course, without having your repeat reactive

<sup>55</sup> Carlson et al, 'HTLV-III antibody screening of blood bank donors', *The Lancet*, 2 March 1985, [LIT.001.0374] at 0374–75

<sup>56</sup> Acquired Immune Deficiency Syndrome (AIDS) – WHO Consultation [DHF.001.7253] at 7253–54

panel from your donors, you do not know what form of confirmatory testing you need. So, until you have got the substrate for your confirmatory testing, which is your repeat reactive donors, you can't define what's going to be the best algorithm or the best protocol for confirmation. You really don't want to be screening donors and developing a large panel of repeat reactors without knowing how to deal with them. That would be very damaging to transfusion practice.<sup>58</sup>

### ***Development of a United Kingdom HIV test***

**30.48** The background to the development of scientific tests for HIV infection in the UK is described in Chapter 29, *The Discovery of HIV and the Development of Screening Tests*. In short, Professor Tedder and Professor Robin Weiss,<sup>59</sup> following rebuff by the DHSS<sup>60</sup> initiated research and developed an effective serological assay on a commercial basis on behalf of their institutes, the Chester Beatty Cancer Research Institute and the Middlesex Hospital, and in due course established unchallenged right to the intellectual property developed. As matters transpired, all of the test kits that became relevant to progress towards screening had one thing in common: research institutes, pharmaceutical companies and individuals had intellectual property rights in the science underlying the tests. In the USA, Dr Gallo's know-how was licensed to pharmaceutical companies for development.

**30.49** The work of Professors Weiss and Tedder was known, in general terms, to the UK government but, throughout the development stages and, in particular, until 4 July 1984, when the prototype assay was ready for laboratory application, it was funded by their institutions.<sup>61</sup> As commented in Chapter 29, *The Discovery of HIV and the Development of Screening Tests*, paragraph 29.42, it would have been highly unlikely that Professor Weiss and Professor Tedder would have disclosed details before publication of the patent specification: until that stage, the validity of the patent could have been undermined.

**30.50** Professor Tedder sought UK government funding for the scale-up of the Middlesex Hospital/Chester Beatty Cancer Research Institute test (MH/CB test) for industrial production in a letter to Dr Alison Smithies, DoH, dated 18 December 1984.<sup>62</sup> At the end of the year and early in 1985, Dr Smithies prepared draft submissions to Ministers supporting the application and seeking approval for the introduction of the screening test.<sup>63</sup> Her advocacy in support of the project marked the beginning of a new phase in the progress towards routine screening for anti-HIV in the UK as a whole. As she presented the project, it was 'a product of the co-operation of British Science and British Industry', implicitly acknowledging the non-governmental character of the test.<sup>64</sup>

**30.51** In following the history of events in 1984 and 1985 relating to the development of a UK test for HIV below, it has to be borne in mind that institutions which had sought intellectual property rights, in common with all manufacturers of test kits, had interests which depended in part on maintaining the confidentiality of their work.

<sup>58</sup> Professor Tedder – Day 49, page 77

<sup>59</sup> Currently Emeritus Professor of Viral Oncology at UCL Medical School, London.

## The progress of introducing a test to the United Kingdom

### *Establishment of expert groups*

**30.52** At a meeting of the UK Central Blood Laboratories Authority (CBLA) Central Committee for Research and Development in Blood Transfusion in June 1983, a Working Group on AIDS in relation to Blood Transfusion was set up and first met on 14 October 1983.<sup>65</sup> By that stage, the Medical Research Council (MRC) had set up a similar committee which had its initial meeting on 10 October 1983.<sup>66</sup> The MRC committee noted that, while the laboratory markers for AIDS were well established, their relevance in screening and in a possible 'precursor state' was not. As reported, screening was not among the topics discussed in detail by the working group on 14 October. Although it appears that there was nothing of importance to note at that point specifically relating to the development of serological assays for HIV identification other than uncertainty, the interest of two important UK advisory bodies had been engaged.

**30.53** In Scotland, a special meeting of the Co-ordinating Group of the SNBTS took place on 7 February 1984.<sup>67</sup> It was agreed that Professor John Cash, Medical Director of the SNBTS, should write to Dr Harold Gunson, Director of the Manchester RTC and Chairman of the Regional Directors of the National Blood Transfusion Service for England and Wales (NBTS), recommending that there should be a single UK Working Group on AIDS with Scottish representation. Instead of writing to Dr Gunson directly, Professor Cash wrote to Dr Albert Bell, SHHD, reporting the recommendation on 15 February 1984 and suggesting that the group should be responsible to the health departments (DoH and SHHD) for coordinating research covering the interface between blood transfusion and AIDS.<sup>68</sup> He included in the major areas requiring attention a prospective clinical study to determine the value of existing AIDS tests.

**30.54** Professor Cash's hopes of a UK-wide advisory group, including Scottish representatives with the wide remit he proposed and a direct relationship with the health departments, were not realised. Professor Cash would later write, on 24 January 1985, that he did not know whether the SNBTS Directors' views, communicated to Dr Bell on 15 February 1984, had been transmitted to the DHSS.<sup>69</sup> It appears from his letter that he, and other officials in the transfusion service in Scotland, were frustrated by the arrangements made in England. Professor Cash complained that they were left 'completely in the dark' about developments.

**30.55** Professor Cash's protestation was not wholly justified. Dr Gunson met with Dr David Tyrrell, Chairman of the MRC Committee on AIDS, Professor Tedder and two NBTS Directors, Dr Tim Wallington and Dr Marcella Contreras, on 28 June 1984 to discuss issues surrounding the introduction of tests. Dr Wallington was Consultant Clinical Immunologist at NHS Blood and Transplant and the North Bristol NHS Trust. Dr Contreras was Director at the Regional Transfusion Centre at Edgware, London, and that centre was believed to be most likely to show early evidence of the virus entering the donor population.<sup>70</sup> Dr Brian McClelland, Director of the Edinburgh BTS, had been invited but was prevented from attending the meeting by travel problems.<sup>71</sup>

<sup>65</sup> Minutes of CBLA meeting [DHF.002.4834]

<sup>69</sup> Professor Cash's letter [SNB.005.7304]

<sup>70</sup> Dr McClelland – Day 50, pages 2–3

<sup>71</sup> *Ibid* pages 2 and 7

**30.56** Dr Gunson sent a letter, dated 3 July 1984 and copied to Dr McClelland among others, recording the discussions which had taken place at the meeting on 28 June.<sup>72</sup> He narrated that Dr Tyrrell had taken the initiative by proposing that the MRC could help in setting up a research project on blood donors using the detection of anti-HTLV-III as a possible marker of donors at high risk of transmitting infection. The development of a viable test for anti-HTLV-III by Professors Weiss and Tedder was identified as promising. The stages in the evaluation project then envisaged included testing at the Middlesex Hospital, North West Thames RTC and Bristol and Manchester RTCs. Dr McClelland thought that, if he had attended the meeting, he would have suggested that it would have been useful for the evaluation to be extended to include a Scottish centre: the West of Scotland centre was very experienced in evaluation and it would have been a valuable learning experience to get in 'at the ground floor'.<sup>73</sup> That did not happen, however.

**30.57** Dr Gunson's letter stated:

[We] all agreed that at the present time this test should be regarded as a research project and that it should not be introduced as a routine screening test on blood donations without proper appraisal. It is important, however, that a study should be started as soon as possible so that it would be possible from a practical point of view to answer questions on the use of the test in the U.K.<sup>74</sup>

**30.58** Dr McClelland sent a copy of the letter to Professor Cash on 7 August 1984. In the covering note, he wrote:

I will be keeping in touch with Richard Tedder about the development of assay reagents and I feel this is something we should discuss in the near future.

....

I imagine there is likely to be a breathing space of many months before a test is available and relevant trials come forward to put us under pressure to introduce screening. Nevertheless ... it would seem very important indeed that we do whatever is necessary to retain participation in this development.<sup>75</sup>

**30.59** It appears unlikely that Dr McClelland was fully informed of developments at this stage. The first results of research using the MH/CB assay developed by Professor Weiss and Professor Tedder were published in an article by Dr Rachanee Cheingsong-Popov and others on 1 September 1984.<sup>76</sup>

### *The practicalities of introducing screening*

**30.60** In the autumn of 1984, the emphasis turned to the practical implementation of screening. A working group was proposed by the DHSS to provide guidance about the consequences for the NBTS of the introduction of a screening test for HIV.<sup>77</sup> The initial list of proposed members did not include any from Scotland but, as a result of the intervention of the SHHD, Dr McClelland was allowed to join the group.<sup>78</sup>

<sup>73</sup> Dr McClelland – Day 50, pages 6–7

<sup>74</sup> Dr Gunson's letter [SNB.006.5978]

<sup>75</sup> Covering note [SNB.006.5977]

<sup>76</sup> Cheingsong-Popov et al, 'Prevalence of antibody to human T-Lymphotropic virus type III in AIDS and AIDS-risk patients in Britain', *The Lancet*, 1 September 1984 [LIT.001.0417]

<sup>77</sup> Memorandum dated 13 August 1984 [DHF.002.5897]

<sup>78</sup> Letter dated 26 September 1984 [SGF.001.0929]

**30.61** The working group held its first meeting on 27 November 1984.<sup>79</sup> Although the DHSS view was that the meeting had gone reasonably well,<sup>80</sup> Dr McClelland reported back to his fellow Directors in Scotland on 11 December 1984 that he had found the outcome of the meeting ‘disappointing’.<sup>81</sup> He recorded, however, that it had been agreed to test all donors once an antibody test for HIV was available. The minute of the Regional Directors’ meeting on 23 January 1985 described the November meeting as ‘unproductive’.<sup>82</sup> Professor Cash’s reaction to the report in his letter to Dr Bell of 24 January 1985, describing the meeting as ‘wholly inadequate’ and ‘a waste of public money’,<sup>83</sup> was perhaps extreme but may reflect a view still held by some Scottish transfusion experts that they were not fully engaged with developments in England.

**30.62** There was an attempt to engage directly with Professor Tedder’s team. On 20 December 1984, Dr Robert Crawford of the West of Scotland BTS visited Professor Tedder at the Middlesex Hospital, apparently to obtain information about the tests being developed and, possibly, to assess whether there might be potential for the development of tests in Scotland.<sup>84</sup> Dr Crawford reported that he had been told of the Weiss/Tedder test in radioimmunoassay (RIA) format (though, as discussed below, that had already been superseded by work on an ELISA format) and had a description of the US tests. He knew of the different cell lines employed to propagate the virus antigens. He told Professor Tedder that, given the cells and virus and his support, Scotland might ‘go it alone’ and discussed the capacity of Glasgow to do the work. Dr Mitchell explained that the West of Scotland had 100,000 specimens that could be tested and could help the development programme.<sup>85</sup> By this stage West of Scotland BTS staff were experienced in investigating the Hepatitis B virus.<sup>86</sup> The proposal did not find support, however. Dr Mitchell thought (probably correctly, even at this late stage) that there were difficulties in sharing information. As commented already, the MH/CB assay was a proprietary test. Wellcome Diagnostics had entered into a commercial contract for development of the MH/CB test. It appears that there was no reasonable prospect of scientists in Scotland becoming involved in the English programme.

**30.63** The development of the English evaluation programme to the end of 1984 had not involved the Scottish scientific service to any material extent. Work carried out in Scotland included collaboration with French and US colleagues and that continued into 1985. Encouraged by Professor Cash, Dr Perry wrote to Dr Luc Montagnier on 8 February 1985, discussing a number of projects and, in particular, attempted to obtain supplies of LAV (that is, HIV) test kits from the Institut Pasteur, in order that these kits could also feature in a Scottish evaluation.<sup>87</sup> Professor Cash said that the initiative with the Institut Pasteur failed after ‘the lawyers moved in’.<sup>88</sup> It appears, however, that scientists working in Scotland would not have been able to carry out an independent virological evaluation of

the kits available: what they were engaged in was a practical assessment of the mechanics of introducing US test kits.<sup>89</sup>

## Scottish concerns at lack of progress

### *A perceived lack of effective coordination*

**30.64** Professor Cash's frustration at a perceived lack of progress is reflected in documents recovered by the Inquiry: he was clearly concerned about what he saw as the lack of effective coordination of the UK approach to transfusion and AIDS. In his letter to Dr Bell dated 24 January 1985, he said:

[I]t is with dismay that I must conclude that there are just no mechanisms in the UK for these crucially important topics to be discussed, openly and confidentially, and for clear, co-ordinated policies to emerge. The biggest anxiety of the NBTS Directors with regard to this problem is the Scots: that they will unilaterally move to come in line with the American proposals. They're right: we are in detailed discussion with commercial (kit) companies, our technical staff are already looking at ways of introducing the technology within existing staff establishments, we have the Western Blot technique (HQ and SE labs). We are already liaising with local (Communicable Disease) physicians with a view to securing care for our positive donors and we are currently arranging our financial planning accordingly. I advised the NBTS Directors that we would do everything possible to avoid such a development. They were not impressed ... I had much sympathy with them ....<sup>90</sup>

**30.65** The threat in Professor Cash's letter, that the SNBTS would proceed unilaterally to introduce US test technology, had some basis. At the time, commercial companies were approaching Regional Transfusion Directors (RTDs) in Scotland with ELISA tests. In his witness statement, Professor Cash said that the SNBTS had evidence that the FDA was by then well-advanced in its assessment of HIV donation screening kits, which was later published.<sup>91</sup> As far as the SNBTS could judge, there was no evidence that their pleas for interdepartmental collaboration were succeeding.<sup>92</sup>

**30.66** Professor Cash said, with reference to the national blood transfusion services generally:

We, the people responsible, were not in control of actually, urgently getting together, looking at these tests, to actually determine: is it 1 per cent or 0.5 per cent or 10 per cent? What are we dealing with here? For me, as a manager, it's a madness when the whole thing is drifting away here, and there are very serious matters that, in my view, were not being properly addressed.<sup>93</sup>

**30.67** Professor Cash was not alone in expressing concern about progress. Dr McClelland was also concerned, though the focus for his frustration was different. On 8 January 1985, he wrote to Wellcome on behalf of the RTDs in Scotland expressing continuing concern about the lack of a screening test for blood donations:

<sup>89</sup> On 25 November 1985, Dr Perry wrote to Professor Weiss [SNB.007.5427]. He noted that progress on earlier proposals had been interrupted by Health and Safety problems. The PFC had not been technically equipped to handle live virus.

<sup>90</sup> Letter [SNB.005.7304]

<sup>91</sup> Witness Statement [PEN.017.1038] at 1040; Patricciani et al, 'An analysis of serum samples positive for HTLV-III antibodies', *New England Journal of Medicine*, 4 July 1985 [PEN.017.0651]

<sup>92</sup> Witness Statement [PEN.017.1038] at 1040

<sup>93</sup> Professor Cash – Day 48, page 43

I am not reassured by the information available to me at present.

....

I am concerned at the apparent lack of progress and I sincerely hope that you can reassure me that Wellcome will shortly be in a position to make some form of antibody detection system available. I feel certain that I am speaking not only for my Scottish colleagues but for other Regional Transfusion Directors in the UK if I say that it would be a tremendous step forward if even a limited supply of materials for HTLVIII antibody testing were to be made available in the near future ....

I really cannot over emphasise the urgency of this situation. I am sure that from the recent press coverage, you can be under no doubt of the extreme pressure being placed on the transfusion services to ensure that no 'high risk donors' donate blood – a task which is essentially quite impossible unless some form of screening test is available.<sup>94</sup>

**30.68** He was looking for a positive proposal from Wellcome. He explained the background to his letter in evidence to the Inquiry – he was frustrated that 'we weren't getting on with it'.<sup>95</sup> Wellcome did not respond. Dr McClelland thought they were 'up to their ears in trying to make the test'.<sup>96</sup>

**30.69** Against this background, Professor Cash took steps to progress matters, at least insofar as Scotland was concerned. He was keen that a Scottish centre should be involved in any evaluation exercise and attempted to promote such an exercise involving the west of Scotland centre.<sup>97</sup>

**30.70** Professor Cash's frustration is clear, particularly because he and his Scottish colleagues were not more closely involved. It is less clear what Scotland could have done alone, however. If Scotland had followed an individual path at this time there would still have been a need for a prior assessment of local data on the specificity of each proposed test.<sup>98</sup> That would have required the growth and propagation of HTLV-III. While that could be done at CAMR Porton,<sup>99</sup> Dr McClelland thought it highly unlikely that there was a facility in Scotland that could undertake the virology involved.<sup>100</sup> The containment facilities required to handle live virus were not available.

### *The proposal to commence test kit assessment in Scotland*

**30.71** On 21 January 1985, Dr Mitchell wrote to Professor Cash, advising that Abbott had visited 'with a view to starting some evaluation of the Abbott ELISA test system'.<sup>101</sup> Abbott were frequent visitors to check on Glasgow's progress with the testing of other products.<sup>102</sup> Professor Cash was also visited by Abbott.<sup>103</sup> Dr Mitchell noted that some

<sup>102</sup> Dr Mitchell – Day 51, page 16

<sup>103</sup> Day 48, page 74

problems had arisen from FDA requirements for blind testing and ethics review board approval.<sup>104</sup> He thought that these problems could be overcome and he had been asked to write a letter to Abbott setting out the position in terms advised by the company.

**30.72** In a minute to Mr Alexander Murray, SHHD, coincidentally also dated 21 January 1985, Dr Bell said that '[t]he RTC at Law [Hospital, Glasgow] is testing the Abbott (USA) screening test'.<sup>105</sup> In the light of Dr Mitchell's letter to Professor Cash, Dr Bell's understanding that testing was already in hand was incorrect: it was about March or April 1985 that an Abbott HIV test kit was first available for initial evaluation, at Ruchill Hospital.<sup>106</sup> However, the SHHD understood the intentions of the SNBTS at the time. It appears that Professor Cash, Dr Ewa Brookes (Director of the Dundee RTC), Dr William Whitrow (Director of the Inverness RTC), Dr McClelland and Dr Mitchell had discussed the issue when they were at Trinity Park House in Edinburgh in the week beginning 14 January 1985.<sup>107</sup> According to Professor Cash, the outcome of those discussions was a decision that the Scottish Directors had to take action themselves.<sup>108</sup>

**30.73** Meanwhile, and in response to Dr Mitchell's letter, Professor Cash developed his proposals:

1. That the [West of Scotland BTS] should undertake, on behalf of the SNBTS, initial evaluation studies of commercial HTLV-III antibody kits, but that the current pressure from commercial organizations to meet their deadlines should be resisted and priority given to SNBTS interests – particularly in terms of confidentiality and ethical clearance.
2. That retrospective studies (on donor samples) currently in store should be used provided:
  - (a) Steps are taken to ensure that no one can identify the donors.
  - (b) That the selection of donor samples is representative and random (not exclusively high risk donors and does not deliberately exclude high risk donors by virtue of previous tests).
  - (c) That the donors associated with factor VIII batch 023110090<sup>109</sup> are not used for these evaluation studies.
  - (d) That the donor samples would come exclusively from the WBTS donor panel.
3. That initial donor samples should be of sufficient volume to enable the following:
  - (i) Initial test
  - (ii) Repeat test if necessary
  - (iii) Reference test (? Western Blot) if necessary
  - (iv) As many residual 1 ml aliquots (at least 2) so that the same samples can be tested with other emerging kits and the results compared.<sup>110</sup>

<sup>109</sup> That is, the 'implicated batch' thought to be responsible for the infection of 'The Edinburgh Cohort' of haemophilia patients with HIV in 1984. See Chapter 10, *Knowledge of the Geographical Spread and Prevalence of HIV/AIDS 2*.

<sup>110</sup> Professor Cash's letter to Dr Mitchell [SNB.005.9713]

**30.74** He also discussed ethics approval and offered his assistance to secure that if necessary. He reported that the manufacturers had readily agreed to supply the kits necessary for evaluation free of charge.<sup>111</sup> He copied his letter to all the RTDs in Scotland and also to Dr Bell at the SHHD. At that stage, there were no commercial tests available for donor exclusion purposes but it was envisaged that initial evaluation studies would not be restricted to Abbott.<sup>112</sup>

**30.75** In his oral evidence, Dr Mitchell thought that the proposal would not have been practicable. He said:

I think the difficulty would have been to pursue this idea would be – firstly, the availability of samples, availability of commercial tests. I think there would be a difficulty in any manufacturer at that level, at this time, supplying sufficient tests for us to have a look at and – I think they were busy as it were, in their own backyard, trying to develop the tests. I think what Abbott might have been saying was, ‘In the event that we were willing to do this, we would ask you to do the following things’, or insist on the following things.

I always said to all companies that ever approached us about any test, ‘We will look at your test, we will analyse it, quite unknown to you, we will look at the results, we will publish the results, fear or favour.’ We believe in telling what exactly we find. We will not be stampeded into making allowances for this, making allowances for that. We had to be sure that the test was fit for purpose. That was for mass screening, day in, day out. Same test today, same test tomorrow, the same expected results, the same expected performance.

....

I think the reason that we couldn’t pursue this was just because the materials were not available, weren’t readily available.<sup>113</sup>

**30.76** As he saw it, 1000 kits might have enabled an exercise that was worth doing but he did not think that a manufacturer would have been prepared to supply such a number of kits.<sup>114</sup> Further, he did not think that access would have been allowed to the MH/CB material necessary for evaluation of that assay.<sup>115</sup>

### ***SHHD opposition to the SNBTS undertaking its own kit evaluation***

**30.77** The proposal was not put to the test, however. Professor Cash advised the Inquiry that, some days after this letter was sent, he was invited to discuss the situation with Dr McIntyre who ‘made it clear that SHHD was strongly opposed to the prospect of SNBTS undertaking its own kit evaluation’.<sup>116</sup> Dr McIntyre also advised Professor Cash that the SHHD had assured the DHSS that they were content with the evaluation of the kits being managed by the DHSS and that ‘the commencement of routine HIV donation testing in Scotland would be determined by Ministers, on the advice of DHSS and that this date would apply across the UK’.<sup>117</sup> On that approach, the question was answered conclusively

<sup>117</sup> Ibid [PEN.017.1038] at 1040

by policy decisions made by the SHHD, which Professor Cash described as 'hostile' to the initiative.

**30.78** Dr Mitchell and his colleagues were disappointed at being excluded from the overall UK process: it hurt their sense of pride.<sup>118</sup> While he was less than certain, the general tenor of Dr Mitchell's recollection was that the proposal did not proceed because there had by this time been agreement between the DHSS and the SNBTS that the Tedder/Weiss process should have priority.<sup>119</sup> Professor Cash's approach was different: he was not willing to accept that the SHHD and the DHSS might have a legitimate interest in avoiding duplication of costs. He thought that responsibility lay with the SNBTS and that they should have been allowed their investigation.<sup>120</sup>

**30.79** From the sequence of events, it appears that decisions taken by the Expert Advisory Group on AIDS (EAGA, a non-departmental body established to provide the UK Health Departments with Expert advice on AIDS) contributed to the discontinuation of the Scottish initiative.<sup>121</sup>

**30.80** Professor Cash maintained that the SNBTS initiative had to be stood down 'in view of the hostile reaction of SHHD'.<sup>122</sup> The Inquiry sought comments from Dr McIntyre on this account of events and his response came in an e-mail from the Scottish Government.<sup>123</sup> Dr McIntyre took issue with the proposition that he ever spoke to Professor Cash in a hostile manner. He commented that 'SHHD treated Dr Cash and his colleagues in a professional manner and did all they could to help as this was a major health problem'.<sup>124</sup>

**30.81** Professor Cash thought that he had discussed the matter with Dr Mitchell and Dr McClelland. In a further attempt to shed light on this episode, both Dr McClelland and Dr Mitchell were asked for their recollections. Dr McClelland had 'no recollection of this whatsoever'.<sup>125</sup> Dr Mitchell had no recollection of actual discussions on the subject in 1985, although he could remember it being said that the SNBTS were not going to do the evaluations.<sup>126</sup> Professor Cash's account of the Department's 'hostility' to an SNBTS *initiative* was not disputed, including by Dr McIntyre, however, and it is appropriate to conclude that the SHHD did indeed express strong opposition to an independent Scottish evaluation.

**30.82** The question of an independent Scottish evaluation was effectively settled at this point by the EAGA. The EAGA was set up around the turn of 1984–85<sup>127</sup> with the purpose of providing 'advice on such matters relating to HIV/AIDS as may be referred to it by the Chief Medical Officers of the Health Departments of the United Kingdom' and first met on 29 January 1985.<sup>128</sup> The membership of the group was announced in the House of Commons on 20 February 1985.<sup>129</sup> The Group had a wide range of specialist interests: Genito-Urinary; Blood Transfusion; Epidemiology; Physicians and Nurses; Virology;

<sup>128</sup> Minutes of meeting [SNB.001.0002]

<sup>129</sup> Extract from *Hansard* [SNF.001.3323]

Immunology; and Microbiology were all represented.<sup>130</sup> Professor Cash and Dr McClelland both attended the first meeting.

**30.83** At that meeting it was agreed that a screening test for all UK blood donors should be made available as soon as practicable and a sub-group on implementation was set up to consider screening tests for AIDS and, in particular, the best way of introducing the service when the tests became available.<sup>131</sup> The sub-group comprised Dr Gunson, Dr McClelland, Dr Philip Mortimer (Consultant Virologist), Dr Tony Pinching and Dr Philip Rodin (GUM specialists) and Professor Tedder, under Dr Smithies as Chair. It was not the specialist UK advisory group envisaged by Professor Cash, although Scottish interests were now fully represented at the national level. At a meeting of the SNBTS Co-ordinating Group held on 19 February 1985, the evaluation programme (monitored by an EAGA sub-group) was noted and it was agreed, after full discussion, that the proposals for a west of Scotland study should not be pursued at that time.<sup>132</sup> Professor Cash reported to Dr Bell that the SNBTS directors had agreed to hold off from validation of kits until protocols had been agreed through EAGA.<sup>133</sup> Dr Bell welcomed the news on 6 March.

**30.84** The decision to await the completion of the tests arranged by EAGA was reinforced on 20 June 1985, when the SNBTS Directors again considered the introduction of testing for HIV.<sup>134</sup> It was noted that the SHHD had undertaken to provide funds for testing kits once it had been agreed to commence routinely.<sup>135</sup> On 27 June 1985, Professor Cash wrote to Mr Davies, SHHD, giving advance notice of a need for additional resources for screening.<sup>136</sup>

**30.85** In his evidence to the Inquiry, Professor Cash commented that it was his view that, if the SNBTS had been allowed to 'go it alone', testing of donated blood for HIV in Scotland with commercial kits could have been introduced around the same time as such screening commenced in the Netherlands and Australia.<sup>137</sup> In round terms, that would have involved a saving of about four months.

**30.86** Dr Scott was asked to comment on Professor Cash's position but, apart from noting generally that Professor Cash's views were not always entirely favourable to the SHHD, felt he could not comment on the impression Professor Cash gave, that the SHHD were holding him back.<sup>138</sup> He deferred to Dr McIntyre on the sequence of events that led to the abandonment of the proposal for a Scottish evaluation but Dr McIntyre was not able to assist.<sup>139</sup>

**30.87** It should be borne in mind that the first meaningful supplies of Abbott kits for evaluation did not arrive in Glasgow until April and scientists in the West of Scotland BTS did not have access to the MH/CB assay. There was, on the balance of evidence, no real prospect of Scotland being able to introduce screening four months before 14 October 1985.

<sup>130</sup> The members and representatives of government departments are listed in the notes of the first meeting [SNB.001.0002]

<sup>131</sup> Ibid [SNB.001.0002] at 0005. Dr Covell also prepared a note of the meeting [SGH.002.7296]

<sup>139</sup> Ibid pages 139–140

## Development of an HIV test in the United Kingdom

### *Choosing the test format: radioimmunoassay or enzyme-linked immunosorbent assay*

**30.88** The need to scale up testing from an assay working in the laboratory to kits which could be used for hundreds of thousands of tests in the blood transfusion services raised questions as to the nature of the test to be taken forward as well as to the selection of a manufacturer. The characteristics of the two test formats considered are discussed in Chapter 29, *The Discovery of HIV and the Development of Screening Tests*, at paragraph 29.27.<sup>140</sup> Professor Tedder's test was initially developed as a radioimmunoassay (RIA), in which radioactive isotopes are used in the detection of the target antibody.<sup>141</sup> Within the NBTS in England and Wales in 1984, there was a preference for RIA testing<sup>142</sup> and Professor Tedder's initial work reflected the reality of that preference. In his letter of 3 July 1984 to Dr Smithies, Dr Gunson expressed the view that '[i]t would be an advantage for the NBTS if [the new test] was in the format of the Blood Products Laboratory (BPL) RIA test for [the Hepatitis B surface antigen]'.<sup>143</sup> The BPL were familiar with RIA testing and that was an obvious attraction. On 23 January 1985, at the meeting of the RTDs in England, the position was still that '[t]he preference within the NBTS [was] for an RIA'.<sup>144</sup>

**30.89** Within the public service in England and Wales, it was also hoped that the CBLA might become involved in the preparation of the test kits.<sup>145</sup> At official level, there was interest in involving other public sector institutions in the development work, in particular CAMR Porton, who were thought to have the necessary equipment and expertise.<sup>146</sup>

**30.90** Initially, official support for the principle of a UK test reflected the BPL's preference. For example at the 16th meeting of the CBLA on 1 February 1985, the subject was discussed. The minutes record:

The Director [of BPL] advised that if given the antibody BPL could produce a test as an alternative to the Chester Beatty's work in association with industry, at a much lower cost. Dr Gunson confirmed the necessity for the test and referred to a Departmental working party considering the matter. It was noted that the CBLA role in this matter was not yet established but there would be a related capital requirement for equipment for RIA tests.<sup>147</sup>

**30.91** Throughout the industry, however, RIA technology was being superseded in routine testing because the radioisotopes employed in such assays were potentially dangerous.<sup>148</sup> It was increasingly recognised that radioactivity involved risk and, while the risk could be contained in the laboratory, it was considered undesirable to have a 'widespread proselytization' of RIAs into the community.<sup>149</sup> Once Professor Tedder and Professor Weiss had decided to work with the diagnostic industry it would have been difficult to resist

<sup>140</sup> See also: Professor Tedder – Day 49, pages 65–67

<sup>141</sup> Ibid pages 65–67

<sup>142</sup> The preference within the NBTS in England and Wales for RIA testing did not appear to be replicated in the SNBTS: Dr McClelland's Witness Statement [PEN.017.1337] at 1358

<sup>143</sup> Dr Gunson's letter to Dr Smithies [SNB.006.5978] at 5979

<sup>147</sup> Minutes of CBLA meeting [DHF.003.0219] at 0224

<sup>148</sup> Professor Cash – Day 48, page 136

<sup>149</sup> Professor Tedder – Day 49, page 66

the global move towards ELISAs and away from RIAs.<sup>150</sup> ELISA technology carried no biological hazard and Wellcome had scientists highly skilled in producing the enzyme ligands used in such assays.<sup>151</sup>

**30.92** Professor Tedder remembered attempts being made to involve the BPL and meetings being held with Dr Lane, the CBLA and the BPL. Eventually, however, it became necessary 'to let them down and say, "We don't want to do a radioimmunoassay, we are going to run with Wellcome"'.<sup>152</sup> Wellcome Diagnostics was engaged to carry out the research and development necessary to achieve the ELISA-based test kit and CAMR Porton were enlisted to help with the scaling up as sub-contractors to Wellcome.<sup>153</sup> Engagement with Wellcome led to the abandonment of Professor Tedder's RIA in favour of ELISA technology.

**30.93** Although in the end Wellcome was selected, the choice of a manufacturer for the MH/CB test was not straightforward. Professor Tedder told the Inquiry that he made contact with the five diagnostic companies licensed in the US to develop tests and a number of British companies. None of the US companies would work with the British scientists, although they were discarding large quantities of the antigen required for the British test.<sup>154</sup> Professor Tedder thought that the reason for rejection was twofold: (i) the terms of the contracts to which the US companies were party and (ii) scepticism about the effectiveness of the competitive assay which he and Professor Weiss had developed.<sup>155</sup> In order to work with companies outside the National Cancer Institute franchise it was necessary to have an independent UK-based isolate, such as the isolate he and Professor Weiss were developing. Wellcome were 'the most enthusiastic and the quickest off the mark'.<sup>156</sup>

**30.94** The question of scale-up of the test reagents, including quantities of the virus, had been moving forward since the previous summer, with implications for the type of test which would eventually be manufactured. As Professor Tedder commented, references in the DHSS minutes around this period to the development in the UK of an RIA for screening were inaccurate because, at that time, the test which he was developing with Wellcome was already an enzyme-based test, not an RIA, though that does not seem to have been understood by officials.<sup>157</sup> The research group had already begun work on the ELISA with Wellcome in October or November 1984.

**30.95** Failure to appreciate that there had been a decision to adopt the ELISA format appears to have continued. At the meeting of EAGA on 29 January 1985 Dr Gunson reported that BTS were in overwhelming favour of an RIA test on the view that it was more accurate than an ELISA test on which all the US tests were based and suited the equipment which they already had for Hepatitis B testing. Professor Arie Zuckerman (Professor of Microbiology, Royal Free Hospital School of Medicine, London) was in favour of the evaluation of the US test before an RIA test was adopted.<sup>158</sup> A note prepared by Dr Covell, SHHD, of the meeting of EAGA on 29 January 1985 reported that Professor Weiss

<sup>150</sup> Ibid pages 65–66

<sup>158</sup> Minutes of EAGA meeting on 29 January 1985 [SNB.001.0002] at 0005, paragraph 21

was negotiating with Wellcome Diagnostics to develop a test for BTS.<sup>159</sup> The note did not reflect an understanding that there had been a move to adopt an ELISA format. The assumption that the MH/CB test would have an RIA format appears to have continued.

**30.96** While it is necessary to be aware of this issue, having regard to the extensive references to it in the evidence already noted and noted later in historical context, in the end it did not impact on progress. In this, as in other areas, Professor Tedder and his industrial collaborators got on with the work necessary to develop their assay, adopting the test format thought best to suit market demand.

### *Progress with scale-up*

**30.97** As already noted, CAMR Porton were enlisted to help with the scaling-up as sub-contractors to Wellcome.<sup>160</sup> CAMR initially did not provide antigen appropriate for use in the assay, however, as they did not follow the exact protocol Professor Tedder and his colleagues had developed for engendering maximal antigen retention in the cell component. Professor Tedder acknowledged the difficulties CAMR had in scaling up for industrial production: the conditions of the culture they used encouraged antigen to come out of the cell into the supernatant, whereas it was necessary for the assay under development that the virus remained in the cells.<sup>161</sup> It was not until late spring 1985 that the CAMR antigen came on-line.<sup>162</sup> That did not affect the progress of research or cause delay, however, since enough high-quality antigen was produced by Professor Tedder's laboratory-scale equipment to enable the research programme to continue.<sup>163</sup> When it was decided that Wellcome should develop a test based on the MH/CB patent-protected competitive technique, Professor Tedder and Professor Weiss supplied their own British isolate.<sup>164</sup>

**30.98** Reports of work in hand at the first meeting of EAGA on 29 January 1985 indicate that research was continuing.<sup>165</sup> The availability of screening tests was discussed and Professor Weiss reported on the work with Wellcome Diagnostics. There were still problems to be solved.<sup>166</sup> There was still intent among the RTCs to proceed uniformly across the transfusion services, a point stressed at a meeting of the RTDs on 17 April 1985: their interest was in having 'uniformity of action'.<sup>167</sup>

**30.99** Dr Covell, SHHD, prepared a note of the meeting of 29 January 1985 that indicated that the choice of test systems was still open. He reported:

Prof Weiss said that he was negotiating with Wellcome Diagnostics to develop a test for BTS which would be as reliable as other tests and would detect serum antibodies specific to HTLV III. Negotiations were just beginning and he could not give a date when it would be available. It may turn out that overseas tests may be produced quicker and could be more reliable.

Prof Zuckerman said that three United States firms, Travenol, Dupont and ? [third firm not named in the text] have tests ready which he hopes to evaluate

within the next three months and to compare with Dr Tedder's test. He hoped they would not only be available for BTS, indeed even if there was a delay they should wait until others could also be supplied.

Dr Whitehead said there were technical difficulties in the scaling up of the test. He also mentioned the possibility of patent restrictions on the viral strain involved.<sup>168</sup>

**30.100** Dr Covell's note disclosed a significant move from the earlier concentration on the interests of the blood transfusion services in discussing the approach to the development and introduction of HIV assays. Professor Tedder commented that a test would have to be made available to all who wanted it, reflecting his understanding that many individuals attending genito-urinary medicine (GUM) clinics, haemophilia patients and those who encountered needle stick injuries in the course of their work wanted access to the test, even though doctors could not tell them its full significance. Appropriate resources had to be provided for that demand.<sup>169</sup>

### The evaluation project

**30.101** As noted above, unlike the USA, where kits had to be approved by the FDA before they could be used for screening, the UK did not have a requirement for test kits to be licensed under the Medicines Act 1968 or otherwise.<sup>170</sup> The DHSS had no statutory authority to force manufacturers to have their products evaluated before sale to the NHS was permitted.<sup>171</sup> There was thus no legal impediment to sale of such kits in the UK. Abbott were informed of that position on 5 March 1985.<sup>172</sup>

**30.102** The DHSS had decided that an evaluation of all the competing kits (including any developed in the UK) was necessary, however: it was seen as important that the most suitable tests were chosen for NHS use and that there was uniform introduction throughout the transfusion services.<sup>173</sup> As already noted in paragraph 30.50, Professor Tedder wrote to Dr Smithies on 18 December 1984, seeking funding for monitoring the efficiency with which the MH/CB test and the forthcoming commercial kits detected antibody to HIV.<sup>174</sup> It appears that by this stage the need for an evaluation of test kits in the specific context of the UK population had been recognised, although a specific date for a decision to that effect has not been identified. The intention behind the assessment was described as being to 'inform the NHS through suitable media of those products which were worthy of consideration. Thereafter the would-be purchasers could make a decision based on price and the results of appraisal with local circumstances in mind'.<sup>175</sup>

**30.103** On 16 January 1985, a draft of the evaluation programme was sent to Dr Smithies in the form of a letter to be sent to the producers of test kits.<sup>176</sup> The formulation of plans to conduct a detailed evaluation of test kits may have occurred in part during telephone conversations of which the Inquiry has no formal record. For example, the minute to Dr

<sup>175</sup> Notes of DHSS meeting [DHF.001.9250]

<sup>176</sup> Draft evaluation programme [DHF.001.9098] and minute [DHF.001.9097]. Compare the more developed protocol of 8 March 1985 [DHF.002.6939]

Smithies dated 16 January 1985 refers to 'our telephone conversation about setting up an evaluation programme'. What is evident is that a letter was sent by the DHSS to all those known to be developing tests, including Wellcome, around 21 January 1985.<sup>177</sup>

**30.104** The draft was discussed within the department and there was some consideration of whether only kits approved by the FDA should be 'accepted' in the UK. On 21 January 1985 Dr Smithies commented:

We also discussed whether or not any reference should be made to tests not being accepted in the UK unless they had FDA approval and decided that such stipulation might not act in Wellcomes best interests in the short term.<sup>178</sup>

**30.105** Professor Tedder commented:

There is little difference in having an American manufacturer or the FDA pontificating on the performance of a test and then accepting matters as gospel in this country. That would run completely counter to everything that we had ever done in the transfusion service in the UK and anything that we do nowadays. And indeed, if we had been tied to FDA ... we would have been locked into an antediluvian regulatory system.<sup>179</sup>

**30.106** The letter sent to manufacturers on 21 January 1985 made clear that the results of the evaluation exercise would form the basis of 'firm advice' to the NHS on which materials might be used and that it was likely that the NHS would also be advised not to use materials not tested in the programme.<sup>180</sup> The programme was to comprise a systematic study of each candidate material's performance against a panel of patients' samples, both positive and negative; investigation of the controls provided; and the convenience and time required to carry out each test. Information to substantiate claims made for each product would be required.

**30.107** All those manufacturing tests agreed to participate.<sup>181</sup> Wellcome responded almost immediately, replying on 29 January 1985 and agreeing to submit their product to evaluation but noting that their main priority was to make a kit available to the blood transfusion services as quickly as possible.<sup>182</sup> Professor Tedder interpreted the letter as indicating that, while Wellcome were willing to participate in the evaluation programme, they would not have prepared the usual, fully detailed portfolio of manufacturers' claims for its product and the data normally submitted for evaluation: there was not time to do that.<sup>183</sup>

**30.108** In Scotland, the SHHD were kept informed of developments. The DHSS submission to Ministers regarding the need to introduce screening into the NBTS was sent on 17 January 1985.<sup>184</sup> Dr Bell acknowledged receipt of these documents from Mr Murray by minute dated 21 January 1985.<sup>185</sup>

### *A potential conflict of interests*

**30.109** Initially, it was considered that Professor Tedder's laboratory might provide the evaluation service. The proposal that Professor Tedder and Professor Weiss should be funded to do this work was quickly dropped, however, when it was recognised that there was a potential conflict of interests in this approach.<sup>186</sup> As matters had developed, Professor Weiss and Professor Tedder had independent interests in promoting their distinctive technology in collaboration with Wellcome Diagnostics. On 11 February 1985, the DHSS wrote to Wellcome noting that commercialisation was a separate issue from the evaluation programme that was being set up.<sup>187</sup>

**30.110** The potential for a conflict of interests if Professor Tedder had been selected to do the evaluation was acknowledged in a DHSS memorandum dated 13 February 1985.<sup>188</sup> When he had sought funding, Professor Tedder had wanted to be able to look at the performance of the various kits in order to define the best algorithm for use, but that did not require extensive access to assays.<sup>189</sup> The full evaluation process would require much more access to assays while Professors Tedder and Weiss were, at the same time, working on their own test. Professor Tedder commented:

You know, I tore my hair out with our colleagues in DHSS over these early years. I think it's actually correct to have some form of Chinese walls because otherwise there is a conflict of interest, and I can't see how you can have a commercialisation of a test being carried out under the same umbrella as the evaluation programme. I think you do need to separate them because they are different issues.<sup>190</sup>

**30.111** Professor Tedder was anxious to avoid potential conflicts of interests. He was particularly concerned that no favours should be shown to his assay; his institution had financial interests in benefiting from its own intellectual property. He said that there had been no intention to delay the evaluation process to favour Wellcome and agreed with the refutation by Dr Barbara and Dr Hewitt that there had ever been any such idea.<sup>191</sup> Professor Tedder said:

Looking back I'm relieved that we were not asked to undertake such an evaluation, it would have been a massive deflection. It would also have constituted ammunition for the comment of conflicts of interest. I see ... the potential for a conflict of interest had we been asked to conduct an evaluation of commercially available assays while working with an industrial collaborator at the same time. To be in such a position would have rendered it extremely difficult for us to have meaningful conversations with the diagnostic firms concerned.<sup>192</sup>

<sup>186</sup> See paragraph 8.127 of the Preliminary Report for further details.

<sup>192</sup> Letter from Professor Tedder to the Inquiry dated 26 September 2011 [PEN.017.1831] at 1834

### *Preparatory work*

**30.112** On 13 February 1985 there was an internal DHSS meeting at which it was noted that Dr Mortimer had expressed a willingness to carry out an evaluation for the department and it was agreed that he would be acceptable to the DHSS.<sup>193</sup> At the time, Dr Mortimer was Director of the Central Public Health Virus Reference Laboratory of the Public Health Laboratory Service (PHLS). Dr Mortimer was selected to do the work<sup>194</sup> and an ad hoc Expert Working Group would be set up to help in the management of the evaluation.

**30.113** Professor Tedder said that there was a multiplicity of groups with different interests involved in monitoring the evaluation exercise.<sup>195</sup> There was a screening test sub-group of EAGA, which was to look at broader issues than the DHSS technical group, and the RTDs had a working party. By the time of the meeting on 13 February 1985, Dr Mortimer was drafting a protocol for the exercise.<sup>196</sup> The report of the evaluation exercise, dated September 1985, refers to the protocol having been drafted by an ad hoc Expert Working Group set up by the DHSS.<sup>197</sup>

**30.114** Dr McClelland said that, in his view, the ad hoc Expert Working Group established by the DHSS and the Screening Test Sub-Group of EAGA had ‘two completely different tasks’. The first group was ‘to design and possibly oversee the technical evaluation’, whereas the second was ‘to look at the broader group of issues for the transfusion service that had to be addressed in preparing to introduce large-scale screening testing of blood donors’.<sup>198</sup> Both groups played useful, timely and important roles as matters developed in 1985.

**30.115** On 15 February 1985, the screening test sub-group of EAGA met.<sup>199</sup> Dr McClelland had tabled a paper, dated 11 January 1985 and prepared by the Division of Biometrics of the FDA’s Department of Health and Human Services, reporting on phase 1 of the Public Health Service evaluation of US kits.<sup>200</sup> It was reported that the kits had not been tested by the participating companies on the same serum samples (a point made in the *Nature* article of 13 December 1984)<sup>201</sup> and it was agreed that it was essential to repeat the process in the UK using the same samples for each test. It was also agreed that the evaluation would have to embody confirmatory procedures and the requirements for field trials were discussed and agreed. The evaluation exercise would consist of initial testing by PHLS against a panel of sera with a follow-up evaluation in RTCs and in laboratories serving sexually transmitted diseases (STD) clinics also undertaken. Dr Gunson and Dr McClelland were asked to consider the feasibility of collecting samples and preparing aliquots from them at transfusion centres while Dr Pinching was to deal with STD clinics. It was noted that:

Regional Transfusion Directors had been unanimous in wanting a common date for the introduction of a test into the NBTS. The group considered that

individual RTCs should be dissuaded from implementing tests on a local basis. In fact it was agreed by the sub group that tests should better be made available for the clinical setting first.<sup>202</sup>

**30.116** The reference to 'NBTS' was intended to apply to the UK as a whole.<sup>203</sup>

### Development of the evaluation programme

**30.117** The EAGA sub-group met next on 1 March 1985.<sup>204</sup> Dr Gunson and Dr McClelland tabled a paper outlining a proposal for the second phase of evaluation, a BTS field trial using 10,000 specimens collected routinely from blood donors, to follow on completion of the PHLS evaluation coordinated by Dr Mortimer. Dr Pinching confirmed that he could collect the required specimens from STD clinics. There was general discussion of the technical problems involved and of the counselling and other services thought to be required.

**30.118** Dr McClelland described the plan to have a laboratory assessment of the kits using a smaller number of samples and then a field assessment as 'a fairly conventional sequence of events'.<sup>205</sup> Later, he said that the first stage, carried out by the PHLS and funded by the DHSS for the UK transfusion services, was a 'perfectly reasonable position for the first part of the evaluation'.<sup>206</sup> The second part of the evaluation then had to involve the transfusion services directly because 'that was the operating environment in which the test would have to be proven'.<sup>207</sup>

**30.119** An internal DHSS memorandum dated 11 March 1985 set out the anticipated arrangements for the introduction of screening tests.<sup>208</sup> All manufacturers known to be making diagnostic reagents had been informed that the DHSS intended to evaluate their kits and five had agreed to cooperate. The steps envisaged were:

- An initial evaluation against 300 to 500 serum samples by the Virus Reference laboratory at the PHLS Colindale.
- A field evaluation of the kits prompted by the experiences of the FDA as disclosed to the DHSS. This could not be started until completion of the initial evaluation. The required sera were already being collected and stored.
- The PHLS laboratories were to provide panels of standard sera and would provide a reference service.
- Kits satisfying the evaluation, including the UK test if produced on a large enough scale, would be listed.
- The Regional Transfusion Directors had agreed to commence testing at the same time and had indicated a wish to use the same test.

**30.120** On 15 March 1985, the DHSS wrote to the RTDs describing the two-phase programme then envisaged.<sup>209</sup> The letter commented that it was the intention of the Department to evaluate any commercially produced tests which were marketed and to

<sup>209</sup> See letter to Chairmen of RTDs, 15 March 1985 – DoH copy is to Bristol [DHF.001.9430]

give advice to the NHS on the suitability of the tests. It noted the view of the RTDs that there was an imperative need for a coordinated introduction of screening tests into all centres simultaneously, and EAGA's endorsement of that view, and that the view had been endorsed by Regional Medical Officers in discussion with the Department the previous day. The RTDs' interest in having a cohesive position was stressed at their meeting on 17 April 1985.<sup>210</sup> The DHSS was anxious that all blood transfusion authorities should wait until the results of the evaluation process were available and coordinated arrangements had been made to use the tests at all centres.

**30.121** It was considered very important that testing begin simultaneously throughout the UK. Dr Mitchell said that it was very clear that 'we were all to sing from the same hymn sheet' and he agreed with that approach.<sup>211</sup> Arrangements were in hand for the preparation of protocols for the evaluations and other procedural matters. Abbott's kit was to be tested and a small quantity was to be imported for that purpose. As the DHSS understood it, there were no kits in the UK at that point. Professor Cash observed that Dr Mitchell had not envisaged any problem in obtaining kits.<sup>212</sup> However, it is not clear that Professor Cash was well-informed about the availability of kits at the time.<sup>213</sup>

**30.122** 'Singing from the same hymn sheet' would not be easy: not all relevant agencies were up-to-date. The minutes of the meeting of the CBLA Central Committee for Research and Development in Blood Transfusion held on 2 April 1985 indicate that, until that date, the Chairman was not aware that UK evaluation studies of the tests had been set up or that a protocol for the evaluation had been sent to manufacturers.<sup>214</sup> However, in light of the information provided:

The importance of evaluation of the tests was emphasised and it was agreed that an adequate confirmatory laboratory service was required, especially in view of the high incidence of false positive results.

In answer to a question raised by the Chairman about testing in the haemophilic population in the UK, [Dr Rizza] and Professor Luzzatto informed the Committee of tests they had carried out in Oxford and at the Middlesex Hospital and the results of these had confirmed the importance of evaluation.<sup>215</sup>

**30.123** In Scotland, Dr McClelland prepared a paper dated 15 May 1985 for the RTDs, outlining some of the practical issues that would arise from the evaluation programme.<sup>216</sup> He emphasised the need for the evaluation of test systems in the light of evidence that some tests gave significantly lower false positive rates than others. He outlined the practical problems for Transfusion Directors in interpreting screening test results and in dealing with donors who were 'screen positive' on initial testing but unconfirmed and the need for confirmatory tests. He commented on the need for documentation and for communication with donors and donors' GPs, for the purposes of monitoring and counselling, among other matters. Dr McClelland's paper would have informed any Director who had been less than fully involved in the preparations for the evaluation programme of the range and

<sup>216</sup> Dr McClelland's paper [SNB.005.9600]

complexity of the preparations required, as well as providing a valuable check-list for all Directors.

**30.124** The views of Ministers were communicated to the PHLS on 31 May 1985.<sup>217</sup> It was intended to review the position on 7 June and the PHLS was asked to prepare a flow chart projecting dates for completion of the evaluation and for countywide introduction of testing, with take-up facilities for confirmatory testing. The PHLS prepared a flow chart and explanatory paper in June.<sup>218</sup>

**30.125** From the terms of the PHLS paper it appears that the initial evaluation process was not limited to Professor Tedder's work on the MH/CB test at the Middlesex Hospital and Dr Mortimer's wider exercise at the PHLS Virus Reference Laboratory, Colindale. Four other public health laboratories, at Newcastle, Leeds, Oxford and Birmingham, were testing for antibody to HIV.<sup>219</sup> Wellcome was developing the competitive MH/CB assay and Abbott, Electro-Nucleonics Inc, Organon, Litton/Ortho, Travenol and Production Pasteur were developing indirect assays. Abbott and Electro-Nucleonics Inc had said that they could supply the British transfusion and clinical markets immediately but both had withdrawn the kits originally delivered to the PHLS Colindale and supplied replacements, raising doubts about the claims. At Colindale, the first stage evaluation of Abbott, Electro-Nucleonics Inc and Wellcome test kits had begun with each company demonstrating their products. Colindale and Middlesex Hospital were proceeding to test the available assays. The summary of the paper suggested that the ideal position would be to have one UK kit (Wellcome) and one US kit available for use.<sup>220</sup>

***Concerns about perceived delay revisited: should US kits be introduced before evaluation is complete?***

**30.126** Among some haemophilia clinicians in the UK, including Professor Arthur Bloom,<sup>221</sup> there was still a degree of anxiety about delay. At the meeting of EAGA in May 1985, Professor Bloom expressed concern at delaying the introduction of a screening test in the blood transfusion service.<sup>222</sup> On 31 May 1985 he wrote to the chairman of the group to reinforce his views.<sup>223</sup> He was concerned for people with haemophilia, patients undergoing surgery, leukaemia patients and others needing blood and blood products, given the rising prevalence of HIV positivity. He thought that one or more of the FDA-approved tests should be introduced immediately for testing donations, leaving over re-testing, confirmatory testing and donor counselling to be dealt with as separate issues.

**30.127** At the meeting of the screening test sub-group of EAGA on 10 June 1985, there was a proposal to allow the three commercial kits due to have been evaluated by the end of June to proceed to the field test stage. However, the counter view – that it was better to wait until the PHLS had evaluated more tests, including that of Wellcome – appears to have prevailed.<sup>224</sup>

<sup>224</sup> See note of meeting of 10 June 1985 [DHF.002.7538] at 7539

**30.128** Professor Bloom continued to advance his similar suggestion. With Dr Forbes and Dr Charles Rizza (Director of the Oxford RTC), he wrote to the *British Medical Journal* (*BMJ*), his letter being published on 22 June 1985.<sup>225</sup> By this time, three commercial HIV screening kits had been approved by the FDA. The authors wrote:

[People receiving] whole blood, platelet transfusions, cryoprecipitate or other blood derivatives from 50 or more donors in a short space of time [may be exposed to the risk of HTLV-III infection]. The risk of HTLV-III infection in such patients could now be as high as one in 20 in certain areas of Britain.

All these considerations underline the need rapidly to introduce screening for HTLV-III antibody for all blood donations. Three commercial test kits have now been approved by the American Food and Drug Administration and, although there may be a small number of false positives, it is unreasonable to delay testing until this possibility is eliminated.<sup>226</sup>

**30.129** Professor Cash was angered by the letter. He drafted and distributed to Professor Bloom, Dr Forbes and Dr Rizza a severely critical response, but did not submit the letter for publication. He criticised them for publishing matters more appropriately discussed in established professional forums and speculated that they had done so in the hope of causing a media and public reaction (as, he said, had happened). He challenged as unfounded on any evidence the statement that the risk of HTLV-III infection in such patients could now be as high as one in 20 in certain areas of Britain and characterised as ‘an extraordinary and cruel distortion’ of the evaluation process the notion that it was concerned merely with logistical problems that could be dealt with after testing was introduced.<sup>227</sup> Though not noted by Professor Cash, Dr Rizza had been present at the meeting of the CBLA Central Committee for Research and Development in Blood Transfusion on 2 April 1985 when it was agreed that evaluation was necessary.

**30.130** Professor Cash sought to explain his position in oral evidence. He believed that there was a ‘major error of fact’ by Professor Bloom and his fellow authors in their letter relating to the assessment of the risk of false positives. Beyond that:

At the time I thought this is a direct attack on the UK transfusion services. And here we were battling away with our colleagues in DHSS to get the kits evaluated quickly, to get them into use. But Arthur [Bloom] didn’t seem to follow that, nor did Charles Forbes, so I reacted pretty angrily ....<sup>228</sup>

**30.131** The position of Professor Bloom and his co-authors was surprisingly close to the policy applied in the USA and at odds with the ethos of the UK blood transfusion services’ voluntary donor system. Professor Cash’s response is at least understandable, albeit expressed in particularly strong terms.

**30.132** The competing advice and representations of interest groups required discussion: the issue of whether US test kits should have been introduced as they became available was real. These exchanges illustrate deep divisions of opinion among those on whom official agencies would normally depend for independent advice.

<sup>225</sup> Bloom et al, ‘HTLV-III Haemophilia and Blood Transfusion’, *British Medical Journal*, 1985; 290:1901 LIT.001.0333]

<sup>226</sup> Ibid [LIT.001.0333]

<sup>227</sup> Professor Cash’s letter [SNB.013.2252]

<sup>228</sup> Professor Cash – Day 48, pages 113–114

**30.133** The factors that were most relevant to the issue whether to introduce US tests were clear:

- The anxiety of Professor Bloom and others to limit the risk of HIV transmission.
- The reliability of foreign (US) validations of test systems in the UK.
- The implication of a high rate of false positive results arising from use of the US kits.

**30.134** The DHSS was anxious that all blood transfusion authorities should wait until the results of the evaluation process were available,<sup>229</sup> although the CMO was concerned to monitor what was happening in other countries.<sup>230</sup> Not only was there monitoring of developments elsewhere, there was also pressure being brought to bear concerning the completion of the evaluation exercise.<sup>231</sup> It is also apparent that, during the process, two of the companies whose kits were involved in the evaluation withdrew material in order to replace one or other of the agents originally supplied.<sup>232</sup>

**30.135** At a meeting of the Central Committee for Research and Development in Blood Transfusion on 9 July 1985,<sup>233</sup> Professor Bloom said that, while he appreciated the need for a proper evaluation of the tests, his immediate priority, as a representative of ‘users’, was the protection of recipients of Factor VIII. He therefore considered that any undue delay in introduction of the tests would be unreasonable. That had been his consistent position. Since by July 1985 all Factor VIII used in the UK was heat-treated to exclude transmission of HIV, the specific risk he mentioned had been reduced, although risk remained at the same level for recipients of Factor IX. Recipients of blood transfusions also remained at risk. At the meeting, the state of play was described as follows under the heading ‘Anti-HTLV III Testing in the NBTS’:

The Chairman confirmed that ... [it] was his view ... that until a proper evaluation of the tests had been carried out within PHLS and the BTS the introduction of the tests should not be used for routine screening of blood donations. By not knowing the prevalence of antibodies in the donor population, the BTS was [as] yet unaware of the most effective test especially as far as false positive results were concerned. It was noted that 6000 donor samples were due to be tested at Edgware and Manchester and results would be analysed as the studies continued. Six PHLS laboratories in addition to PHLS Colindale were being set up as reference laboratories.

....

[Name redacted] informed the committee that excess plasma products released onto the market from BPL were likely to require licensing by FDA and, in addition, any intermediates shipped to other manufacturers could also precipitate inspection of BPL’s facilities and the plasma collection centres by FDA in due course. He said that part of the FDA requirement would be routine screening of donations by an FDA approved test for HTLV-III antibody. The Chairman said that it was possible that an FDA approved test was not necessarily the most appropriate for the BTS.<sup>234</sup>

*Political interest continues*

**30.136** The preference for having a British test evaluated as a possible candidate was referred to in a briefing note for the private office of the Minister of State on 30 May 1985.<sup>235</sup> In a further background note, 'Screening blood donations for HTLV III antibody', the CMO explained the need to evaluate the screening tests:

More than two million blood donations are collected each year and it is clearly essential to ensure that any tests introduced on this scale must be known to give consistent results and be specific and sensitive. Specificity in this context means that a test which does not give rise to an unacceptable number of false positives each of which would require extensive further investigation and would waste the blood donations involved. Sensitivity is also of paramount importance in order that no genuine positives should be missed.

While the commercial products already on sale have been evaluated elsewhere on an individual basis no comparative evaluation is available. This requires that their performance should be compared against a single carefully chosen panel of sera and that the tests should be conducted under controlled conditions. The PHLS are currently conducting such an evaluation. A field trial designed to explore both the specificity of the test and the operational aspects of its routine use throughout the country is also essential. Ease of use and consistency in large scale screening are prime requirements in selecting a suitable product for use in screening blood donations. Laboratory and field evaluations, both undertaken on a large scale, will enable an informed choice to be made and will promote confidence in those kits which are subsequently chosen .... It has been suggested that testing should be introduced immediately, before the reliability of the tests available has been evaluated. Early experience of other countries and the considerations outlined in this note have led Ministers to decide that it would be wrong to introduce a screening test until the further evaluations mentioned above have been carried out.<sup>236</sup>

**30.137** The need to introduce testing was also raised in the House of Commons when, on 27 June 1985, Kenneth Clarke, Minister of State for Health, gave a written reply to a parliamentary question. He stated:

[A] test will be introduced within the next few months to screen all blood given by blood donors for antibodies to the virus which causes AIDS ....

I understand and share the concern to get these tests in use as soon as possible. However, we must have tests which are accurate and can be trusted. A number of test kits are already available and in use abroad, but reports from those countries suggest that the tests are not entirely reliable. We believe that no test should be introduced in the United Kingdom until its reliability has been established. There is no point in introducing a test which often fails to detect antibodies in blood or detects antibodies where there are none. An evaluation programme is being undertaken by the Public Health Laboratory Service and National Blood Transfusion Service experts as a matter of urgency.... Contrary to reports in today's press, no decisions on choice of test kits have yet been made. We hope that we will be able to introduce a test within four to five months.<sup>237</sup>

<sup>235</sup> Briefing note [DHF.002.2283]

<sup>236</sup> Ibid [DHF.001.7376]

<sup>237</sup> Extract from *Hansard* [SGH.002.6798]

**Progress in the summer of 1985**

**30.138** Scottish officials knew of progress over the summer of 1985 as the evaluation process continued. On 8 July 1985, Dr Scott wrote to all Chief Administrative Medical Officers (CAMOs):

As you know the various tests for HTLV III antibodies are being evaluated; in due course routine screening and confirmatory tests will be recommended. It is probable that routine screening of blood donors will begin before the end of this year. Experience elsewhere has shown that in order to prevent people from presenting as blood donors solely to establish their antibody status the provision of alternative screening facilities is essential.

It would be helpful if you would inform the Department of how you propose to provide this facility.<sup>238</sup>

**30.139** On 11 July 1985, the working party of the Regional Transfusion Directors' Committee produced a report on the first phase of the evaluation exercise, entitled 'Screening of blood donations for anti-HTLV-III in regional blood transfusion centres'.<sup>239</sup> It narrated the agreement of the Regional Transfusion Directors' Committee of the NBTS and the SNBTS Directors' committee that routine screening tests for HIV should not be introduced until the following had taken place:

3.1 The proposed evaluation in the N.B.T.S. of different test kits has enabled satisfactory system(s) to be selected.

3.2 The establishment of Reference Centres for the purpose of carrying out nationally agreed confirmatory tests on sera giving positive results upon screening.

3.3 The establishment of alternative venues for anti-HTLV-III tests on members of the General Public who are not blood donors.<sup>240</sup>

**30.140** An amended report on the first phase of the evaluation programme (presented as paper EAGA (5) 6) was tabled by Dr Gunson at the fifth meeting of EAGA held on 30 July 1985, with an amendment to item 3.<sup>241</sup> Paragraphs 3.2 and 3.3 remained unaltered. The preamble, that routine screening tests for HIV should not be introduced until items 3.1 to 3.3 had taken place, was deleted and item 3.1 was amended to read:

3.1 That an evaluation in the N.B.T.S. of different test kits should be performed to enable satisfactory system(s) to be selected.<sup>242</sup>

**30.141** Dr Gunson explained that the working party recognised the pressure to introduce routine screening in the BTS as soon as possible.<sup>243</sup>

**30.142** The revised form of the report, probably reflecting growing concern about the time taken to complete the evaluation, recognised that there was a degree of urgency for the introduction of routine anti-HTLV-III screening of blood donations which precluded the

<sup>243</sup> Meeting minutes [SNB.001.0432] at 0435

completion of the NBTS second phase evaluation prior to arrangements being undertaken for the introduction of routine screening. The RTDs were being advised, therefore, to make arrangements with their respective Regional Health Authorities for the introduction of routine screening whilst the NBTS evaluation was proceeding, the selection of kits for use being made on the recommendations from the PHLS study. They were advised that long-term contracts with a particular manufacturer should be avoided until the results of the NBTS evaluation were available.<sup>244</sup> It was thought that by this means it might be possible to commence screening of blood donations by October 1985 and it was agreed that the introduction of the tests should take place throughout the UK over the shortest period practicable.<sup>245</sup>

**30.143** Professor Cash thought that the RTDs were concurring with the message that Dr Smithies had brought them.<sup>246</sup> However, there was more substance to the change than that implies. It appears to be reasonably clear that the discussion at the CBLA research committee meeting on 9 July was reflected in the change of emphasis within the report. Following the revised version of the report, the procedure was truncated. The NBTS would continue to evaluate tests but it would be local Directors who would carry out local evaluations and proceed to make arrangements to obtain kits for their regions. The full stage two evaluation was not completed.<sup>247</sup>

### Evaluation first round completed

**30.144** On 30 July 1985, it was announced, by way of a DHSS circular, that the first round of the evaluation was complete.<sup>248</sup> The fifth meeting of EAGA was also held that day and the Group considered the circular (tabled as paper EAGA(5)11) which would be issued to health authorities as a report on the evaluation of the kits.<sup>249</sup> The circular was sent to regional and district managers, scientific officers and medical officers among others. The recommendations from the exercise were attached. A more detailed account of the evaluation was to become available later. It was noted that the NBTS was undertaking its own second stage evaluation covering the aspects of use of the kits particular to the context of blood screening. Confirmatory testing was to take place at PHLS laboratories funded by the Department.<sup>250</sup>

**30.145** The kits had been tested against a panel of sera from unselected blood donors, from groups of patients with AIDS or AIDS-related diseases and from groups of patients in whom false positive results were a possibility. The kits recommended as most suitable for use in diagnostic laboratories were again Vironostika anti-HTLVIII (Organon Teknika Ltd), Wellcozyme anti-HTLVIII (Wellcome Diagnostics) and HTLVIII BioEnza Bead (Ortho Diagnostic Systems Ltd). These kits had provided a clear distinction between positive and negative results, had a low rate of false positives and gave reliable results with heat-treated sera. The later report of the first phase of the evaluation revealed that 220 samples from blood donors were used, as well as samples from those in high risk groups and those thought likely to give rise to false positive results.<sup>251</sup> Wellcozyme anti-HTLVIII

<sup>250</sup> Letter dated 1 August 1985 [SGH.002.6967]

<sup>251</sup> Public Health Laboratory Service and Department of Health and Social Security – Evaluation of Five Commercial Anti-HTLV III/LAV Assay Kits [SNB.004.8847] at 8852

and Vironostika anti-HTLVIII were considered to be particularly suitable for use in blood transfusion centres, being easy to use. These kits would be the first to be investigated in the second stage of the evaluation which was designed to investigate performance in large-scale screening of blood donors.

**30.146** The only documentation the Inquiry has in relation to the second part of the evaluation is a draft report about the second phase.<sup>252</sup> It is not clear when this draft was prepared, other than that it post-dates 5 September 1985 (a date referred to in the text). The second phase study at the Manchester and Edgware RTCs covered 6160 samples, using the two kits which had emerged as the leaders after the first phase of the evaluation. Not all of the 6160 samples were actually tested: the breakdown of samples tested at each centre is shown in a table.<sup>253</sup> Given that the document is described as a 'first draft', that it was written in September 1985 at the earliest and that there is no reference to it in the detail of the other information about testing from that time, it does not appear that this material was disseminated to assist Directors in their choice of kit before testing began in October 1985. In essence, the second phase of the evaluation exercise appears to have been truncated and information about it appears not to have been communicated before decisions about purchasing kits were made in the late summer of 1985. This was probably because, in Dr McClelland's words, 'additional delay was not acceptable'.<sup>254</sup>

**30.147** It was clear from Dr McClelland's evidence that, at least in retrospect, he found the evaluation process to have been less rigorous as a result of departure from the full two-phase plan.<sup>255</sup> Although it was not simply a matter of numbers, the quantity of blood donor samples that were included in the first phase was very small, particularly as a basis for conclusions on false positivity. A more robust estimate of false positives would have been provided by the second phase of the evaluation, though it would not have provided information about false negatives. Dr McClelland contrasted the use of tests in a hospital diagnostic context with their use in blood transfusion. The evaluation of a test for use where a patient is ill and there is a need to find out what is wrong was a different exercise from the evaluation of a test for the more problematic matter of scanning a very large part of the population, most of whom could be assumed to be healthy, for the purpose of picking out the very few who were not suitable as blood donors. Evaluation for blood transfusion purposes had been the focus for the second phase and Dr McClelland clearly thought it necessary for a valid decision, although he thought the decision to choose Wellcome was probably right. In the event, the report of the first phase of the evaluation process would prove to be the principal basis on which the candidate tests were identified as suitable for blood donors.

**30.148** Professor Cash was also concerned about the process. He thought that the rate of progress changed with the publication of Professor Bloom's letter to the *BMJ* of 22 June 1985. He expressed reservations about the appropriateness of the evaluations and opined that HIV screening was introduced in the UK without according the priority that he considered proper to the welfare of blood donors.<sup>256</sup>

### *Media controversy*

**30.149** On the other hand, there was some controversy in the media at that time as to whether the evaluation process had been delayed deliberately in order to allow Wellcome to catch up with the US companies. On 8 August 1985 the *New Scientist* reported the facts noted above: that the UK government had recently approved three AIDS virus test kits for use in diagnostic laboratories and that two, made by Organon and Wellcome Diagnostics, had been chosen to enter the second phase of assessment for daily use at blood transfusion centres in Edgware and Manchester.<sup>257</sup> According to the *New Scientist*, Abbott Laboratories accused the government of delaying approval until a British test was available.

**30.150** Abbott wrote to the editor on the same day to deny that they had made any such accusation.<sup>258</sup> The immediate response of the DHSS was sent out in a briefing note for Ministers dated 16 August.<sup>259</sup> On 22 August 1985 the *New Scientist* published a letter by Dr Tony Napier, Medical Director, Cardiff BTS, defending the policy in respect of the introduction of testing.<sup>260</sup> It was a spirited defence of the official position. As noted at paragraph 30.111 above, Dr Barbara and Dr Hewitt of the BTS at Edgware also wrote to the *New Scientist* on 29 August 1985, to similar effect.<sup>261</sup> A DHSS press release of 23 August 1985 intimated the introduction of testing by mid-October and the availability of new facilities for testing elsewhere.<sup>262</sup>

### **Local evaluation in Scotland**

**30.151** Organon and Wellcome kits became available in Scotland in about July or August 1985 for the purpose of evaluation and choice of kit for routine application and local evaluations followed.<sup>263</sup> In his written statement, Dr Dow explained the technical evaluation by the West of Scotland Blood Transfusion Centre: it performed a 'mini-evaluation' of the two kits recommended after the first phase of the evaluation, the Wellcome Diagnostics Wellcozyme assay and the Organon Diagnostics Vironostika assay.

**30.152** Dr Mitchell's views on the exercise were similar to those of Dr McClelland. He noted that the second phase of the evaluation was on 'a much smaller scale because ... the test materials were not available'. He said:

[A]t that time I think a number of people were saying, 'Look, hallelujah, let's get on, we have got something, let's look at it.' But remember... that the Mortimer study looked at 360-odd samples, which were selected. Some of them were pretty obviously going to be positive, they were known cases of the disease, whereas when you had to scale that up to the point of technical know-how – Mortimer's group was a group of very eminent virologists, who didn't run a blood transfusion centre, didn't run anything to do with blood transfusion.

<sup>257</sup> 'Ministers delayed launch of AIDS test', *New Scientist*, 8 August 1985 [DHF.001.7660]. At the Conference on AIDS in Newcastle in February 1986, it was stated that the evaluation at Edgware and Manchester had revealed several interesting findings but was still to be finalised. <sup>262</sup> DHSS Press Release [DHF.001.7729]

<sup>263</sup> Dr Mitchell – Day 51, page 40

What they said was good, their evaluation was very thorough, and I don't think we could have done it at that level of virology, molecular virology. But at the same time 300-odd samples did not really add up to mass screening.

And we had to evaluate – they were telling us what to do but we knew how to do it, if you know what I mean.

....

But, in the knowing how to do it, there was a considerable amount of work still needed to be done. We had to do all sorts of things about sample identification, computerisation, all sorts of things. My centre was the first one in the world to have a computer on line to ... test the system.<sup>264</sup>

**30.153** The results of the mini-evaluation favoured the Wellcome kit and it was therefore chosen for use in the west of Scotland. In the event, after the commencement of screening, as explained by Dr Dow, staff in the west experienced 'horrendous problems with plate validation failures'. The test kit was less sensitive than the original (developmental) version which they had evaluated in July 1985.<sup>265</sup> Dr Mitchell commented:

I think, if I remember rightly, the early samples that we got were good, they were fine, and we could detect known positives and known negatives and so on with the small amount we got, but when that was scaled up, then we ran into all sorts of difficulties ... [and] that's an example of where what looks good suddenly goes bad in your hand when you scale it up. You see, a virology department has all the time in the world – I don't mean that literally, but lots of time to look at a thing: Two hours, two days, four days, next week .... That's fine.

....

Blood transfusion has to get this stuff on the shelves this afternoon .... When you start scaling it up and you discover that you have got to repeat your tests over and over and over again on the same day to get any sense out of it – that is that the manufacturer's own controls are working okay as against the samples, to be sure the results are genuine – then you begin to see, 'My goodness, this isn't really fit for purpose at the moment'.<sup>266</sup>

**30.154** In the first few months of testing, the West of Scotland centre also used some Abbott kits, which were provided by Abbott free of charge in the hope that the poor specificity found in earlier studies (and during use for diagnostic purposes in Ruchill Hospital around March/April 1985) had been resolved.<sup>267</sup> In Dr Dow's laboratory, however, the Abbott kit proved less specific than the Wellcome kit and it was not considered suitable as a replacement.<sup>268</sup>

<sup>265</sup> Dr Dow's Statement [PEN.017.1680] at 1683

<sup>266</sup> Dr Mitchell – Day 51, pages 44–45

<sup>267</sup> Dr Dow's Statement [PEN.017.1680]. There is contemporaneous correspondence referring to evaluation/use at Ruchill: letter dated 11 February 1985 from Abbott Diagnostic Products GmbH to DHSS [DHF.001.9169]. See also confirmation that this was infectious diseases testing: Professor Cash – Day 48, page 95

<sup>268</sup> Dr Dow's Statement [PEN.017.1680] at 1684

**30.155** The third meeting of the EAGA ad hoc working group on evaluation took place on 25 September 1985. The conclusion then, after the further evaluation at Manchester and Edgware, was that both recommended kits were suitable for the routine screening of blood donations<sup>269</sup> although some reservations were expressed about the operation of each.<sup>270</sup>

### Other necessary steps: the ‘magnet effect’ and confirmatory testing

#### *The ‘magnet effect’ and alternative testing sites*

**30.156** There was, as previously noted, some concern about a possible ‘magnet effect’ once screening of blood donors for HIV was introduced. The concern was that individuals who feared that they might have become infected would donate blood simply in order to be tested for HIV. The solution to that anticipated difficulty was to ensure that there were alternative testing sites, where worried individuals could access testing in as straightforward a manner as possible.

**30.157** Dr McClelland described the reasoning behind the requirement for alternative testing facilities:

Our concern was that a lot of individuals would be extremely reluctant to go to the GP.... [W]e had good reason for that concern, and equally other people, you know, might also be reluctant to go to what would then have been called the ‘VD clinic’. It didn’t have a fantastically good image amongst some people.

....

So we wanted to have this completely neutral [facility]. And we wanted to be able to actually publicise it, and ... to disseminate information as widely as possible that this facility was available.<sup>271</sup>

**30.158** He commented further that ‘it was one of our absolute objectives that this should be operating and open for business before we started our donor testing’.<sup>272</sup>

**30.159** Professor Cash had written to Mr John Mutch of the CSA on 26 February 1985, urging him to liaise with his counterparts in Area Health Boards on this issue.<sup>273</sup> This point was discussed at the meeting of EAGA on 30 July 1985.<sup>274</sup> Dr Graham Scott, Deputy Chief Medical Officer (DCMO) in Scotland, had written to the CAMOs on 8 July 1985, asking for details of the arrangements they had made to secure alternative testing sites.<sup>275</sup> That letter referred to an earlier letter of 16 April 1985, copied to all CAMOs, mentioning that ‘Health Boards should consider what facilities should be made available for testing persons other than bona fide blood donors’.<sup>276</sup> Further information about the need for alternative sites and for counselling of those found to be positive was communicated in a letter from Dr Scott to the CAMOs dated 14 August 1985; it was ‘essential’ that the

<sup>269</sup> Organon’s Vironostika indirect ELISA; and Wellcome’s Welcozyme competitive ELISA.

<sup>271</sup> Dr McClelland – Day 50, page 57

<sup>272</sup> Ibid page 58

<sup>273</sup> Letter [SGH.002.7266] and enclosure [SGH.002.7267]

<sup>274</sup> Minutes of meeting [SNB.001.0432]. See also: letter of 22 August 1985 from Professor Cash to DHSS [SNB.001.0430]

<sup>275</sup> Letter [PEN.017.0567]

<sup>276</sup> It has not been possible to locate a copy of this letter, although its content can be deduced from the later letter. Details of the research conducted by the Scottish Government on this topic are set out in a letter dated 18 August 2011 from the Scottish Government to the Inquiry [PEN.017.0565]; evidence on the matter was also given by Dr Scott – Day 49, pages 117–124

arrangements made by each Health Board were finalised and publicised before the end of September.<sup>277</sup>

**30.160** The Inquiry also obtained information from Dr Ray Brettle, a retired Consultant Physician at the City Hospital in Edinburgh. Dr Brettle confirmed that his recollection was of the City Hospital Screening Clinic for HIV starting operation in October 1985.<sup>278</sup> The Inquiry asked Dr Mitchell what equivalent facilities existed in Glasgow but Dr Mitchell's recollection was that individuals seeking a test for AIDS at that time would have required to go either to their GP or to one of the specialist clinics (a drug users' or genito-urinary medicine clinic).<sup>279</sup>

**30.161** There was no evidence that the need to establish alternative testing sites delayed the introduction of screening of blood donors. There was some evidence obtained after the commencement of screening that blood donation would indeed have been used by some worried individuals to obtain a test, had there not been other facilities available.<sup>280</sup>

### *Confirmatory testing*

**30.162** Another factor that had the potential to disrupt progress, but was resolved, was the selection of a laboratory for confirmatory testing.

**30.163** Dr McClelland was asked whether it would have been possible to introduce screening without confirmatory testing being available, with the result that donations testing positive on initial screening would be discarded and that there would be no further use of donations from that donor. Dr McClelland explained that, at the time, the view was taken that donors should not be tested without being told and that positive results should be communicated to them. Donors should not, however, be informed that their result was positive unless it was beyond reasonable doubt that a result was a true positive rather than a false positive.<sup>281</sup> In his view, it was necessary to be 'completely upfront and open' with donors about testing<sup>282</sup> and confirmatory testing therefore had to be in place before screening started. That view was common.<sup>283</sup>

### **Adoption of the United Kingdom decision in Scotland and Ministerial approval**

**30.164** This section deals with the process by which Scotland came to follow the UK model in and after January 1985.

**30.165** As noted already, the DHSS had decided that an evaluation of the competing kits for screening of donated blood for AIDS (including any developed in the UK) was necessary, so that the blood transfusion services could be advised as to which tests were most suitable for them.<sup>284</sup> The DHSS submission to Ministers in England and Wales was copied to the SHHD in January 1985. On 7 February 1985, Mr Davies sent a minute dealing with the issue to Dr Scott, DCMO, and copied it to Mr Macpherson, Mr Robertson and Dr McIntyre, colleagues at the SHHD. He wrote:

<sup>277</sup> Letter [SNB.004.9017]

<sup>278</sup> Letter from Dr Ray Brettle to CLO re: City Hospital Screening Clinic for HIV [PEN.017.0682]

<sup>279</sup> Dr Mitchell – Day 51, page 53

<sup>281</sup> Dr McClelland's Witness Statement [PEN.017.1337] at 1363

<sup>282</sup> Dr McClelland – Day 50, page 82

<sup>283</sup> See, for example, a DHSS letter to Health Service Managers in England and Wales dated 1 August 1985 [SGH.002.6967] and the DHSS/SHHD booklets published in October 1985, discussed at paragraph 30.196 below.

<sup>284</sup> See letter to all kit manufacturers dated 21 January 85 – an example is [DHF.001.9140]; see also a briefing note dated 21 February 1985 by Professor Cash for the Chairman of EAGA [SNB.001.0162]

DHSS Ministers have now agreed (apparently with great reluctance) that all donations of blood in England should be tested for the presence of antibodies to HTLV-III. We now have to decide whether we have any alternative to advising our Ministers that it is necessary to follow suit in Scotland.<sup>285</sup>

**30.166** He referred to experience to date and outlined the safety procedures already in place. He suggested that donor selection measures being implemented should reduce the number of infected donations, which he said was already 'vanishingly small'. He correctly concluded that people with haemophilia were not at risk, due to heat-treatment of Factor VIII, but perpetuated the misconception – then widely prevalent – that only a small proportion of those with antibodies would develop AIDS, from 10% down to one in several hundred. He proceeded:

Also, as you yourself have said, there is a considerable danger that people considering themselves at risk may attend blood donor sessions specifically for the purpose of having their blood tested.

....

It seems to me that the balance of rational argument would be heavily against introducing a test on all donations. I accept, however, that there is little rationality to be seen where AIDS is concerned .... I should be grateful for your guidance as to what we should tell Ministers.<sup>286</sup>

**30.167** The next day, Dr Scott sent a reply to Mr Davies' minute. He commented:

Testing for HTLV III antibodies is technically different from testing for hepatitis B antigen. In addition, the test is much more expensive as well as being seriously unreliable. Until a test which identifies the virus itself is available matters will remain unsatisfactory.

From a cold objective scientific viewpoint the case for the introduction of a test for HTLV III antibodies in the present state of development and without being properly validated is not clear cut .... It is most unfortunate that a policy decision on this matter was not made at a UK level, though understandable given the degree of public and media hysteria.

It would be helpful if we could have an office meeting to discuss our advice to Ministers. It is for consideration whether Dr Cash ... might also be invited to the office meeting; if he strongly advocated introducing the test despite its limitations the Minister would be open to criticism if he did not agree to the introduction of the test.<sup>287</sup>

**30.168** Mr Macpherson also replied to Mr Davies' minute.<sup>288</sup> He took a more pragmatic line: if England introduced the test, it would be difficult for Scotland not to introduce screening. Although he accepted the validity of Mr Davies's comments, he thought that the pressure to follow the English example and introduce testing would be irresistible.

---

<sup>285</sup> Minute [SGH.002.7295]

<sup>286</sup> Ibid [SGH.002.7295]

<sup>287</sup> Minute [SGH.002.7294]

<sup>288</sup> Minute [SGH.002.7293]

**30.169** On 21 January 1985, Dr Bell of the SHHD gave his response to the DHSS submission. Although the matter was for the SNBTS, Dr Bell apparently envisaged that Scotland would follow the same approach as the rest of the UK.<sup>289</sup> Dr Bell was well informed of developments in England and it is implicit in his letter that the real issue for Scotland, although the matter was for the SNBTS, was which test method would be adopted in Scotland.

**30.170** In oral evidence, Dr Scott agreed with the suggestion that the tone of Mr Davies' minute suggested that he was not terribly sympathetic to the idea of introducing screening. He commented, however, that if it were to go ahead, finance was not going to be a problem: that had been cleared.<sup>290</sup> At the Inquiry's Oral Hearings it was noted that, at the date of the letter, Factor IX was not heat-treated and that, therefore, Haemophilia B patients remained at risk. Dr Scott was unable to comment on Mr Davies' state of knowledge at the time.<sup>291</sup>

**30.171** The Regional Transfusion Directors met on 23 January and 18 February 1985. Dr Smithies and Mr Williams attended after the close of business at the reconvened meeting on 18 February and provided unspecified information on testing.<sup>292</sup>

### *Scottish evaluation*

**30.172** Within the SNBTS, it was agreed at a meeting of the Co-ordinating Group on 19 February 1985 that no Transfusion Centre in Scotland would commence routine donation testing for HIV unilaterally under any circumstances, whatever pressures might be applied. It was hoped that there would be a Ministerial statement to the effect that testing would not be introduced for blood donations until the tests were likely to yield more accurate results.<sup>293</sup> The decision was noted at the meeting of SNBTS Directors which followed on 27 February 1985.<sup>294</sup>

**30.173** Abbott kits were available for evaluation in March 1985. At a meeting between the SNBTS Directors, Haemophilia Directors and the SHHD on 7 March 1985 dealing with AIDS, including heat treatment, Dr McClelland reported on plans for the new US screening tests for HIV antibodies to be evaluated on a UK basis.<sup>295</sup> He reported that, at that stage, there was deep concern about reports indicating a high proportion of false positive tests in the trials carried out in the US. The Inquiry has not found evidence of marketing of test kits as early as March 1985: rather, test kits were available in small numbers for evaluation purposes only. Abbott kits were used, and evaluated in use, in virology laboratories in Glasgow and Edinburgh as a start to providing an HIV testing service, not as a blood donor screening service.

**30.174** The concern in Scotland, and the rest of the UK, about the high incidence of false positive results was in marked contrast to the position in the USA, already noted, which was tolerant of false positive results in those early US test systems.

<sup>289</sup> Minute [SGH.002.7301]

<sup>290</sup> Dr Scott – Day 49, page 132

<sup>291</sup> Ibid pages 132–133

<sup>292</sup> Minutes of meeting [SNB.011.1971] at 1976–78

<sup>293</sup> Ibid [SNB.003.9171] at 9177

<sup>294</sup> Minutes of meeting [SNB.002.3507] at 3509

<sup>295</sup> Minutes of meeting [SNF.001.0241] at 0242

**30.175** Some in the SHHD continued to have reservations as to the necessity for blood donor screening: a draft memorandum of 21 February 1985<sup>296</sup> suggesting that policy in Scotland should avoid the early introduction of testing became a final recommendation to that effect on 21 March 1985, when the office meeting proposed on 8 February 1985 took place. In respect of tests, the revised memorandum noted:

Tests are becoming commercially available for the screening of blood donations for the presence of HTLV III antibodies. The first of these tests, from the USA, was marketed in the UK at the beginning of March. DHSS Ministers have agreed in principle that, in England, all blood donations should be screened and that Regional Health Authorities should meet the cost of this. Regional Blood Transfusion Directors throughout the UK have written to the *Lancet* ... strongly supporting the screening of all blood donors, but advising that such a screening programme should be delayed until the available test systems have been evaluated and until alternative testing facilities are made available to individuals who may be at high risk of transmitting AIDS.

We consider these views of the Transfusion Directors to be sensible and responsible, and support them, particularly in the Scottish context ....

The tests becoming available from United States companies are likely to give a high rate of false positive results – maybe 4%. On that basis about 10,000 ... Scottish blood donors could be identified as having antibodies to HTLV III who are in fact quite free of them. The implications for the individuals concerned, and for the resources required for further testing and counselling, would be profound and substantial. The tests also have an unpredictable false negative rate, so that an infected person might not be identified; and since the test is for antibody and not antigen it will not in any case identify a person who has been infected with the antigen but not yet developed antibodies.<sup>297</sup>

**30.176** The submission, which discussed the possibility of making AIDS a notifiable disease as well as the introduction of screening of blood donations, went to Scottish Ministers on 21 March 1985. A copy of the Transfusion Directors' letter in *The Lancet* was attached and their recommendation of an evaluation process and the establishment of alternative testing facilities as pre-conditions for the introduction of screening was highlighted and supported. The perceived drawbacks of testing were mentioned: false positive results, with consequent effects on donors and needless loss of donations, false negative results, cost and the 'magnet effect' (discussed at paragraphs 30.156–30.161 above and paragraph 30.194 below). The recommendation was that a phased policy leading to routine screening should be pursued, taking into account the results of the evaluation, the need for alternative testing facilities and the requirement for additional testing and counselling of donors.

**30.177** Mr John Mackay's private secretary responded by telex on 22 March 1985.<sup>298</sup> Mr Mackay, at that time the Scottish Health Minister,<sup>299</sup> fully appreciated the logic of the advice, especially that 'at risk' men might use the transfusion service as a screen. The recommendation of alternative testing sites was 'essential'. He observed that Scotland had to keep in line with, or ahead of, England to avoid severe criticism.

<sup>296</sup> Draft memorandum [SGH.002.7282]

<sup>297</sup> Revised memorandum [SGH.002.7226] at 7227–78

<sup>298</sup> Telex of 22 March 1985 [SGH.002.7225]

<sup>299</sup> Under-Secretary of State for Scotland with responsibility for Health and Social Work.

**30.178** The views of George Younger, Secretary of State for Scotland, followed on 26 March 1985: the Secretary of State also 'agreed the recommendation'<sup>300</sup> and a decision in principle to proceed with screening had been reached by this point, in March 1985.<sup>301</sup>

**30.179** In Oral Hearings, it was suggested to Dr Scott that the advice to Ministers reflected a lack of urgency regarding the introduction of screening on the part of the SHHD at this time. Dr Scott did not accept that proposition.<sup>302</sup> Scottish Ministers took the view that screening should be introduced as Mr Mackay's telex had indicated.

**30.180** At this stage, the CMO for Scotland was, in Dr Scott's term, an 'absentee landlord', often away from Scotland on business for the World Health Organization at which times Dr Scott acted on his behalf. It therefore fell to Dr Scott to follow up the Ministers' decisions. It was Dr Scott's view that it would not have been correct to introduce a screening test before it had been evaluated, because of the risk of false results among other things.<sup>303</sup> As noted above, on 16 April 1985 he wrote to all CAMOs commenting that health boards should consider what facilities should be made available for testing persons 'other than bona fide blood donors'.<sup>304</sup> Implementation, as in England, was seen as a matter for the local health authorities.

**30.181** On 28 June 1985, the SNBTS Directors again discussed the introduction of testing for HTLV-III antibody.<sup>305</sup> Dr Gunson had been invited to attend the meeting and he described the operation of the UK trial of FDA-licensed kits in his own Centre and at Edgware.<sup>306</sup> The kits to be made available for routine screening would be selected from those currently on trial. Dr Gunson agreed to notify Professor Cash in due course which were the likely tests and the Scottish Directors could choose, if they wished, to evaluate them in their own Centres. The Directors acknowledged the need to choose a screening methodology suited to each Centre. It was agreed that the reference centres for confirmatory testing for Scotland would be the laboratories of Professor Morag Timbury (Glasgow) and Professor Gerald Collee (Edinburgh).<sup>307</sup>

**30.182** Dr Gunson explained the work of EAGA, which had established working parties on the counselling of donors and on HTLV-III antibody testing.<sup>308</sup> It had been concluded that a test could be considered positive if it was still so after initial screening, re-testing by the same technique, a test of a sample from the donation itself<sup>309</sup> and after further testing by the reference laboratories.

**30.183** There was discussion of the issue of informing donors. It was agreed that:

[D]onors should be informed that their donations would be HTLV-III [antibody] tested and should indicate by signing they had understood this.

[T]he first contact (counselling) of all confirmed antibody positive donors would be the BTS medical staff.

<sup>300</sup> Telex of 26 March 1985 [SGH.002.7224]

<sup>301</sup> Dr Scott – Day 49, page 117

<sup>302</sup> Ibid page 143

<sup>303</sup> Dr Scott's Witness Statement [PEN.017.0513] at 0514

<sup>304</sup> The Inquiry has not recovered this letter. See a letter from Dr Scott to Chief Administrative Medical Officers in which he refers to his earlier letter dated 16 April 1985 [PEN.017.0567]

<sup>305</sup> Minutes of meeting [SGF.001.0203]

<sup>306</sup> Ibid Item 3 (d) ii. [SGF.001.0203] at 0205

<sup>307</sup> Ibid Item 3 (d) v. [SGF.001.0203] at 0206

<sup>308</sup> Ibid Item 3 (d) vi. [SGF.001.0203] at 0206

<sup>309</sup> Presumably a fresh sample from the donation to exclude the risk that there may have been contamination of the test sample.

That BTS doctors would use their best efforts to encourage donors to agree that their GPs/ dentists be informed by BTS of their positive [antibody] status.

That BTS medical staff would ensure the establishment of appropriate counselling and medical follow up of [positive] donors.

The BTS would take steps to track the recipients of [antibody] positive blood products produced at RTC's by informing the consultant responsible for the care of the patient. All subsequent actions would be determined by the clinician.<sup>310</sup>

**30.184** Dr Gunson wished to see an agreed SNBTS approach so that he could table it for discussion at the next meeting of the NBTS Directors.

**30.185** It was agreed that the ideal would be to retain donor samples as long as possible. Professor Cash was investigating the matter of a central library of samples for Scotland; meantime, all samples would be retained pending the introduction of testing.<sup>311</sup>

**30.186** Finally, a system for Scotland for laboratory reporting of HTLV-III positive antibody tests would be agreed with the Communicable Disease (Scotland) Unit.

**30.187** Practical arrangements to introduce screening and to deal with the associated issues were then made.<sup>312</sup> On 2 August 1985, Professor Cash sent a letter to all Directors, setting out a very detailed summary of the issues and a 'countdown' to testing.<sup>313</sup> The detail of arrangements was canvassed in evidence with Dr McClelland, who described Professor Cash's letter of 2 August 1985 as 'very good briefing'.<sup>314</sup>

**30.188** Professor Cash noted the need to plan for the introduction of screening and advised that the target should be to introduce testing slowly, on a selective basis and at a low level of activity in the later weeks of September, so that the move to full screening in early October would be an operationally smooth exercise.<sup>315</sup> He advised that initial contracts for supplies of kits should be short-term, in order to give flexibility to change suppliers if that should prove necessary. He also encouraged the use of both available kits with a view to obtaining advantage in price negotiations and set out a range of practical guidance for implementing testing. It was a comprehensive briefing, while leaving decisions open for individual Directors in respect of their own regions. On 7 August 1985, Dr McClelland assigned tasks to staff; there was a staff meeting on 19 August 1985 to discuss implementation; and there was a decision to commence routine testing on 23 September 1985.<sup>316</sup>

**30.189** Meantime, Dr Scott had received copies of the DHSS documents and distributed them to the CAMOs and to Professor Cash on 6 August 1985.<sup>317</sup> For confirmatory testing in Scotland, Dr John Peutherer in Edinburgh would handle Southeast (Edinburgh), East (Dundee) and Northeast Scotland (Aberdeen), and Dr Edward Follett in Ruchill would handle Glasgow and Inverness.<sup>318</sup>

<sup>310</sup> Minutes of Meeting: Item 3 (d) vi. [SGF.001.0203] at 0206

<sup>317</sup> Letter [SGH.002.6982]

<sup>318</sup> Dr McClelland – Day 50, page 68

**30.190** On 14 August 1985, Dr Scott again wrote to CAMOs and to Community Medicine Specialists with an up-to-date report on progress.<sup>319</sup> To achieve screening of blood donations from mid-October, it was said to be essential that alternative testing facilities should be in place by the end of September. The letter noted that genito-urinary/STD clinics had relevant experience and would be suitable facilities but that there was also a need to provide for those who did not regard themselves as appropriate clients for such clinics. He advised that GPs had to know the local arrangements and that courses were available for training at St Mary's Hospital in London. Attached to the letter were copies of the guidelines produced by the DHSS Expert Advisory Group on AIDS. There was also reference to further advice yet to be circulated. Dr Scott commented that there would be an opportunity for general discussion at the meeting of the CAMOs and the CMO to be held on 4 September 1985.

**30.191** A scoping exercise was carried out on 19 and 20 August 1985 by a group from Edinburgh and by the Transfusion Directors' Co-ordinating Group.<sup>320</sup> There was to be an evaluation of the Organon and Wellcome kits before selection; the NBTS information on false positive results would be reviewed; and it was noted that there was no commitment to having a single kit for use by the SNBTS. After completion of the evaluation, the SNBTS would move directly to testing incoming donation samples. The practical start date of 23 September 1985, before the official start date in October, was confirmed.<sup>321</sup>

**30.192** In the South-East BTS region, proposals for the study of alternative venues for screening were submitted for grant on 18 September 1985, as a pilot for other health boards.<sup>322</sup> It appears that the work was already well advanced, since the clinic required was in operation at the Infectious Diseases Unit at the City Hospital, Edinburgh before the commencement of routine screening by South East BTS.<sup>323</sup>

**30.193** On 20 September 1985 Mr Liddle of the SHHD distributed a minute on AIDS to Scottish Ministers and to senior colleagues, including the CMO, the Director of the Prison Service and the Director of the Scottish Information Office. The purpose of the minute was to provide an update on Mr Macpherson's minute of 21 March and Mr Davies' minute of 28 June. It noted:

The testing of blood for the detection of HTLV-III antibody, whether by the NHS or by the Blood Transfusion Service is to commence in mid-October and we have impressed on Health Boards the importance of adequate publicity being given to the facilities available outside the Blood Transfusion Service. However, there is a likelihood of a Ministerial Statement ....<sup>324</sup>

**30.194** The decision had been taken. The commercially available test kits had been evaluated by a panel of experts from the PHLS and a summary of the results had been made available to health boards. Confirmatory testing of positive donations was in hand. A start date of mid-October had been fixed.<sup>325</sup> In addition:

<sup>319</sup> Letter [SNB.004.9017]

<sup>325</sup> Ibid [SGF.001.0831]; 'Countering the Spread of AIDS in Scotland' [SGH.002.7072]

- The cost of confirmatory testing was being met through the Advisory Group on New Developments in Health care; health boards were to absorb the cost of screening facilities but the 1985–86 revenue allocation for the SNBTS had been increased by £322,000 to provide for the purchase of screening test kits.
- Steps were to be taken to provide NHS facilities to protect the SNBTS from the ‘magnet effect’.
- Counselling was to be provided.

**30.195** Wellcome were in a position to provide kits to allow routine donor testing at Ruchill in mid-September 1985. The West of Scotland BTS had problems with plate validation failures, as already noted at paragraph 30.153. It was apparent that the production kit was less sensitive than the original (developmental) batch tested in July 1985. The report of the results of field tests of the kits in England and Wales also produced mixed results.<sup>326</sup> Scottish scientists managed to overcome these validation difficulties, for which Wellcome were grateful.<sup>327</sup>

### *Final preparations*

**30.196** A press release on 1 October 1985 announced the screening of all UK blood donations from mid-October 1985 and emphasised how important it was that those who believed themselves at risk refrain from donating blood simply in order to be tested.<sup>328</sup> The DHSS published a booklet, distributed on 1 October 1985, containing information for doctors concerning the introduction of the HIV antibody test.<sup>329</sup>

**30.197** The covering letter, signed by Dr Donald Acheson, CMO, emphasised the continuing need for exclusion of high risk donors, noting that even a reliable test could not detect early infections to which antibodies had not yet been generated.<sup>330</sup> The booklet stated that the tests were being introduced routinely to screen all blood donations. Donors were to be informed that the test was being done and would be asked to agree before blood was taken. It was explained that the tests introduced had been the subject of careful evaluation by the PHLS and the NBTS.<sup>331</sup>

**30.198** Blood testing positive would not be used for transfusion. The blood was to be re-tested and a sample sent to a Reference Laboratory for testing by ‘another test method’. On confirmation by this procedure, the donor was to be contacted and called in for discussion and counselling. The booklet emphasised that counselling had to be careful: it was still thought that not all those who seroconverted would progress to AIDS and that there would be less serious outcomes for many, although all who seroconverted had to be considered capable of transmitting the disease through sexual contact or through transfusion or inoculation of blood. A further blood sample would be taken for confirmatory testing. The risks of false positives and false negatives were highlighted but fully confirmed positive tests were to be followed by an offer of full clinical evaluation. Doctors were told of possible clinical signs and symptoms.<sup>332</sup>

<sup>326</sup> ‘An Evaluation of Anti-HTLV III Test Kits in the National Blood Transfusion Service’ – Report of the Results on the First and Second Test Kits [DHF.002.9428]

<sup>327</sup> Dr Dow’s Witness Statement [PEN.017.1680] at 1683; Professor Cash – Day 48, page 68

<sup>328</sup> Press release [SGH.002.7099]

<sup>329</sup> Covering letter dated 1 October 1985 and a copy of the booklet [SGH.002.7091]

<sup>330</sup> Ibid [SGH.002.7091] at 7092

<sup>331</sup> Ibid [SGH.002.7091] at 7093

<sup>332</sup> Ibid [SGH.002.7091] at 7093-94

**30.199** The booklet reflected the general perception of the disease at the time: seropositive patients were likely to react badly to confirmation that they were infected with HIV. Quite apart from longer-term prognoses, life patterns would be affected immediately and the risk of adverse reactions from the public and employers was also anticipated. The booklet prescribed procedures for the collection and laboratory testing of samples and for the protection of health workers. It also dealt with confidentiality:

The strictest confidentiality must be maintained when an HTLV III antibody positive individual is identified. Where a person is tested for HTLV III infection or for its complications and it is thought to have been sexually transmitted, health authorities have an obligation to maintain confidentiality of information under the terms of the National Health Service (Venereal Diseases) Regulations 1974 (SI 1974.9). Unless the patient has given his consent, personal health data relating to him must not be disclosed to anyone for any purpose other than the health care of that patient, except where the disclosure is necessary to prevent the spread of infection. Disclosure of this information for purposes other than medical or public health reasons could lead to serious consequences for the informant. Adequate safeguards to protect individuals against unauthorised disclosure must be adopted.<sup>333</sup>

**30.200** Appendix 1 of the booklet dealt with 'Laboratory Investigations'. Appendix 2 dealt with 'Guidance to individuals on measures to control the spread of HTLV III'.

**30.201** The booklet was adapted for use in Scotland.<sup>334</sup> It noted the arrangements made by the SNBTS for screening and the alternative testing facilities available through GUM and STD clinics. As in the case of the English booklet, it outlined the procedures to be followed with positive donations and advised caution in the light of the risk of false positive results. The importance of alternative facilities to prevent people donating blood simply to determine their antibody status was set out. There was a warning of the risk of false negative results arising from the 'window-period' phenomenon of HIV infection. The need for counselling was emphasised.

**30.202** Copies of the booklet, and a 'dear doctor' letter to accompany it, were sent to CAMOs on 1 October 1985 for distribution.<sup>335</sup> The 'dear doctor' letter emphasised the essential elements in the proposals, the need for synchronous provision of alternative arrangements, the need for counselling and the need for very strict confidentiality.<sup>336</sup>

**30.203** The two booklets provided reasonably comprehensive information for GPs and other doctors likely to have to deal with the problems of AIDS.

### *Screening begins*

**30.204** Testing was introduced officially on 14 October 1985, although the SNBTS began testing donations before the official date. In the South East Scotland region testing began on 23 September 1985. There and throughout Scotland, all blood in stock (both the SNBTS stock and that already distributed throughout the NHS) was tested before the official start date.<sup>337</sup> McClelland explained to the Inquiry that testing began slightly early

<sup>333</sup> Ibid [SGH.002.7091] at 7095

<sup>334</sup> Scottish booklet – 'Acquired Immune Deficiency Syndrome – AIDS – Booklet 2 – Information For Doctors Concerning the Introduction of the HTLV III Antibody Test' [SGH.002.7081]

<sup>335</sup> Covering Letter [SGH.002.7079]

<sup>336</sup> Letter [SGH.002.7080]

<sup>337</sup> Dr McClelland – Day 50, pages 51–52; Letter from Professor Cash to Dr McIntyre, SHHD, dated 28 October 1985 [SNB.005.8091]

in this manner, in order that all blood in stock could be said to have been tested by 14 October 1985.<sup>338</sup>

**30.205** On 2 October 1985, the SNBTS Directors, with the exception of Dr Mitchell, who was ill, met.<sup>339</sup> All four regions represented had chosen the Wellcome test; the minutes do not record which test had been chosen in the West area.<sup>340</sup> It was noted that the Wellcome test might be subject to substantial variations between batches. Dr Mitchell was to evaluate the Abbott test in the West, subject to Dr Gunson supplying the material and DHSS authority being obtained. The BTS staff had attended counselling courses. At the PFC, all finished product and plasma was being screened.<sup>341</sup>

### *Post-screening surveillance*

**30.206** On 7 February 1986 there was a meeting at NIBSC on the Virological Aspects of the Safety of Blood Products.<sup>342</sup> The various test kits available and their performance were discussed, as was the experience of screening blood donations so far.<sup>343</sup> Thirteen donations out of more than 600,000 tested had been confirmed to be positive, an incidence of one in 46,000 donations, which was very low in international terms.<sup>344</sup>

**30.207** In a Parliamentary answer on 12 December 1986, Tony Newton, a junior Minister in the DHSS, said:

No cases of HIV transmission through blood transfusion have been reported since testing was introduced. Although there is as yet no corresponding test for new strains, there is no evidence from preliminary monitoring to suggest that these are prevalent in the United Kingdom. Thus there is no reason to believe that blood supplies are at risk from this source although we are keeping the matter under close review.<sup>345</sup>

**30.208** Mr Newton explained that the safety of the blood supply in the UK was maintained by (i) those who may have been exposed to known particular risks of infection being asked not to donate blood and (ii) testing of all donations.<sup>346</sup>

**30.209** The effectiveness of screening came into focus again in January 1987. On 5 January 1987 Miss P A Cox of the SHHD sent a note to the Minister of State and others including Dr Covell, commenting on press coverage of a leukaemia patient in Glasgow who was found to have HIV following a blood transfusion in August 1986.<sup>347</sup> Miss Cox said that the DHSS had been informed of the infected donation, that no Ministerial statement was recommended and that any further information should come from Professor Cash. The incident resulted from viral transmission from an HIV infected patient in the 'window' between infection and the appearance of antibodies in his blood.

<sup>338</sup> Dr McClelland – Day 50, pages 51–52

<sup>339</sup> Minutes [SGH.001.6412]

<sup>340</sup> As reflected in paragraph 30.210 below, the west area would select the Wellcome test also.

<sup>341</sup> Minutes [SGH.001.6412] at 6413–14

<sup>342</sup> Minutes [SNB.005.1495]

<sup>343</sup> *Ibid* [SNB.005.1495] at 1505

<sup>344</sup> AIDS Conference Newcastle – 11th–13th February 1986 [DHF.002.0816] at 0826

<sup>345</sup> *Hansard* extract [SGH.002.7370]

<sup>346</sup> *Ibid* [SGH.002.7370]

<sup>347</sup> Note [SGF.001.1246]

**30.210** Although the data extend beyond the current period, it is worth noting at this stage that the Wellcome HIV test became very effective after its initial teething troubles.<sup>348</sup> In the period from October 1985 to about the end of 1986, 176,149 tests were carried out by West of Scotland BTS on donations in their area using the Wellcome test. The results were:

**Table 30.1: Donations referred for confirmation by West of Scotland BTS**

Number of Donations Tested	176,149	Oct 1985-end 1986
Initial Screen Positive (Manufacturer's Protocol)	73	0.040%
Repeat Reactive	31	0.017%
Confirmed HIV-positive	6	0.003%

**30.211** Twenty-five of the 31 repeat reactive results were false positives. Data on use of the HIV tests on blood donors since 1986 showed that around 99% of repeat reactivities were false positives. During the first few months of testing, the Abbott HIV test was used sporadically (with fewer than 5000 tests used). In the West of Scotland, the Abbott test proved less specific than the Wellcome test: around 30 repeat reactive samples (all false) were referred after testing for a short period of time.<sup>349</sup>

## Discussion

### *The need for local evaluation of US pharmaceutical companies test systems*

**30.212** As noted above, concern grew in 1985 that the UK evaluation exercise was delaying progress and some haemophilia experts proposed that at least one US test system should be introduced without full evaluation having been completed. In the event, however, no witness at the Inquiry's Oral Hearings or in providing a written statement disputed the necessity of an evaluation exercise. Professor Cash,<sup>350</sup> Dr McClelland,<sup>351</sup> Dr Mitchell,<sup>352</sup> Dr Scott<sup>353</sup> and Dr Iain Macdonald<sup>354</sup> (DCMOs for Scotland) and Dr Archibald McIntyre (SHHD)<sup>355</sup> all considered that it was necessary to assess how kits, developed in another part of the world, functioned when used to test donors in the UK. As set out in paragraph 30.45, it was recognised internationally that it was for each country to assess the risk AIDS posed to its population and to establish, among other things, appropriate testing systems. Local evaluation was clearly justified.

**30.213** There was contemporaneous material illustrating the commitment to evaluation. Professor Zuckerman in January 1985 supported the introduction of US tests as soon as practicable but not before his own studies were complete: a clear practical demonstration of the principle that there should be local evaluation before the use of the tests in practice. Similarly, Professor Bloom was an enthusiastic supporter of the introduction of US tests

<sup>348</sup> Dr Dow's Witness Statement [PEN.017.1680] at 1684

<sup>349</sup> Ibid [PEN.017.1680] at 1684

<sup>350</sup> Professor Cash – Day 48, pages 43–44 and 130 – to buy a kit and start testing would be 'ethically unacceptable'. See also Professor Cash's letter of 12 February 1985 to the CMO [SNB.013.2233] – most of the emerging commercial kits seemed to have a false positivity rate which was 'embarrassingly high'.

<sup>351</sup> Day 50, page 39

<sup>352</sup> Day 51, pages 55–56

<sup>353</sup> Day 49, page 102

<sup>354</sup> Dr Macdonald's Statement [PEN.017.0559] at 0561

<sup>355</sup> Day 51, pages 58–59; Dr McIntyre's statement [PEN.017.0552]

in the early part of the year but, on 9 July 1985 at a meeting of the Central Committee for Research and Development in Blood Transfusion, acknowledged the need for a proper evaluation of the tests. The Chairman, Dr Gunson, expressed the view that until a proper evaluation of the available tests had been carried out within the PHLS and the BTS the tests should not be used for routine screening of blood donations.<sup>356</sup>

**30.214** The risk of false positive results in the routine use of the available US test systems was a significant issue at least until August 1985.<sup>357</sup> This was a substantial issue affecting donors and the blood transfusion services. In addition, the deficiencies in the US test kits (in particular the lack of uniformity and comparability among the several manufacturers' tests due to inconsistencies in the test sera provided) undermined the reliability of the results. It would not have been responsible to have introduced test kits manufactured in the US without evaluation in the UK.

**30.215** Most other experts were consistently in favour of evaluation. The EAGA ad hoc Expert Working Group was set up to design and possibly oversee the technical evaluation project. Professor Tedder commented that field trials were required and he expected the MH/CB assay to be subjected to evaluation. On the evidence as a whole, evaluation was clearly a necessary step to provide assurance of the acceptability of any test for application in the UK and in Scotland in particular. Timing, and in particular whether the process became excessively protracted, remains a contentious issue.

#### *The timing of an evaluation exercise*

**30.216** It seems clear that, in the circumstances of the development of HIV test kits, the evaluation of any given test kit, whether by a regulatory body or by the manufacturer, involved at least two stages: (i) the progressive testing of prototypes until the manufacturer was in a position to proceed to full-scale marketing and (ii) the validation of the kit supplied for routine application as conforming to the specification and level of performance developed by prototype testing. Marketing would be impossible without the conventional set of claims having been exposed to evaluation and found to be consistent with the evaluation results. However, the issue whether to proceed to marketing was squarely one for the manufacturers. There was no regulatory control in the UK, though manufacturers had a clear indication of the likely attitude of the UK health authorities. The letter of 21 January 1985 sent to producers intimated that information would be required at the evaluation stage to substantiate claims made for the product.<sup>358</sup> The views of the health departments would be likely to affect market perceptions. There was no obstacle, however, to submitting kits for evaluation: Abbott were able to do so before they were able to meet market demand in the autumn of 1985. What was required was enough material to meet the requirements of the body carrying out the evaluation. Abbott duly began the process.

**30.217** Although not selected for the second stage UK evaluation exercise, Abbott was originally the principal candidate as supplier of US systems in Scotland. The West of Scotland BTS in particular had a long association with the company. In the period following the general introduction of testing, using the selected Organon and Wellcome test systems, Abbott kits were obtained to carry out the continuing evaluation of that system in comparison with Wellcome's system. It appears to be a reasonable inference

<sup>356</sup> Minutes [PEN.016.1142] at 1145

<sup>357</sup> When, approximately, the second generation Abbott and Organon tests, which were probably better than the original kits, became available.

<sup>358</sup> A copy of one such letter is [DHF.001.9140]

from what happened in fact that obtaining an alternative supply of US test kits in Scotland would have depended on Abbott, at least in 1985, when the choice of system was a live issue. As indicated in paragraphs 30.151–30.153, Dr Dow’s ‘mini-evaluation’ of the Organon and Wellcome test systems favoured Wellcome’s and, as between Wellcome’s kit and Abbott, the Abbott kit proved less specific than the Wellcome kit.

**30.218** Lack of specificity had been the issue with Abbott’s test kit since the company had entered into arrangements with British evaluators in February 1985 to carry out clinical trials of small quantities of the Abbott HTLV-III EIA Diagnostic test kit at the Regional Virus Laboratory at Ruchill, the North London Blood Transfusion Centre, Edgware, and Middlesex Hospital.<sup>359</sup> Dr Dow obtained Abbott kits for evaluation in the spring of 1985. If the company had obtained the support it sought from these contractual trials, there was no regulatory impediment to their introduction in the UK market. The company was unable to satisfy the FDA until March 1985 that the kit should be licensed in the US and it was found that there were problems of poor specificity with the first kits supplied for evaluation in Scotland.<sup>360</sup>

**30.219** It is apparent that Abbott’s problems had not been resolved when Dr Dow’s mini-evaluation began and had still not been finally resolved when Wellcome’s Wellcozyme test emerged as the favoured test system. As Dr Dow commented, the Wellcozyme test was British, appeared to be more robust and was user-friendly.<sup>361</sup> It was demonstrated by the evidence that evaluation of available US pharmaceutical companies’ kits from the spring of 1985 showed an unacceptable lack of specificity and that, when improved Abbott kits became available for comparison with the Organon and Wellcome test systems, the original problems had not been resolved so as to be competitive. In the circumstances, timing of the evaluation of imported kits is not a live issue. By the time acceptable kits became available, Wellcozyme was proven in evaluation.

### *Priorities in risk assessment in the United States*

**30.220** Policy makers and transfusion practitioners in the UK emphasised the need to protect donors from risks associated with test system that produced high percentages of false positive results. The comparative positions in the United Kingdom and the United States of America have been set out in paragraphs 30.41–30.47 in discussing the need for local evaluation of imported products. As noted in those paragraphs, it had been commented as early as 1985 in the paper *Blood Policy and Technology* (paragraphs 30.12–30.17) that the US approach subordinated the interests of donors to those of recipients, a position unacceptable in a public sector transfusion service.

### *Timing of routine screening*

**30.221** Specificity was a substantial issue affecting donors and the blood transfusion organisation and resolving it was critical to progress towards routine screening. There were, however, other factors that required time to deal with.

**30.222** Dr Dow discussed the practical issues that arose from the introduction of ELISA testing.<sup>362</sup> Completely new washing and reading equipment was required. A spectrophotometer was required. Trained staff, working space, pipetting equipment,

<sup>359</sup> Letter from Abbott to DHSS dated 11 February 1985 [DHF.001.9169]

<sup>360</sup> Dr Dow’s Witness Statement [PEN.017.1680]

<sup>361</sup> Ibid [PEN.017.1680]

<sup>362</sup> Ibid [PEN.017.1680] at 1681–82

timers and incubators were required to perform the tests. Staff had been accustomed to RIA technology (in Scotland largely through use of Abbott Diagnostics Ausria-II HBsAg test) since 1975 and the introduction of ELISA technology required re-training. Similar considerations had been behind the NBTS preference for RIA technology at the early stages of development of the MH/CB assay. It is difficult for the Inquiry to put a value on the work involved in carrying the changes into effect but the impression given was that it was not inconsiderable. On any view it was a factor that had to be dealt with relative to the test system selected for routine use. The preparations were set out in Professor Cash's letter dated 2 August 1985 (paragraph 30.187). The work was put in hand and there is no basis in the evidence for criticism of the rate of progress thereafter towards full implementation of routine screening.

### **Availability of US test kits in 1985**

**30.223** In the circumstances, the ability of commercial companies to supply the needs of the UK, and in particular Scotland, for test kits for routine use is a secondary matter, although it is not wholly irrelevant. Abbott's intention to supply the European demand from Delkenheim, Germany was delayed: their factory there did not begin to supply kits until the autumn of 1985. Abbott's test appears to have been approved for use in France on 24 July 1985.<sup>363</sup> How the official position evolved in France is unclear.<sup>364</sup> A WHO publication indicates that a 'surveillance scheme' was commenced there in July 1985.<sup>365</sup> While that was in progress, routine screening for antibodies to HIV was officially implemented in August 1985.<sup>366</sup> It appears that approval for use of the Abbott kit was granted before surveillance was begun and before routine screening became official policy. Whatever the regulatory position, it appears to be clear that, from approval in July 1985 until Delkenheim began production, Abbott could only have supplied France from Chicago and that Chicago did not have enough kits to satisfy domestic demand until mid-July 1985.<sup>367</sup> To provide kits for France, Abbott had to modify its method of cloning H-9. That was achieved in mid-July 1985 and supplies to France began a week later.<sup>368</sup> It is not possible to form a view whether Abbott could have supplied the UK, and Scotland in particular, on a commercial basis before the opening of Delkenheim but it is reasonably clear that supplies could not have come on-line before late July 1985 and only then if they could have been shipped from Chicago at that time.

**30.224** Dr Dow's evidence is conclusive as to availability of Abbott kits in Scotland from about July 1985. His mini-evaluation in July 1985 was restricted by the shortage of supplies of kits for evaluation. Fewer than 5000 kits were supplied for the continuing evaluation of Abbott's system until the selection of Wellcome's system was finally decided in West of Scotland. On the evidence available to the Inquiry, there was not a sufficient supply of Abbott kits to suggest that the company could have met Scottish market demand for general use for screening of blood for transfusion before the first phase of evaluation was complete.

<sup>363</sup> Crewdson, J. *Science Fictions* [PEN.017.1057] at 1067

<sup>364</sup> *Ibid* [PEN.017.1057] at 1066–67

<sup>366</sup> The evidence of Professor Cash – Day 48, page 185 – that routine screening was introduced in France in about May 1985 appears to have been wrong.

<sup>367</sup> Crewdson, J. *Science Fictions* [PEN.017.1057] at 1068

<sup>368</sup> *Ibid* [PEN.017.1057] at 1067

*Delay caused by or contributed to by administrative decisions***The United Kingdom position**

**30.225** In an Inquiry such as this it was inevitable that there would be questions as to whether the administrative process caused or contributed to delay in the implementation of routine screening for HIV. The resolution of issues surrounding the decisions of UK Ministers and Departments relative to the use of test kits in England and Wales is not within the competence of this Inquiry. It is not a 'Scottish matter', a matter that relates to Scotland and is not a reserved matter. In addition, at a practical level, decisions taken in England could not have been investigated fully in the absence of representation of the Department of Health. Dr Smithies, a central figure over the material period, did not feel able to assist the Inquiry.<sup>369</sup> It appears, further, that either not all of the discussions at the time were recorded or the Inquiry does not have all of the relevant records (paragraph 30.103).

**30.226** That apart, it is clear that, at the time, the introduction of HIV testing was not treated as a UK policy issue. Dr Scott's minute of 8 February 1985 (paragraph 30.167) expressed regret that a policy decision on testing had not been taken at a UK level. Whether his regret was appropriate is immaterial: the minute reflected the reality that Scottish transfusion policy on this matter was the sole responsibility of Scottish Ministers and their SHHD advisers.

**The Scottish position**

**30.227** Before discussing the role of Scottish officials and Ministers, it is important to recall the overall time-frame for the critical discussions and decisions. The announcement of the isolation of HTLV-III by Dr Gallo's team, and their prototype ELISA to screen blood, on 23 April 1984, included Ms Heckler's prediction that a test to screen the blood supply with 100% certainty would become widely available within six months. There was, in fact, no test available for marketing until early March 1985. Continuing problems with lack of specificity postponed the date at which an effective screening test was available from Abbott until late July 1985 (if one accepts the approval of the kit by French authorities on 24 July as a reliable indicator that the test had achieved a level of specificity acceptable to France). The MH/CB research test was in use from 4 July 1984 and the Cheingsong-Popov article on 1 September 1984 showed that the test was highly specific: there were almost no false positives. Following scale-up, and the resolution of production problems, the CAMR Porton antigen came on-line in late spring 1985. The MH/CB project was not government controlled: it was a private sector commercial project. Kits were in Dr Dow's hands for testing in July/August 1985.

**30.228** Progress in developing test kits, in the USA and in England, was rapid. In England, it was driven by Professor Weiss and Professor Tedder. The UK Government was informed of progress, albeit to a limited extent. The scope for Scottish Government agencies to influence the rate of development was limited. Realistically, it was in the hands of those with commercial interests in the success of their products.

**30.229** However, whether or not to introduce screening in Scotland was plainly a Scottish matter. The SHHD elected to follow the lead of the DHSS in relation to evaluation. A joint approach to resolving issues relating to the introduction of screening is not obviously inappropriate. A number of specifically Scottish issues arise, however:

<sup>369</sup> Response from Patrick Hennessy at the Department of Health (on behalf of Dr Alison Smithies) dated 01 April 2011 [PEN.017.0504]

- Whether Scottish officials and advisers were fully integrated into the process so as to be able to represent Scottish interests and positions.
- Whether the information Scottish officials and advisers had was adequate to enable them to assess Scottish interests.
- Whether factors that materially affected the process were of equal weight throughout the UK, or differed in weight so that a separate outcome for Scottish practice would have been possible or appropriate.
- Whether purely Scottish factors could or should have resulted in earlier introduction of screening in Scotland than in the rest of the UK.

### Participation of Scottish officials and experts

**30.230** From a purely Scottish point of view, specifically the view of the SNBTS, it was unfortunate that the very experienced team at the West of Scotland BTS did not have the opportunity to participate in the initial field tests of kits proposed at the meeting on 28 June 1984 referred to in Dr McClelland's oral evidence. It was envisaged that the results would influence practice throughout the UK. There is nothing to indicate, however, that if they had participated the outcome would have been different and Scottish experts were involved in oversight of the process.

**30.231** From early 1985, the EAGA was the most influential advisory group dealing with matters relating to HIV/AIDS. Professor Cash and Dr McClelland were members and Dr McClelland was also a member of the sub-group set up to consider screening tests. Dr McClelland was an active contributor to the work of EAGA and its sub-group. He and Dr Gunson were responsible for the design of the programme for the evaluation of test kits. The discussion and amendment of the proposals at the meeting of the sub-group on 1 March 1985 supported a laboratory assessment of the kits followed by a large scale field assessment. The scale of the main evaluation (10,000 specimens) and the sub-division of specimens into aliquots sufficient to ensure that all kits could be tested at the PHLS, leaving sufficient specimens for evaluation tests in the proposed second phase of the exercise, were developed in discussion to which Dr McClelland was party.<sup>370</sup>

**30.232** Professor Cash was critical of the approach adopted by the DHSS to the evaluation programme, in his written statement and in the course of his oral evidence.<sup>371</sup> Professor Cash's comments do not help to answer the question whether the information Scottish officials and advisers had was adequate to enable them to assess Scottish interests. Apart from other considerations, he accepted that there were never enough test kits available to do what he wanted, a fact which he came to appreciate.<sup>372</sup>

**30.233** That there were limited supplies of test kits was clear from the evidence of Dr Mitchell and Dr Dow. Dr Dow's work was directly affected. Much of Professor Cash's argument about the relative efficiency of a NBTS/SNBTS evaluation fails in light of the evidence about supplies.

---

<sup>370</sup> Meeting minutes [SNB.001.0172] at 0172-73

<sup>371</sup> Professor Cash's Witness Statement [PEN.017.1038] at 1041

<sup>372</sup> Professor Cash – Day 48, page 43. See footnote 215 of this chapter, above.

**30.234** The first phase of the evaluation, involving 220 samples, seems to have taken about four to four and a half months to the end of July 1985<sup>373</sup> and the extensive field study stage was never carried out as an integrated exercise. There was an extensive evaluation in Manchester and Edgware and other transfusion centres carried out tests to inform the selection of kits. There is a need to consider whether there were factors relevant to Scotland that indicated that Scotland could and should have taken an independent approach. There may have been factors that materially affected the process that were not of equal weight throughout the UK, or differed in weight so that a separate outcome for Scottish practice would have been appropriate.

**30.235** The possibility of a Scottish evaluation exercise was mooted at the start of 1985. The Scottish Transfusion Directors decided to take action themselves. Professor Cash intimated the decision to all Scottish RTDs and to Dr Bell.<sup>374</sup> There was a clear will at that stage to proceed independently in Scotland.

**30.236** That proposal was stopped by Dr McIntyre, SHHD and by the discussions that followed his intervention. Professor Cash's evidence was clearly to the effect that the proposed Scottish evaluation in West of Scotland could have led to earlier screening in Scotland. From the evidence of Dr Dow and Dr Mitchell, however, it appears that there would have been problems in obtaining kits in sufficient numbers to carry out an evaluation of the scale required to provide reliable data, as already noted. Not only would it have been necessary to get access to all of the relevant US kits, it would have been necessary to have access to the MH/CB assay. Professor Weiss, Professor Tedder and Wellcome all had interests in aspects of that assay as developed for further use. Scottish attempts to become involved in work with Professor Weiss and Professor Tedder were not successful. It is not apparent how access to their material could have been obtained otherwise. Without that, any Scottish evaluation would have been seriously deficient. In the event, the proposal was probably stopped to maintain the concord with the UK Department of Health. However, in substance, without satisfactory evidence that an evaluation of appropriate scale could have been undertaken, all that one is left with is Dr Mitchell's evidence that West of Scotland was well placed to do the work in terms of skill and experience and that pride was hurt by being denied the opportunity.

**30.237** There is a theoretical possibility that, had there been an independent Scottish evaluation and had it produced reliable findings, cases of infection might have been prevented. The necessary hypothesis for that, however, includes so many elements that the possibility becomes vanishingly small as they are applied sequentially. Scotland did not have the necessary containment facilities. Timing is an issue; the availability of test kits to complete the project is an issue; availability of commercial kits on the market to meet the demand of the treating centre is an issue; and the risk of false negatives compounds the difficulties as a whole. Further, the wide range of issues around dealing with donors had not been addressed, in the UK as a whole or in Scotland in particular, by this time. So far as the SNBTS was concerned, the need for decisions on these matters had been identified in Dr McClelland's paper of 15 May 1985. It was necessary for these issues to be dealt with before screening began. Professor Cash's view that routine screening could have been introduced earlier in Scotland than in the United Kingdom as a whole is not supported by the evidence as a whole. It is also difficult to reconcile with the views of Dr McClelland and Dr Mitchell.

---

<sup>373</sup> Discussion with Professor Cash left the period uncertain – Day 48, pages 104–105.

<sup>374</sup> Letter to Dr Mitchell copied to Transfusion Directors and Dr Bell [SNB.005.9713]

**Concern about delay**

**30.238** It was evident to the Inquiry that, from the beginning of 1985, there was anxiety about when testing of donated blood for the AIDS virus would be introduced in the UK. Haemophilia doctors, and Professor Bloom in particular, were anxious that US test kits should be introduced as soon as they became available. His letter of 31 May 1985 put concern for haemophilia patients and patients undergoing surgery above other interests, including those of donors, and proposed that re-testing and confirmatory testing and donor counselling should be left over to be dealt with as separate issues.<sup>375</sup> Professor Bloom's concern at the delay, as he saw it, is understandable: he represented a particular and specific interest. The same can be said of the letter sent by Professor Bloom, Dr Forbes and Dr Rizza to the *BMJ* in June 1985 to advocate the rapid introduction of screening for HTLV-III antibody of all blood donations, particularly since three commercial test kits had been approved by the FDA by that date. It also referred to the risk to patients with haemophilia of using cryoprecipitate or unheated blood products and also to the risk to patients undergoing blood transfusion.<sup>376</sup>

**30.239** Although the June 1985 letter was said to be written on behalf of the Haemophilia Reference Centre Directors throughout the UK, the situation for patients with haemophilia in England and Wales was more difficult than in Scotland at that time. NHS heat-treated Factor VIII and Factor IX products were not in routine issue in England and Wales and the only heat-treated products available were commercial. Patients in Scotland had the benefit of heat-treated Factor VIII products produced by the PFC from December 1984 and would have heat-treated Factor IX from October 1985.

**30.240** On the other side of the debate, transfusion doctors had concerns about whether the tests being developed in the USA were sensitive and specific enough for large-scale screening in the UK. Again, the topic was discussed in terms of the whole of the UK. Professor Cash raised some of these issues in his letter to *The Lancet* published in March 1985 and signed by all of the Scottish Regional Directors and most of the English Reference Centre Directors.<sup>377</sup> It recorded the authors' belief that commercial testing kits were likely to give high rates of false positive results. They contended that careful consideration should therefore be given before such kits were introduced for the screening of blood donors in the UK, both for the benefit of the blood supply and for the sake of the donors themselves. The contemporaneous letter from physicians in California also highlighted the danger of missing positive samples if the cut-off value for a positive sample was set too high.<sup>378</sup> The views of the Transfusion Directors were strongly expressed and, in view of the differing policy positions adopted at the time in the US, presented a more acceptable position for the UK in general, and Scotland in particular, relative to the need for evaluation.

**30.241** The March 1985 letter represented Professor Cash's point of view at the time. That view was also reflected in his unpublished response to the letter sent by Professor Bloom, Dr Forbes and Dr Rizza, published in the *BMJ* in June 1985.

<sup>375</sup> Letter from Professor Bloom to DHSS re: introduction of FDA-approved tests [DHF.002.5510]

<sup>376</sup> Bloom et al, 'HTLV-III Haemophilia and Blood Transfusion', *British Medical Journal*, 22 June 1985 [LIT.001.0333]

<sup>377</sup> Ala et al, 'HTLV-III Antibody in Sequential Plasma Samples from Haemophiliacs 1974-84', *The Lancet*, 2 March 1985 [LIT.001.0374] at 0375

<sup>378</sup> Carlson et al 'HTLV-III Antibody Screening of Blood Bank Donors', *The Lancet*, 2 March 1985 [LIT.001.0374]

**30.242** Professor Cash's evidence on these matters suggests that in his view, at mid-1985, the introduction of testing should have been postponed. There may be some attraction in the argument: in an ideal world one would cross all the 't's and dot all the 'i's before proceeding. That would have added to delay, however, and it is inconceivable that such a suggestion would have been acceptable against the background of growing pressure for testing to be introduced.

*Abandoning the second phase of evaluation*

**30.243** Pressure to introduce screening increased over the summer of 1985. The events are set out in the Preliminary Report at paragraphs 8.130–133 and in the paragraphs above. The Transfusion Directors themselves, in their Working Party advising on screening, concluded that the evaluation of the kits in the Blood Transfusion Service should take place but that it was not possible to complete that evaluation prior to arrangements being undertaken for the introduction of screening.<sup>379</sup>

**30.244** The second phase, which was the field study in transfusion centres, was truncated and information about it does not appear to have been available to Directors when they made their final preparations for screening, including their choice of kits. So, all that was available was the information from the first phase, which (as far as blood donors were concerned) only involved 220 samples.

**30.245** The evidence of Professor Cash, Dr Mitchell and Dr McClelland, though differently expressed, was to the effect that the second phase was an important element in the evaluation process and that abandonment of it weakened its reliability. That must be so, if the original decision was valid and more than a laboratory test with local evaluation was required for confidence in the selected test systems.

**30.246** However, the exercise that took most time, and was the principal cause of any potentially unacceptable delay that may have occurred, was the CAMR laboratory process. The perception of EAGA at the time (as expressed by the Chairman, Dr Acheson) was that the exercise had been carried out with expedition.<sup>380</sup> Professor Cash and Dr McClelland were both present at the EAGA meeting on 30 July 1985, as was Dr Covell. This was an important meeting concerned with progress towards the local evaluation of the two selected kits, among other topics. The Inquiry has not uncovered contemporaneous evidence of complaints that the CAMR exercise had not been carried out with the speed appropriate for a virological evaluation of the sensitivity required. Professor Tedder was also at the meeting on 30 July 1985. He had an opportunity to protest if progress with the production contract had been affected by delay caused by the Phase 1 evaluation. From the minute of the meeting it is not possible to identify any critical comment relating to the time taken.

**30.247** If the first phase of the exercise was required in any event, local evaluation, whether a requirement of the original specification or not, would have followed. There was no unnecessary delay in Scotland and no delay overall. Whether a different approach, perhaps involving virologists with transfusion expertise, as advocated by Professor Cash, could have been carried out more expeditiously involves considerable speculation as to who would have been engaged, how much time would have been required and whether the exercise would have succeeded. In his letter to Professor Cash dated 7 August 1984,

---

<sup>379</sup> First Version of Report [SNB.001.0357] plus corrigendum [DHF.001.7532]

<sup>380</sup> Minutes of Meeting [SNB.001.0432] at 0434

Dr McClelland noted one significant problem: it was highly unlikely that there was a facility in Scotland that could have undertaken the work of producing significant quantities of HIV antigen.<sup>381</sup>

**30.248** Further, the change of direction does seem explicable. In January 1985 it was probably not anticipated that the first phase of evaluation would take the four to four and a half months it did and by the summer the landscape was different: new 'editions' of the tests were coming on-line with assured increased effectiveness. Screening had become even more urgent and the idea of completing and reporting on the field evaluation had to be abandoned.

**30.249** So, in short, it appears not unreasonable to have decided in January 1985 to assess all available kits in an attempt to guide transfusion services as to which to purchase. Even if it was unreasonable, the alternative of simply buying whatever US kits could be obtained as soon as they were available and starting with them would have led to other problems. If it had been decided to take that alternative approach, a sufficient supply of test kits would not have been available until the end of July 1985. Further, the false positive issue would not have been avoided.

**30.250** More significant, perhaps, is to consider what would have happened had the UK simply begun routine testing as soon as Abbott kits were licensed in the United States and were available for marketing abroad. This would have been after late July 1985 at the earliest. Undoubtedly, if they had been first generation kits, similar sorts of problems to those which occurred in the US would have ensued, given the problems with the H9 cell line discussed above. The alternative policy, of awaiting the development of improved kits before acting, would have been open to serious criticism: until improved kits were actually developed and tested, it would have required an article of faith to promote a testing strategy on the hypothesis that they would necessarily appear.

**30.251** The Inquiry has not found reliable evidence of (i) what happened with the Electro-Nucleonics kit, which was assessed in the UK evaluation and which was approved in the US only days after Abbott, or (ii) what kits were used in the other countries which started screening early, such as Australia. There cannot have been insurmountable supply problems in these other countries unless they had developed their own test systems. Even if the Electro-Nucleonics kit had been available and used in the UK, however, it would also have suffered from the 'H9 problem' and therefore liability to false positive results, because it too was manufactured from the HTLV-III<sub>B</sub> isolate.

### *Other questions*

**30.252** One further question is material: the necessity for kits to have the approval of the FDA for use in the USA before introducing them for screening of blood in Scotland. Dr Lane suggested in July 1985 that this was necessary for BTS marketing purposes. That would not have been relevant in Scotland, however, as, in terms of the chronology set out, the FDA approval was granted before any kits were introduced for screening in Scotland. More generally, the decision that local evaluation was necessary implied that the FDA approval was not conclusive of the suitability of kits for screening in Scotland or the UK more generally.

---

<sup>381</sup> Dr McClelland's letter to Professor Cash [SNB.006.5977]

**30.253** Further, it was considered that, as Dr Smithies put it, such a stipulation might not act in Wellcome's interests. It would not have been in the best interests of any UK manufacturer to have imposed on top of the requirements of UK evaluation a requirement to satisfy the FDA under a regulatory system that had no direct applicability in the UK. On any view that would have exposed the domestic product to two separate evaluation processes and, in the case of the FDA's procedures, at least a risk of significant delay.

**30.254** In addition, there were serious concerns about the US process that had been applied in 1985 in evaluating the systems for use in the US, in particular about the provision of different sera samples to each manufacturer, undermining the comparisons that could usefully be made among test results. It would not have been possible to be confident that the FDA's assessment of any UK-produced test system would have been on an equal basis with the earlier exercise: there was no reference panel of samples against which to test that.

**30.255** In short, subjecting UK products to a need for approval of the FDA before introducing them for use in Scotland would not have been a rational exercise of judgment by any UK or Scottish Government agency.

## Conclusions

**30.256** The production of screening tests for antibodies to HIV in 1984 and 1985 involved research and development work, in the USA, in France and in England, that was carried out with remarkable expedition and commendable success.

**30.257** In the UK generally, and in Scotland in particular, the role of government agencies in relation to HIV research is best understood as that of interested spectators as private sector institutions proceeded to build on earlier research in investigating human retroviruses and to develop (i) an independent British HIV isolate and (ii) a unique anti-HIV assay, conceptually distinct from US models, using proprietary systems and methodology which were commercially confidential generally and in part protected by patents.

**30.258** Suggestions that UK BTS researchers, and in particular SNBTS researchers, could have made more rapid progress with evaluation of an acceptable assay than was achieved by private sector researchers are without foundation. Scotland, in particular, had no laboratory with containment facilities sufficient for the safe handling of live HIV and, in addition, the MH/CB assay was proprietary and information about it was not made available to Scottish scientists when it was requested. The DHSS-sponsored first phase evaluation was the best public sector process available. If progress had depended on the public sector bodies involved, the criticism of the patient core participants that they represented 'a startlingly diverse and unstructured collection'<sup>382</sup> might have been relevant, though variety is not necessarily adverse to progress. The criticism is, however, without substance.

**30.259** Progress towards implementation of screening was not inhibited by the involvement of government agencies, largely because those who had commercial interests to promote pursued solutions independently and succeeded in producing marketable products on a commercial basis that enabled policies on the introduction of screening to be implemented as soon as was practicable.

---

<sup>382</sup> Closing Submission – Patient interests [PEN.019.0552] at 0555

**30.260** The UK Government had an interest in the development of a UK test which government agencies were keen to promote. This could have delayed implementation of routine screening if imported products of acceptable quality had been available in appropriate quantities to meet UK market demand before British commercial products were available. In the event that did not happen. Though truncated in the end, the evaluation programmes applied equally to all manufacturers.

**30.261** By the date of implementation of routine screening, imported products had not matched British commercial products in terms of specificity.

**30.262** There is no legitimate ground for criticism of the processes adopted for the introduction of anti-HIV screening that can be founded on delay. It was achieved as soon as was reasonably practicable. In any evaluation exercise, carried out in such circumstances, a tension is likely to exist between the exigencies of full scientific rigour and the need for progress.

## CHAPTER 31

### THE INTRODUCTION OF SCREENING OF DONATED BLOOD FOR HEPATITIS C

#### Introduction

**31.1** This chapter concerns the introduction of screening for antibodies to the Hepatitis C virus (HCV) in the blood donor population in Scotland. It will follow the progress towards and up to the introduction of UK-wide screening on 1 September 1991.

**31.2** The relevant period began when the Chiron Corporation of California announced in May 1988 that it had isolated and cloned a protein of the blood-borne non-A, non-B Hepatitis (NANB Hepatitis) virus. At the same time, Chiron was working to develop and release tests to detect antibodies to the virus, which in time became known, as the Hepatitis C virus. First generation tests were made available to other parties from 1989. The availability of antibody test kits opened the way for scientists such as virologists and transfusionists to assess and try to understand the tests and to gauge their value and usefulness in screening blood donations quickly, effectively and accurately, and counselling potentially large numbers of donors. Developing knowledge provided policy makers and their advisers, at government and institutional levels, with information required to formulate and implement policies on the introduction of screening. This chapter will discuss the chronological development of government policy by examining the work of the government's in-house advisers and independent advisory committees.

**31.3** The introduction of screening for antibodies to HCV (anti-HCV) was initially examined in Chapter 9 of the Preliminary Report in paragraphs 9.87 to 9.291. Since that section was written, the Inquiry has examined more written documentation on this topic and gathered more information on the background to screening, as well as heard a great deal of oral evidence. This chapter will therefore set out a fuller and more focused account of the introduction of screening than was possible in the Preliminary Report.

#### Hearings of evidence

**31.4** The interval between the availability of tests for the Hepatitis C virus in 1989 and the introduction of screening of donated blood for the virus in the United Kingdom in September 1991 was identified as a topic requiring to be considered at the Oral Hearings of the Inquiry.

**31.5** All the witnesses who gave evidence to the Inquiry on the topic, in writing or at Oral Hearings, were asked to consider a standard list of questions.<sup>1</sup> The standard list of questions was accompanied by an 'extended narrative'. This consisted of the paragraphs of the Preliminary Report from 9.247 to 9.283, with insertions to reflect material discovered after publication of that report.<sup>2</sup>

#### Chiron's breakthrough in May 1988

**31.6** The factual background to Chiron's discovery, and its role in defining the aetiology of Hepatitis C, are narrated in Chapter 16, *Knowledge of Viral Hepatitis 3 – 1986 Onwards*. In the initial announcement of the discovery on 10 May 1988, it was stated that Chiron had

---

<sup>1</sup> Schedule of questions for witnesses [PEN.017.2159]

<sup>2</sup> Extended narrative [PEN.017.2165]

developed a prototype immunoassay that might lead to a screening test for non-A, non-B Hepatitis virus antibodies.<sup>3</sup> In this chapter there is further discussion of the development and marketing of Chiron's assay, but it is appropriate first to set the scene with a brief summary of the developing picture.

**31.7** Chiron claimed that its research team had discovered 'a long-sought blood-borne hepatitis non-A non-B virus', not *the* virus that caused NANB Hepatitis, implicitly acknowledging the understanding at that time that there might be other causes of NANB Hepatitis. The development of immuno-diagnostic products for screening for NANB Hepatitis antibodies was advertised as a possibility, though it was emphasised that Ortho Diagnostic Systems, a subsidiary of Johnson & Johnson, would market any products which were developed.<sup>4</sup> The proprietary claims for intellectual property rights in and derived from the discovery were intimated at the outset. Some parts of the press release were more concerned with marketing than scientific accuracy.<sup>5</sup> Typically, the information published was less than explicit in disclosing the science underlying the discovery.

**31.8** The Chiron research team had not isolated and cloned the whole virus. Later research would show that the significant entity that had been identified, and specifically targeted by the tests tentatively announced by Chiron at this stage, was limited to one of the proteins of the virus, identified as the NS4 protein.<sup>6</sup> Not all genetic types of HCV have NS4 proteins. Limitations on the usefulness of a potential Ortho test related to this characteristic were noted as discussion of the adoption of the test progressed, and would emerge in practice when it first became available. In the meantime, however, Chiron's press release was optimistic in tone and the claim of the effectiveness of the proposed test was broad.

**31.9** In explaining briefly how the test would be used, the press release stated:

[B]lood banks will be able to apply a relatively simple assay procedure, using a plate coated with the virus protein, to screen for blood infected with hepatitis non-A, non-B virus. Antibodies from the infected blood bind to the plate, which is then rinsed – if the antibodies are present, a second coating of indicator antibodies will signal a color.<sup>7</sup>

**31.10** Just over a week after the initial announcement, on 19 May 1988, a shorter article containing similar information appeared in the journal *Nature*.<sup>8</sup> The journalist who wrote the piece in *Nature* appears to have drawn on the Chiron press release as source material.

**31.11** The announcement of the Chiron research was repeated in the journal of the American Association of Blood Banks (AABB), *Blood Bank Week*, dated 13 May 1988.<sup>9</sup> The comments published were cautious, reflecting a degree of scepticism in the absence of scientific details.

<sup>5</sup> Dr Dow – Day 67, page 87

<sup>6</sup> Chapter 16, *Knowledge of Viral Hepatitis 3 – 1986 Onwards*, paragraph 16.31

<sup>7</sup> Chiron press release [PEN.016.0290] at 0292

<sup>8</sup> 'Candidate cause identified of non-A, non-B hepatitis', *Nature*, Vol 133, 19 May 1988 [SGH.002.8036]

<sup>9</sup> See Chapter 16, *Knowledge of Viral Hepatitis 3 – 1986 Onwards*, paragraph 16.18

**31.12** The *Blood Bank Week* article gave further details of the test kit that was in development:

Chiron Corp. of Emeryville, CA, is submitting a screening test (ELISA) to detect antibodies to the viral particles, to the Food and Drug Administration for approval. The test, if approved, could prevent patients from receiving infected blood and help reduce the amount of blood discarded, possibly eliminating the need for the surrogate tests currently used, ALT and anti-HBc.<sup>10</sup>

**31.13** This information indicated a change of direction. Dr Brian Dow commented that when Chiron isolated their protein clone they used a radio immuno-assay (RIA) and reported on that in various papers in 1989, but it was never marketed.<sup>11</sup> Instead, the test was developed as the enzyme-linked immuno-assay (ELISA), which Ortho proceeded to market, as anticipated in the article.

**31.14** The *Blood Bank Week* article became a topic for discussion at the SNBTS Directors meeting on 14 June 1988. It was noted that Ortho Diagnostic Systems would soon market an ELISA test for NANB antibody. It was agreed that Professor John Cash would contact Ortho to enquire about the availability of the test in the UK.<sup>12</sup>

**31.15** Scientific details of the discovery were not released until April 1989 when two articles were published in the journal *Science*. The first article described the isolation by Chiron of a cloned protein derived from NANB Hepatitis.<sup>13</sup> The second, published in the same edition, gave details of the specific screening test developed to detect antibodies to the NANB Hepatitis virus that Chiron had discovered.<sup>14</sup> How that was achieved is described in Chapter 16; *Knowledge of Viral Hepatitis 3 – 1986 Onwards*, paragraphs 16.22–16.26. The Choo article in *Science* designated the hepatitis virus isolated by Chiron as ‘hepatitis C’ or ‘HCV’ and identified it as a major cause of both community-acquired and post-transfusion NANB Hepatitis, while recognising that other agents might be involved in transmitting NANB Hepatitis.<sup>15</sup>

### Professor Cash contacts Ortho

**31.16** On 5 July 1988, Professor Cash wrote to Dr Ginger Rosenberg of Chiron in the USA, asking for access, in due course, to some of their kits for SNBTS to evaluate.<sup>16</sup>

**31.17** On the same date, Professor Cash also wrote to Ortho in England seeking confirmation that Ortho would be marketing the recently announced Chiron kit. In addition, he asked when the kit would be marketed in the UK for full donation testing.<sup>17</sup>

<sup>15</sup> The need for a ‘type C’ hepatitis virus or viruses had been postulated by Feinstone and others in 1973: Chapter 14, *Knowledge of Viral Hepatitis 1*, paragraphs 14.64–14.68

<sup>16</sup> Letter [SNB.008.3584]

<sup>17</sup> Letter [SNB.008.3585]

**31.18** Mr Follett, of Ortho UK, replied to Professor Cash on 19 July:

Ortho ... do have an agreement with Chiron to develop and market the product but I do not know precisely when this product will be available. The best information I have been able to obtain is that the product may be available towards the end of 1989.<sup>18</sup>

**31.19** Mr Follett emphasised that there was a great deal of work to do regarding manufacturing and trials before the product would be available. There was a noticeable gap of time between the Ortho letter to Professor Cash of July 1988 and the suggested availability of the test in late 1989. While 12 months to develop an assay might appear to be quite a long time, Dr Dow commented in oral evidence that it probably takes longer nowadays to develop something into a useable assay that can be launched commercially.<sup>19</sup> In the event, Ortho had supplies of its first generation ELISA available for sale for 'in vitro diagnostic use' at the end of November 1989, as forecast.<sup>20</sup>

### **UK Health Departments<sup>21</sup> discussion of need for a new advisory group, July 1988**

**31.20** When Chiron made its announcement in May 1988, the United Kingdom Government did not have an advisory body competent to provide an assessment of the possible value of the American research, and in particular of the usefulness of the ELISA test in screening blood donors, as an aid to informing policy.

**31.21** Early in 1988 Dr Harold Gunson (Consultant Advisor to the Blood Transfusion Service in England and Wales)<sup>22</sup> had discussed with Dr Brian McClelland (SNBTS Regional Director, Edinburgh and SE Scotland Blood Transfusion Service) and Dr Hilary Pickles (DoH) the formation of a UK group to determine policy with respect to transfusion-transmitted diseases.<sup>23</sup> There appears to have been no progress with the proposal until July 1988.

**31.22** Coincidentally, and apparently separately from the above, on 14 July 1988 Dr E L Harris (Deputy Chief Medical Officer, England and Wales), sent a memorandum to various officials in the Health Departments, including Dr John Forrester (SHHD), proposing the creation of a group with a wide remit, an Advisory Committee on the Virological Safety of Blood (ACVSB).<sup>24</sup> It noted that concerns had been raised at a recent meeting of the Expert Advisory Group on Aids (EAGA) about the lack of advice available to ensure, generally, the virological safety of blood in the UK. Since viruses other than HIV1 and HIV2 were involved, EAGA was not felt to be an appropriate group for this. Having reviewed the existing advisory bodies, Dr Harris concluded that there was no suitable existing body and suggested a new advisory group. The new group would advise on tests for NANB Hepatitis, among other virus infections. To avoid both budgetary issues, and the need to refer the proposal to Ministers, the new group would be brought under the wing of

<sup>18</sup> Letter [SNB.008.3586] (*emphasis in original*)

<sup>19</sup> Day 67, page 93

<sup>20</sup> Letter from Ortho Diagnostics to Professor Cash dated 27 November 1989 [SNB.006.1560]

<sup>21</sup> The DHSS ceased to exist on 28 November 1988 in terms of the Transfer of Functions (Health and Social Security) Order 1988 when it was split into two. Health functions were taken over by the Department of Health (DoH) from that date. Since accurate designation is not relevant for the purposes of this chapter, the Department will be referred to as the DoH throughout.

<sup>22</sup> Dr Gunson's position was the nearest equivalent to Professor Cash's in Scotland and for convenience he is referred to as the National Director of the NBTS.

<sup>23</sup> Introductory comments in the Minutes of the First Meeting of the UK Advisory Committee on Transfusion Transmitted Diseases held on Friday 24 February 1989 [SNB.006.1975] stated that the meeting between Drs Gunson, McClelland and Pickles was 'about a year' before that first meeting of the ACTTD.

<sup>24</sup> Dr Harris' memo [SGH.003.1265]

an existing body, the Advisory Committee on the NBTS.<sup>25</sup> Dr Harris included suggestions for its terms of reference and membership. He did not consider that there was a need to consult Ministers on the proposal and hoped to be able to bring the group together 'shortly'.

**31.23** The EAGA's role had already become controversial. Dr McClelland observed in oral evidence that both he and Professor Cash had been members of the EAGA and made themselves 'unpopular' by exploring how other infection-related matters could be dealt with on a UK basis. This had not been acceptable to the Chairman of the group, as the EAGA's remit was intended to concentrate exclusively on AIDS.<sup>26</sup>

**31.24** Dr Harris's memorandum did not appear to be a reaction to Chiron's announcement. The note on NANB Hepatitis commented: 'no direct marker at present; dispute over indirect markers. No routine testing now'.<sup>27</sup> Around this time people involved in blood transfusion issues were anticipating developments in NANB Hepatitis research and Chiron's announcement was known in UK transfusion circles, but it was not referred to in Dr Harris' memorandum.

**31.25** In a letter dated 18 July 1988 to Dr Pickles, Dr Forrester (SHHD) welcomed the proposal to create the ACVSB.<sup>28</sup> He agreed with the proposal that Dr Robert (Bob) Perry (PFC) should be a member of the new committee and proposed Professor Stan Urbaniak (SNBTS, Aberdeen) as the member for the SNBTS. That proposal appears to have been made without reference to Professor Cash or the SNBTS. Dr Forrester was happy to act as an observer.

**31.26** Professor Cash also welcomed the creation of the proposed group, though it appears that he was not fully informed. In a letter dated 19 July 1988 to Dr Pickles he advised that he was pleased to learn (from Dr Pickles) that discussions were taking place which would hopefully lead to the establishment of a UK group which would concern itself with the long-term problems associated with the microbial screening of blood donations.<sup>29</sup> It appears, however, that he was unaware that Dr Forrester had already made a suggestion as to who would be a suitable member from the SNBTS. Professor Cash indicated in his letter that he would appreciate the opportunity, in due course, to provide an input into the membership of the new committee.

**31.27** The proposal for a new group under the aegis of the DoH did not resurface until October 1988, by which time the proposal had changed and the scope of the DoH proposals had become broader.

#### *Formation of two advisory groups: ACVSB and ACTTD*

**31.28** Mr Malcolm A Harris wrote to Mr Duncan Macniven (Assistant Secretary at SHHD) on 25 October 1988.<sup>30</sup> He attached a draft submission to Ministers on the setting up of the Advisory Committee on the Virological Safety of Blood (ACVSB).<sup>31</sup>

<sup>25</sup> Ibid [SGH.003.1265] at 1266

<sup>26</sup> Day 68, page 160

<sup>27</sup> Dr Harris' memo [SGH.003.1265] at 1266

<sup>28</sup> Letter [SGH.003.1264]

<sup>29</sup> Letter [SNB.006.1010]

<sup>30</sup> Letter [SGH.003.1257]

<sup>31</sup> Draft submission [SGH.003.1235]

**31.29** By way of background, the draft commented that concern over the safety of the blood supply had been heightened by greater public and clinical awareness of the potential for viral contamination and new developments in product liability legislation. The need for a new advisory body was set out:

Decisions on testing for particular viruses involve a range of disciplines. Clinical and scientific expertise must be balanced by expertise representing the practicality and cost/benefit of testing. Neither the CSM the CBLA nor the BTS have the remit or expertise to take this broader approach. Their conflicting interests are ultimately in no-one's best interest.

The new advisory group will embrace the expertise of all interested groups ....

There is no suitable existing body. All of the UK must be covered.<sup>32</sup>

**31.30** The terms of reference proposed were:

To advise the Health Departments of the UK on measures to ensure the virological safety of blood, whilst maintaining adequate supplies of appropriate quality for both immediate use and for plasma processing.<sup>33</sup>

**31.31** Mr Harris asked for confirmation that the SHHD was content with the proposals and in particular that:

- (i) the committee would operate on a UK basis;
- (ii) the committee would report to the CMOs of all four health departments;
- (iii) the terms of reference were acceptable;
- (iv) the membership and observers arrangements were acceptable.<sup>34</sup>

**31.32** Mr Macniven replied by letter dated 11 November 1988 and confirmed his agreement with the proposals.<sup>35</sup> He was content that the committee should operate on a UK basis and report to the Chief Medical Officers (CMOs) of all four health departments. The terms of reference were acceptable, as was its proposed membership. The proposed Scottish members remained Dr Perry and Professor (then Dr) Urbaniak. It is not known how Mr Macniven reached his views.

**31.33** In the meantime, concern had been growing in the Blood Transfusion Services over the lack of progress in making provision for uniform advice on microbiological testing, as the EAGA had 'withdrawn from the field'.<sup>36</sup> The issue arose at a meeting of the Directors of the SNBTS on 13 December 1988, primarily in the context of AIDS. Dr Gunson and Dr William (Bill) Wagstaff of the English NBTS were in attendance, as was Professor Cash. The minutes of the meeting noted that the DoH had indicated some nine months previously that it would take the initiative, but that this had not happened 'and meanwhile certain problems needed to be addressed'.<sup>37</sup> Mr Robert (Rab) Panton (SHHD) reported that his medical colleagues would welcome the formation of a professional group. After discussion, it was agreed that the UK Blood Transfusion Services should establish a group to advise

<sup>36</sup> Minutes of a Directors' Meeting Held in the HQ Unit on 13 December 1988 [SNB.002.7350] at 7351

<sup>37</sup> Ibid [SNB.002.7350] at 7351

the Departments of Health on policy. Professor Cash and Dr Gunson, together with the SHHD, would put pressure on the Department of Health to bring that about.

**31.34** In relation to the introduction of surrogate donation testing for NANB Hepatitis (a topic discussed more fully in Chapter 27 of this Report), the meeting agreed that the task would be dealt with by the proposed group: Scottish Directors would not commence surrogate testing until the DoH and the SHHD supported and funded it. Discussion of Chiron's test was not noted in the minutes of the meeting.<sup>38</sup>

**31.35** The decisions at the meeting of SNBTS Directors on 13 December 1988 had immediate impact. On 9 January 1989 Dr McIntyre wrote to Dr Pickles. He sent her an extract from the meeting, pointing out that Dr Gunson and Dr Wagstaff had been present. He expressed his concern that if the Health Departments did not establish an advisory committee, the Transfusion Services would do so. He wrote:

This method of approaching the problem we consider to be unsatisfactory and we suspect that the decisions reached might be influenced to a considerable extent by the views of the Transfusion Directors. As this is a matter which has policy implications and will be of considerable interest to Ministers we feel that this Advisory Committee should be set up jointly by the Departments.<sup>39</sup>

**31.36** Dr McIntyre went on to observe that in Scotland there was 'considerable pressure' from the SNBTS to fund the introduction of additional virological testing, but the SHHD was of the opinion it should be tackled on a UK-wide basis. He asked for reassurance that the Department of Health would take steps in this matter, as the SHHD 'would not like to be forced into a course of action which might have repercussions for the UK as a whole'.

**31.37** The issue of the formation of the ACVSB was followed up by a letter dated 13 January 1989 from the Parliamentary Under-Secretary of State for Health, Roger Freeman, to the then Parliamentary Under-Secretary of State at the Scottish Office, Michael Forsyth, asking for Mr Forsyth's agreement to the proposal.<sup>40</sup> Mr Freeman commented that it seemed timely for the Blood Transfusion Services and all other interested parties to 'act in unison on this important matter'. Mr George Tucker (Assistant Secretary, SHHD and Mr Macniven's successor) told the Inquiry in oral evidence that it was common for government officials to consult initially on a proposal or plan, before the Ministers would correspond directly and notify their agreement.<sup>41</sup>

**31.38** On 6 February 1989 Mr Macniven sent a memorandum to Mr Forsyth's Private Secretary to recommend that the Minister should agree to Mr Freeman's proposals.<sup>42</sup>

**31.39** Mr Forsyth wrote to Mr Freeman on 8 February to confirm his agreement.<sup>43</sup> The Scottish members of the committee remained Professor Urbaniak and Dr Perry at this stage.

**31.40** The UK Health Ministers' decision to set up the ACVSB, originally proposed the year before, was intimated in a letter of 8 March 1989 sent out by Dr Harris.<sup>44</sup> Ministers believed

it was 'of the utmost importance that the UK Blood Transfusion Services act in unison on this subject, and with the benefit of the best advice available'. Government policy aimed at securing common action throughout the Health Departments was established at this time.

### **The initial meetings of the two groups**

**31.41** The decision at the meeting of the SNBTS Directors on 13 December 1988 to form a UK blood transfusion services group on microbiological testing was implemented very efficiently. The resulting group, the Advisory Committee on Transfusion Transmitted Diseases (ACTTD), held its first meeting on 24 February 1989.<sup>45</sup> This was about six weeks before the group established by the Departments of Health, the ACVSB, first met. Dr Gunson, in his introduction to the initial meeting of the ACTTD, was able to report that the DoH was in the process of forming another group with a brief that would be much wider than simply blood transfusion medicine. It appears to have been understood at that stage that the remit of the ACVSB would be very broad, and that the ACTTD's remit would be narrower, concentrating on transfusion-transmitted diseases.

**31.42** The ACTTD had three members from Scotland: Professor Cash, Dr Ruthven Mitchell and Dr Eddie Follett, (Hepatitis Reference Laboratory, Ruchill Hospital, Glasgow) along with four English members.<sup>46</sup> Dr McClelland thought members would have been invited by Dr Gunson.<sup>47</sup> He added that a working group like this tended to consider where they could find the best input, rather than looking at it on a political or geographical basis.

**31.43** Dr Mitchell commented in his statement that membership of the ACTTD was nominated by peer opinion and based on 'individual interest, knowledge and ability'.<sup>48</sup> He was to be a member of both the ACTTD and the ACVSB, and assumed this was because he represented the largest transfusion centre in Scotland. Professor Cash confirmed in his statement he had nominated Dr Mitchell for membership of the ACTTD as he had led the SNBTS team responsible for testing kit evaluations and could be a valuable link between the ACVSB and the ACTTD.<sup>49</sup>

**31.44** The terms of reference adopted by the ACTTD at its first meeting were:

1. To consider the epidemiological, clinical and laboratory aspects of diseases which may be transmitted by the transfusion of blood and blood products.
2. To determine the appropriate policy which should be implemented by the UK Blood Transfusion Services for the control of transfusion-transmitted diseases.
3. To advise the Departments of Health accordingly.<sup>50</sup>

**31.45** Dr Gunson's introduction to the first meeting of the ACTTD on 24 February 1989<sup>51</sup> recognised that the ACTTD and the ACVSB had different roles.

<sup>50</sup> Draft Terms of Reference [SNB.006.1923]

<sup>51</sup> Minutes [SNB.006.1975]

**31.46** Dr Gunson told the meeting that Ortho had approached him with respect to conducting trials of the Chiron test in the UK. He undertook to report to the committee when further details became available.<sup>52</sup>

**31.47** The ACVSB held its first meeting on 4 April 1989<sup>53</sup> when the committee adopted the terms of reference outlined in Mr Harris' submission to Ministers quoted above. They added a qualification, however:

Note remit is UK-wide. Our concern is matters of major policy, not the detailed implementation of policy. The intention is that any proposed changes in requirements or practices of one of the major groups (transfusion service, fractionators, regulators) that has major implications for the others are brought to this group first for discussion.<sup>54</sup>

**31.48** Terms of reference of related groups were noted as follows:

- the UK Advisory Committee on Transfusion Transmitted Diseases (ACTTD) would be considering many of the same issues as the ACVSB, but only from a transfusion viewpoint;
- a BTS/National Institute for Biological Standards and Control (NIBSC) group formed between the NBTS/SNBTS and the NIBSC to formulate scientific guidelines for the standardisation and safety of blood and blood products; and
- the Advisory Group on Hepatitis, which provided 'medical advice to the Chief Medical Officers of the Health Departments on all aspects of communicable hepatitis' and had the appropriate technical expertise for detailed consideration of the technical aspects of screening donors and plasma for various forms of hepatitis, leaving the ACVSB to consider the wider policy issues.<sup>55</sup>

**31.49** The ACVSB was chaired by Dr Harris. The initial members comprised Dr Gunson (NBTS), Dr Lane (BPL), Dr Minor (NIBSC), Dr Mortimer (PHLS), Dr Summerfield (Middlesbrough Haemophilia Centre), Dr Tuddenham (MRC) and Professor Zuckerman (Professor of Medical Microbiology). As regards the two members from Scotland, by the first meeting, on 4 April 1989, Professor Urbaniak had been replaced by Dr Mitchell, although Dr Mitchell did not in fact attend the first meeting.<sup>56</sup> Dr Perry remained a member of the ACVSB from its inception.<sup>57</sup> There was to be one Scottish observer from the Scottish Home and Health Department and Dr Archie McIntyre took on that role.<sup>58</sup> One important consequence of the selection of Scottish members was that Professor Cash was not involved in the work of the ACVSB while Dr Gunson, his equivalent in the NBTS, was involved. Dr Perry was a member as a fractionator and not because he had expertise in the microbiological safety of blood.<sup>59</sup> Members were chosen in an individual capacity, and not as representatives of their parent organisations.<sup>60</sup> The omission of Professor Cash was to have consequences.

<sup>58</sup> Ibid, page 14

<sup>59</sup> Ibid, page 7

<sup>60</sup> Ibid, page 18

**31.50** Over the period to mid-1991 which was of particular importance in the context of this chapter there were a few changes in membership of the ACVSB. Dr Jeremy Metters replaced Dr Harris as DCMO and as chairman of the committee by 3 July 1989. Professor Tedder, Middlesex Hospital, joined and attended the second meeting of the committee on 22 May 1989. Dr Tuddenham resigned before the ninth meeting on 25 February 1990 and was replaced by Dr Wensley. Dr Summerfield did not attend regularly. But otherwise the membership of the ACVSB was stable and meetings were well attended.

**31.51** At the beginning of the meeting on 4 April 1989, Dr Harris made a comment that was to have important consequences for relationships between the ACVSB and the transfusion services and, in particular, the ACTTD:

He reminded members that their advice on the subjects under discussion could be publicly sensitive and should not be discussed outside the Committee, unless specifically indicated.<sup>61</sup>

**31.52** The minutes recorded that it was the intention that the next meeting of the committee should concentrate on viral hepatitis.<sup>62</sup>

**31.53** The second meeting of the ACTTD took place on 19 May 1989.<sup>63</sup> From reviewing the minutes, it appears that comparatively little time was spent discussing developments in Hepatitis C screening. Dr John Barbara (NBTS, Edgware, North London) reported that ordinary donor samples saved and stored from the tri-centre trial of ALT testing (discussed in Chapter 27, *Surrogate Testing of Donated Blood for non-A, non-B Hepatitis*, paragraphs 27.245–27.246) were being tested with the trial Ortho anti-HCV assay at a rate of 400 per day, before proceeding with selected groups. The test was running consistently with the manufacturer's expectations. Under the heading in the minutes 'Anti-HCV testing of donations from Scotland' it was noted:

Professor Cash reported that the SNBTS would be interested in taking part in evaluative trials of the Ortho Pharmaceutical Company's Chiron test and said he would be grateful if Dr Gunson would contact him about this matter. In particular the West of Scotland centre has a bank of frozen donor samples already tested for ALT, from which further samples are available of i.v. IgG known to have produced raised ALT levels in recipients.<sup>64</sup>

**31.54** Dr Dow commented in oral evidence that Professor Cash, as National Medical Director, was keen to ensure that the SNBTS remained at the forefront of test developments.<sup>65</sup>

**31.55** The second meeting of the ACVSB on 22 May 1989 tackled the topic of hepatitis.<sup>66</sup> Members advised that although colleagues in the US considered only one virus caused NANB, there may be two or more. The Chiron test was estimated to pick up only approximately 50% of cases and there was a need for caution. There had been enormous progress and once the sequence was published it would be possible to test without recourse to Chiron. In oral evidence, Dr Perry said that he was unclear what that meant other than that the release of data could pave the way for other manufacturers to come

<sup>65</sup> Day 67, page 103

<sup>66</sup> Meeting [SNB.001.9416]

up with tests.<sup>67</sup> This appears to be a plausible explanation. Dr Perry could not recall any sense in which the ACVSB was waiting for a British developed test to become available, and using that rather than relying on one that originated in the USA.<sup>68</sup> However, the minute remains somewhat obscure.

**31.56** The minutes noted that the DoH would keep the issue of testing under review. The use of Chiron or surrogate testing would be influenced by Chiron data once released; the Medical Research Council (MRC) might be asked to consider the data. The minute notes that members regarded the matter as a 'priority'.<sup>69</sup>

**31.57** The ACVSB met for the third time on 3 July 1989. Dr Metters was now its Chairman. The meeting considered the topic of non-A, non-B Hepatitis.<sup>70</sup> Dr Philip Mortimer had attended a recent conference, and come away with the view that 'there was a persuasive case that the Chiron test results were reliable'. As a result the Chairman asked for all available data on NANB Hepatitis to be compiled and given to the committee for consideration at the next meeting.<sup>71</sup>

**31.58** In his evidence Dr Perry agreed that the impression created by the reported discussion was that there was no detectable sense of urgency in the ACVSB to introduce testing at this time, stating that:

[T]here was a greater emphasis on understanding the science than there was in saying, "We must introduce a test as soon as possible" .... There was certainly no discussion ... of a putative date at which the test could or should be introduced.<sup>72</sup>

**31.59** Dr Perry went on:

My general sense of the meeting was that there were some exciting international developments in relation to a specific HCV test but that it was far from clear when or if a test suitable for routine use (including confirmation) would emerge.<sup>73</sup>

**31.60** So far as the committee was concerned, all options were to be kept open. At this stage, that was understandable. Apprehension that the Chiron test would identify 50% of cases of virus infection in donations left 50% of cases unidentified. Depending on the outcome of early studies of the evaluation of the Ortho test in use in the UK population, ALT and anti-HBc were the only tests currently available that might provide surrogate screening in the UK donor population for agents other than HCV.

**31.61** In his statement Dr Perry responded to a question whether it was a correct impression to derive from correspondence around this time that the principle of introducing a further test designed to reduce the incidence of post-transfusion hepatitis had not yet been determined. He replied:

I believe this impression is correct. It was certainly periodically emphasised by Dr Metters at ACVSB meetings that the primary purpose of the committee was

<sup>72</sup> Day 68, page 35

<sup>73</sup> Dr Perry's Statement [PEN.017.2108] at 2111

to establish the policy and principle for introduction of new screening tests. At this time such a policy had neither been stated or agreed – notwithstanding the fact that many believed it to be only a matter of time.<sup>74</sup>

**31.62** Dr Perry added in oral testimony that he would not have considered himself, in summer 1989, to be someone who thought it was only a matter of time before testing for Hepatitis C was introduced, although he came to that view fairly soon afterwards.<sup>75</sup>

**31.63** When asked about Dr McIntyre's view, stated in a letter to Professor Cash on 2 August 1989,<sup>76</sup> that testing would be introduced simultaneously throughout the UK, Dr Perry thought it was the 'accepted view of the committee, that this would be a UK decision and implemented in a co-ordinated manner across the UK'.<sup>77</sup>

**31.64** Dr Perry had no knowledge of the formal position in Scotland on the procedure for translating a 'UK decision' into local application. He added in his statement: '[R]ather it was understood that a decision by DOH (and presumably English Ministers) would be replicated in Scotland'.<sup>78</sup>

### Events in summer 1989

**31.65** In the meantime, as the summer of 1989 progressed, several interrelated issues emerged, including collaboration between the NBTS and SNBTS at a practical level in relation to evaluation of Ortho's kit and the introduction of screening; Ortho's marketing strategies; and expectations of the role of government in the introduction of screening.

**31.66** In June 1989 Professor Cash had arranged with Ortho to obtain kits for research evaluation. A preliminary report on the project, by Dr Dow, Mr A Barr and Dr Mitchell, was prepared in October 1989 and is referred to below. SNBTS had a clear and obvious interest in developing an understanding of the new test as soon as possible given the central importance of eliminating or reducing the transmission of infection by transfusion. However, Professor Cash offered a more particular explanation.

**31.67** Professor Cash commented in oral evidence that the SHHD, through Dr McIntyre, had previously 'banned' Dr Mitchell's team from involvement in the testing of HIV kits as it was to be done 'centrally'.<sup>79</sup> With the HCV test kits, the SNBTS was determined to have some control and to do their own test of the earliest kit they could obtain. He feared that the SHHD would defer to the DoH in London, as they had done with HIV testing.<sup>80</sup> The SNBTS concern, according to Professor Cash, was the effect it would have on donor perception of the screening if there was controversy over its accuracy, especially; in the initial stages a confirmatory test was unlikely to be available.<sup>81</sup>

**31.68** Professor Cash was keen that the SNBTS should generate their own independent data as quickly as possible, that could be used as a 'lever' for influencing central action later on.<sup>82</sup> This 'lever' was a way to get Dr Mitchell and his team involved in UK-wide

<sup>77</sup> Day 68, page 36

<sup>78</sup> Dr Perry's Statement [PEN.017.2108] at 2113

<sup>79</sup> There is a detailed description of the steps taken by SNBTS to evaluate HIV screening kits to be found in paragraphs 30.71–30.87 of Chapter 30, *Screening of Donated Blood for HIV*. The issue over testing using live HIV became complex.

<sup>80</sup> Professor Cash's Statement [PEN.017.2094] at 2096; Day 72, page 115

<sup>81</sup> Day 72, pages 114–115

<sup>82</sup> Professor Cash's Statement [PEN.017.2094] at 2096

testing that he envisaged would be run by the DoH.<sup>83</sup> He wanted to ensure that Scotland had 'a place in the team, the UK team', that was involved in evaluation of test kits.<sup>84</sup> He told the Inquiry in his statement that the SNBTS thought that engagement with Ortho might expedite outcomes from their confirmatory testing developments.<sup>85</sup>

**31.69** Evaluation of the Ortho kits proceeded, and information was exchanged between the NBTS and the SNBTS. Dr Gunson wrote to Professor Cash on 26 July 1989 to express his pleasure that the SNBTS was to test 5000 samples with the Ortho kit.<sup>86</sup> Dr Barbara (Edgware, North London) had almost completed testing 9000 samples and the results would be sent to Professor Cash when available. The methodology adopted was explained by Dr Dow. A positive result on a first test was followed by repetition of the test, twice if the second test was negative. A sample which was positive on both the initial and one other of the two subsequent tests was classified as a 'repeat reactive'.<sup>87</sup> A sample that was reactive with the first test, but negative with the two subsequent tests would be classified as an 'initial reactive'.<sup>88</sup>

**31.70** Dr Gunson went on to emphasise the importance of close collaboration between the SNBTS and the NBTS. He concluded by saying:

My view is that we should not move until we know what our European colleagues are doing. For the U.K. it is important that the SNBTS and the NBTS act in close collaboration since I can foresee difficulties if one of us introduced the test unilaterally.<sup>89</sup>

**31.71** In his reply of 28 July 1989 Professor Cash confirmed that close collaboration seemed certain, since the SNBTS would not move unilaterally unless instructed to do so by the SHHD.<sup>90</sup> He commented that he had indicated to Ortho that the SNBTS would not be able to discuss contracts for supply of the test kits unless instructed to do so by the SHHD. Professor Cash agreed in oral testimony that he and Dr Gunson were planning to work together on the introduction of screening and that he was happy with that as the best course of action.<sup>91</sup> Ultimately, a common start date was agreed and implemented. However, there was not a uniform pattern of concerted action between the NBTS and the SNBTS in arriving at that outcome.

**31.72** Professor Cash also wrote to Dr McIntyre on 28 July 1989 to confirm the terms of a recent telephone conversation.<sup>92</sup> Dr McIntyre had indicated that the decision to commence routine donation testing, using the Ortho test, would be made by the SHHD and it would not be appropriate for senior SNBTS managers to liaise directly with Ortho. Professor Cash told the Inquiry in his statement that the letter was drafted primarily to confirm and put on record important conversations he had had with Dr McIntyre, and to ensure the SNBTS directors were fully briefed on SHHD policy.<sup>93</sup>

<sup>93</sup> Professor Cash's Statement [PEN.017.2094] at 2097

**31.73** Dr McIntyre replied in a letter dated 2 August 1989. The terms and the tone of the letter are instructive:

As you are aware there is a UK Advisory Committee on the Virological Safety of Blood which is meeting regularly and considering the sensitivity and specificity of the tests available for a variety of infective agents including [the Chiron test and others]. If it is considered desirable to introduce a further routine screening test for blood donors I understand that this will be done simultaneously throughout the UK – as was done in the case of the current HIV test.

I am sending a copy of this letter to Dr Jeremy Metters, Deputy Chief Medical officer at the Department of Health and to administrative colleagues here in SHHD.<sup>94</sup>

**31.74** Dr McIntyre was a regular SHHD observer at ACVSB meetings, and Dr Perry thought he would have been aware of the DoH view that any new test would be introduced simultaneously throughout the UK.<sup>95</sup>

**31.75** Professor Cash wrote to the SNBTS directors on 3 August 1989.<sup>96</sup> In his letter he advised that he believed that it was only a matter of time before screening using the Chiron test was introduced and that while he did not know when screening would commence he thought the start date would be some time after April 1990. That was much earlier than screening in fact began. Professor Cash remarked in his Inquiry statement that at the date of his letter he thought the assessment of the Ortho kit would reveal a kit with acceptable specificity and sensitivity so that screening could commence.<sup>97</sup> Professor Cash's comment in his letter of 3 August that '[t]he decision to commence testing will be a UK one and will be made by the UK Departments of Health', was tempered by adding that '[t]he start date ... will, as with HIV-1, also be a matter for central government decision, with, of course, appropriate consultation with the UK BTS directors'.<sup>98</sup> He concluded his letter by stating that he had 'started a battle' with Ortho on the need for confirmation testing, which he intended taking as high as he could in the Departments of Health.

**31.76** Dr Mitchell's view at the time appears to have been that sensitivity and specificity of the test remained a problem that required improvement to the test to avoid the problems of false positive and negative results.<sup>99</sup>

**31.77** Dr Gunson wrote to his NBTS transfusion directors on 18 August 1989 and copied the letter to Professor Cash.<sup>100</sup> He emphasised the need to act in a coordinated fashion, both nationally and with Scotland, with regard to the introduction of routine screening. According to Mr McIntosh in oral evidence, the regional transfusion centres in England and Wales did not report to Dr Gunson; rather, they reported to their local health authorities. In his view, Dr Gunson and his central blood authority team did not have executive authority.<sup>101</sup>

<sup>100</sup> Letter [SNB.006.1426]

<sup>101</sup> Day 70, page 83

**31.78** Mr Tucker was an Assistant Secretary in SHHD whose role was to ‘quality control check briefings and to channel advice to Ministers’.<sup>102</sup> He sent a memorandum to Mr Forsyth on 23 August 1989 regarding an article on testing for Hepatitis C which appeared in *The Guardian* on the same day.<sup>103</sup> Mr Tucker’s memo confirmed that the introduction of HCV screening of blood donors was a UK issue and that the DoH would take the lead, but that SHHD and SNBTS would be represented in meetings and the appropriate Minister would be consulted before any decision was taken.

**31.79** By this time there was growing concern within SNBTS that their Directors did not have sufficient information about the work of the ACVSB. The issue of the reporting of events at the ACVSB was discussed at the SNBTS Directors’ meeting on 29 September 1989.<sup>104</sup> By then, it was reported on behalf of Mr Panton that there had been progress. It would be in order for Dr Perry and Dr Mitchell, as members of the ACVSB, to report the Committee’s discussions and recommendations to the other SNBTS Directors. Miss Corrie, the minute taker, was to seek written confirmation of this from Mr Panton, and to ask if the Directors could have copies of the ACVSB minutes.

**31.80** At the SNBTS Directors meeting of 13 February 1990 it was noted that ‘it would be in order for Dr Perry and Dr Mitchell to report the discussions and findings of the Committee to fellow Directors, but ... the minutes could not be copied to them’.<sup>105</sup> The minutes could, however, be passed around and discussed at the Directors’ meetings informally. The same position was said to apply in the NBTS. Thus the provision for relaxation of confidentiality noted by Dr Harris at the first meeting of the ACVSB was given practical effect.

### Medical literature on testing in summer 1989

**31.81** Before returning to events in the UK, it is appropriate to note what was happening in the wider scientific community, as a great deal of research was being published at the time. As noted above,<sup>106</sup> *Science* published an article by Kuo and others on 21 April 1989 giving scientific information on the Chiron discovery and the research behind it.<sup>107</sup> A radio-immuno assay was used in the research phase leading to the announcement of the discovery. A radio-immuno assay utilises radioactive material and the research team was encouraged, according to Dr Dow, to discontinue use of that technology, and to develop an ELISA rather than expose workers in general laboratories to radioactivity. The researchers had also moved on from the initial clone and had found a slightly longer strip of the NANB Hepatitis virus genome.<sup>108</sup> The ELISA assay performed well using ‘well pedigreed’ NANB Hepatitis samples,<sup>109</sup> showing high levels of reaction in those samples when compared with reactions to alcoholic and other forms of non-viral hepatitis. The ELISA tested for C100 antibodies, a late-appearing antibody in terms of the period lapsed since infection. Researchers noted later that antibodies in drug addicts in the acute early stage of NANB Hepatitis were not detected by this test. The second generation tests developed later were able to detect earlier appearing antibodies, thus shrinking the ‘window period’ of infectivity.<sup>110</sup>

<sup>102</sup> Statement [PEN.017.2060] at 2061

<sup>108</sup> Day 67, pages 96–98

<sup>109</sup> ‘Well pedigreed’ samples were those from subjects, animal and human, who, clinically, were known to be suffering from NANB Hepatitis

<sup>110</sup> Day 67, pages 98-99

**31.82** With regard to the *Science* article, Dr McClelland commented in oral evidence that it would have been difficult to be confident about any estimate of the sensitivity of the assay when it was completely new. There was no reliable, independently certified set of known positives to use as controls. Furthermore, any new technique used by the research laboratory that developed it would work better than in the field: the research scientists would know its 'little ins and outs' and 'technical foibles'. They would almost always produce better results in the early days than would be produced by people from other laboratories.<sup>111</sup>

**31.83** *The Lancet* of 5 August 1989 contained an editorial concerning the Ortho test entitled 'Will the real hepatitis C stand up?'.<sup>112</sup> The editorial concluded: 'It would be logical to confer the title of hepatitis C on the newcomer'.<sup>113</sup> The issue also included a series of results of the new test system from Spain and Holland and two from Germany.<sup>114</sup>

**31.84** The editorial noted:

In general, the results support the sensitivity and specificity of the test system, and underline both the urgency of making the test system available for blood donor screening, and the importance of despositing [*sic*] the sequence of the viral genome in the GenBank database where it would be available to the wider scientific community.<sup>115</sup>

**31.85** The research reported from Spain was focused on prevalence in patients at high risk of infection.<sup>116</sup> Dr Dow was referred to Table I in the paper and was impressed with the figures for positive tests, as the percentage figures were as high as he would expect from high-risk groups.<sup>117</sup> The test at this stage appeared to have good sensitivity in high-risk groups where the virus would be expected.<sup>118</sup> The figure of 64% for positive reactions in a group of people with haemophilia was very close to the finding of anti-HCV positivity in patients with haemophilia in the (subsequent) Scottish paper.<sup>119</sup>

**31.86** The authors stated that:

Our results show that HCV accounts for most cases of post-transfusion hepatitis in Spain. Although seroconversion may occur during the acute phase of the infection (in about a third of cases), in more than half of our patients, anti-HCV antibodies were first detected 4-6 months after transfusion, and in some the antibody response was considerably later.<sup>120</sup>

<sup>111</sup> Day 69, pages 7–9

<sup>112</sup> 'Will the Real Hepatitis C Stand Up?', *The Lancet*, 5 August 1989 [LIT.001.3848]

<sup>113</sup> By the time of a subsequent editorial in *The Lancet* on 16 June 1990, 'Hepatitis C virus upstanding' [LIT.001.3879] it was stated that 'Hepatitis C virus is believed to be the main blood borne [NANB] hepatitis virus'

Day 67, page 123

<sup>114</sup> 'Will the Real Hepatitis C Stand Up?', *The Lancet*, 5 August 1989 [LIT.001.3848] at 3849

<sup>115</sup> Esteban et al, 'Hepatitis C virus antibodies among risk groups in Spain', *The Lancet*, 5 August 1989 [LIT.001.3834]. The 'risk groups' were noted as being: patients with post-transfusion NANBH, patients with chronic hepatitis, haemophiliacs, intravenous drug users, haemodialysis patients, homosexual men and female contacts of drug users.

Day 67, page 127

<sup>116</sup> See the high rates of positive results in those with post-transfusion NANBH, those with chronic NANBH and intravenous drug abusers shown in table 1 [LIT.001.3834] at 3835.

<sup>117</sup> Day 67, page 128; SNBTS Evaluation of the Ortho HCV antibody ELISA test system, Dr B Dow et al, October 1989 [SNB.006.1596]

<sup>118</sup> Esteban et al, 'Hepatitis C virus antibodies among risk groups in Spain', *The Lancet*, 5 August 1989 [LIT.001.3834] at 3836

**31.87** According to Dr Dow, the authors referred here to a time delay following infection and before the RIA would pick up the HCV antibodies.<sup>121</sup> The authors themselves commented: 'This delayed response could explain why anti-HCV was not detected in all our post-transfusion cases'.<sup>122</sup>

**31.88** The Dutch study in *The Lancet*<sup>123</sup> was a prospective study of patients undergoing heart surgery. Post Transfusion-NANB Hepatitis (PT-NANB Hepatitis) developed in nine patients, and four of those seroconverted. The authors commented:

We have shown that in a Dutch blood donor population the new anti-HCV RIA developed by Chiron specifically identifies blood products associated with NANB hepatitis in patients who have received transfusions .... Sensitivity of the assay for detecting probable NANB infected blood products was 67% in our study population.<sup>124</sup>

**31.89** The patients studied were in a group of people assumed to have a low incidence of HCV. The number of cases of PT-NANB Hepatitis was small. The authors concluded:

Despite its limited sensitivity, the high specificity of this first generation anti-HCV assay should permit greatly improved donor screening procedures for the prevention of PTH-NANB.<sup>125</sup>

**31.90** The German research published in the same issue of *The Lancet*<sup>126</sup> related to a study of donors at four German blood banks using the Ortho ELISA. By categorising donors in different ways the researchers found that samples from certain groups were repeatedly reactive. They observed, however, that in the absence of a confirmatory test, the true frequency of HCV infection in their population remained to be determined. A note of caution was sounded regarding confirmatory testing:

The use of the same recombinant antigen material – ie, that constituting the solid material in the EIA – for a confirmatory test (eg, immunoblot) would not be satisfactory scientifically.<sup>127</sup>

**31.91** The same edition of *The Lancet* contained a second letter from researchers in Germany.<sup>128</sup> This study looked at patients rather than donors, using the Ortho ELISA tests. Researchers looked at patients with acute and chronic NANB Hepatitis and at high-risk patients – haemophilia patients, patients on haemodialysis and drug addicts. They reported:

Seroconversion seems to occur late after onset of disease since acute post-transfusion NANBH patients have a lower prevalence of anti-HCV than chronic cases, and seroconversion occurred at 3-4 months post exposure in 3 patients with haemophilia. The low prevalence of anti-HCV in haemodialysis patients in our study may reflect a selected population.<sup>129</sup>

<sup>129</sup> Ibid at [LIT.001.3856] at 3857

**31.92** On 26 August 1989 *The Lancet* published a letter written by Drs Contreras and Barbara from the North London BTC on the subject of 'Screening for hepatitis C antibody'.<sup>130</sup> The authors agreed that the Chiron/Ortho ELISA for anti-HCV was specific for the major agent causing post-transfusion NANB Hepatitis and was superior to all previous attempts at a test for the NANB virus. However, they struck a note of caution with regard to the screening of donors for anti-HCV:

As in any other assay, the predictive value of a positive result hinges on the prevalence of the marker in a given population. While the test scores well in panels of well-characterised NANB hepatitis sera and in samples from patients with a diagnosis of NANB hepatitis, we do not know the predictive value of the test in low prevalence populations, such as UK blood donors.<sup>131</sup>

**31.93** The authors went on to emphasise the importance of a confirmatory test to eliminate uncertain results, before realistic policies for generalised screening of blood donations could be implemented.

**31.94** In addition, the 26 August 1989 edition of *The Lancet* contained a letter by Professor Cash and Drs McClelland, Urbaniak, Brookes and Follett on the subject of screening for Hepatitis C.<sup>132</sup> They also emphasised the importance of a confirmatory test. Without such a reliable test there would be serious problems for blood transfusion services, which would probably be required to absorb the majority of counselling of sensitive donors. A repeatedly reactive ELISA test was 'suggestive but not definitive' evidence of the presence of HCV antibody. A confirmatory test which used the same antigen as the ELISA test was described as 'scientifically less than satisfactory' but 'better than nothing'. The authors urged Ortho to make available reagents and/or tests that would ensure that an assay system that was fundamentally different from the marketed ELISA test could be used for confirmatory testing.

### Supplementary and confirmatory tests

**31.95** As was implicit in the letter by Professor Cash and others, a 'confirmatory' test was ideally a test that was fundamentally different from the ELISA currently on the market, that would affirm the initial screening test, or not, and provide a reliable basis for diagnosis and counselling. Dr Dow commented that, in general terms, a confirmatory test would be better than a supplementary test.<sup>133</sup> Dr McClelland observed in oral testimony that the terms were very difficult to define because 'there are numerous definitions invented by various people'.<sup>134</sup> In his view, a confirmatory test should assist in deciding if a positive screening test result is a real or a false positive result. The type of test used for confirmation did not matter provided it could determine if an earlier test was truly positive. A 'supplementary' test, that simply repeated the initial screening test, was much less useful.<sup>135</sup>

**31.96** Professor Leikola observed in oral testimony:

[T]hat a true confirmatory test should be based on the principle that it is different from the original antibody/antigen reaction, in order to show from

<sup>130</sup> Contreras and Barbara, 'Screening for hepatitis C virus antibody', *The Lancet*, 26 August 1989: 505 [LIT.001.3858]. This referred to the NBTS assessment exercise discussed later: paragraphs 31.118–31.121

<sup>131</sup> Ibid [LIT.001.3858]

<sup>132</sup> Cash et al, 'Screening for hepatitis C virus antibody', *The Lancet*, 26 August 1989; 505 [LIT.001.3858]

<sup>133</sup> Day 67, page 140

<sup>134</sup> Day 69, page 24

<sup>135</sup> Ibid, page 25

another point of view that it really is a true reaction between the virus and the antibody.<sup>136</sup>

**31.97** The difficulty in the early days of anti-HCV testing was that there was only one antigen because only a small section of the virus had been isolated. As a result only one antibody was identified by the screening test, whether on initial or repeat testing. The recombinant immunoblot assay (RIBA) that Ortho developed later as a confirmatory test targeted the same antigen. For a test to be truly confirmatory it would be required to detect an antibody to some *other* part of the virus, or the virus itself. Because the RIBA looked for the *same* protein, it could only have been a 'supplementary' test and not 'confirmatory' of the initial screen result. By way of contrast, in later developments virus laboratories would test for the virus itself using a Polymerase Chain Reaction (PCR) test which was truly confirmatory because it is based on a different principle from the initial screening tests.<sup>137</sup>

### The position in Finland in 1989–90

**31.98** Professor Juhani Leikola assisted the Inquiry as expert witness and spoke to events in Finland, which provide a useful comparison to events in Scotland and in the UK as a whole. His general evidence had a basis in the work of the Finnish Red Cross. There were structural differences between the blood transfusion services in Finland and in the UK which have to be taken into account, but these do not invalidate the comparison. Finland is a small country, where the prevalence of NANB Hepatitis was very low, at less than one per cent. By the end of 1989, it was known to the UK Blood Transfusion Services, including the SNBTS Directors, that the Finnish Red Cross had arranged with Chiron to test samples at the same time as evaluation was proceeding in the United Kingdom.<sup>138</sup>

**31.99** Professor Leikola was approached by Ortho in the spring of 1989 and asked to arrange a study of their new test kit, together with researchers from Sweden and Denmark.<sup>139</sup> There was considerable contact between these countries in the blood transfusion field, although the organisation of their individual transfusion systems was different. Sweden and Denmark had independent hospital blood banks within hospital authorities, while in Finland the Finnish Red Cross organised a blood transfusion service on a countrywide scale.<sup>140</sup>

**31.100** In evaluating the Ortho assay, Finnish researchers looked at both material from a large prospective study done by Dr Freja Ebeling between 1987 and 1989 and local haemophilia patients.<sup>141</sup> Dr Ebeling's material was from a post-transfusion (PT) hepatitis study of 685 patients who had undergone open heart surgery. Hepatitis was diagnosed when the patient's ALT was found to exceed 2.5 times the upper normal value in one sample and 2 times the upper normal value in a second sample, and where non-viral causes could reasonably be excluded. Of the 685 coronary bypass patients, 11 developed elevated ALT levels during the six post-operative months, and were diagnosed as having acute NANB hepatitis by exclusion of non-viral causes, an incidence of infection of 1.6%. This research was subsequently written up in November 1990 in an article in *Transfusion*

<sup>139</sup> Professor Leikola's Statement [PEN.017.1957] and *Hepatitis C and blood donation* – Unofficial translation from Finnish by Juhani Leikola [PEN.017.1828] at 1828

<sup>140</sup> Day 71, pages 81–82

<sup>141</sup> *Hepatitis C and blood donation* – Unofficial translation from Finnish by Juhani Leikola [PEN.017.1828]

*Medicine*.<sup>142</sup> A secondary object of the exercise had been to obtain samples for future evaluation of possible preventive strategies, and the material was available when Ortho provided kits for evaluation in the course of the project.

**31.101** Dr Ebeling's research group applied the Ortho ELISA and a Chiron RIBA 'confirmatory' research test to the panel of 685 frozen samples already collected. Samples from the 11 patients diagnosed with post-transfusion, NANB Hepatitis were tested. Seven of them had received a blood product from an anti-HCV positive donor, on the ELISA test. A further 1029 donor samples not associated with a PT Hepatitis case in the earlier phase of the project were tested and six of these were found to be anti-HCV positive on the ELISA test. The six samples were all associated with hepatitis (raised ALT) in a patient recipient, and five of these were shown to have seroconverted (developed HCV antibodies), based on the ELISA test.

**31.102** The group published the preliminary results of this research in a letter to *The Lancet* on 21 April 1990.<sup>143</sup> The letter referred to the earlier *The Lancet* publication by Dutch researchers<sup>144</sup> and agreed with their findings that it was possible that false-positive results would be achieved with the ELISA test when screening low prevalence groups such as blood donors. In false positive cases, the kit had failed to differentiate between non-infectious and infectious blood, which would make it difficult for blood transfusion centres to decide which blood units to discard and which donors to counsel.

**31.103** On the basis of this research, however, the scientists suggested the RIBA might be helpful in differentiating between an infective and a non-infective blood donor, and that reactivity to both antigens (511 and C100) was strongly associated with infectivity.<sup>145</sup>

**31.104** Professor Leikola said that the Finnish researchers were very keen to try the new Ortho kits on the 11 patients identified in the first phase of the project as having NANB Hepatitis. Of the five who had been found to be anti-HCV negative, two had an anti-HCV positive donor. Professor Leikola commented that this demonstrated the initial (ELISA) test was not highly sensitive, and those two patients might have been positive with use of the test kits developed later.<sup>146</sup> He also observed that the level of HCV antibody fluctuated in patients. Sometimes the level was below the cut-off level for positivity and these patients were considered to be HCV negative due to that fluctuation.<sup>147</sup>

**31.105** Despite Finland having a very low prevalence of NANB Hepatitis the development of the Ortho test was welcomed there as NANB Hepatitis was still the most common infectious complication of blood transfusion. The new screening test to detect antibodies offered major advantages.<sup>148</sup>

<sup>142</sup> Ebeling et al, 'Post-transfusion hepatitis after open-heart surgery in Finland – A prospective study', *Transfusion Medicine*; 1991, 1: 103–108 [PEN.017.1777]

<sup>146</sup> Day 71, page 88

<sup>147</sup> *Ibid*, page 89

<sup>148</sup> *Ibid*, page 86

**31.106** Professor Leikola also provided the Inquiry with a translation of a memorandum he wrote in Finnish dated 10 October 1989.<sup>149</sup> It was intended for internal discussions and for the Finnish National Board of Health, which was responsible for the practical aspects of healthcare.<sup>150</sup> He commented in his memorandum: 'Thus, HCV is not responsible for all NANB hepatitis cases, and not all anti-HCV positive persons transmit this disease, but the association of HCV with NANB hepatitis is clear in Finland.'<sup>151</sup>

**31.107** The overall prevalence of HCV positivity in Finland was considered to be 0.73%. Professor Leikola commented in his memorandum that this was 'possibly slightly higher than in the rest of Scandinavia, which number is somewhat surprising considering the clinical background'.<sup>152</sup>

**31.108** The Finnish Red Cross did not require the permission of the National Board of Health to introduce screening, but did need their consent to increase the price of blood products to reflect the increased screening costs.<sup>153</sup> This proved to be a straightforward matter and consent was given by the Director General of the National Board of Health at a meeting in December 1989. The request did not have to go to a committee and permission was granted at a single meeting, in stark contrast to the situation that evolved later in the UK.<sup>154</sup>

**31.109** In the conclusion to the memorandum, Professor Leikola stated his concern at the lack of a confirmatory test, but added:

The repeatability of the screening test is, however, good. The FDA may register the test ... before the end of this year, and the American blood services will start using it as soon as possible. Testing may start soon next year also in Europe, wherever it is technically possible.<sup>155</sup>

**31.110** In his memorandum, Professor Leikola commented that whilst most hepatitis cases remained mild, they had a tendency to become chronic, and therefore, 'Since a specific test now exists that may reduce the blood inventory by as little as less than one per cent, a general screening test has to be introduced in our country to safeguard ... transfusion safety'.<sup>156</sup>

**31.111** The memorandum, from October 1989, discussed the possibility of commencing screening in Finland in the first quarter of 1990. In practical terms, the introduction of screening was relatively straightforward for Finland as there was only one, central, laboratory in the capital, Helsinki, and donations collected by mobile teams were taken there. The introduction of screening would have affected the working of only one laboratory service and would have been much simpler than having various different centres, each with its own laboratory. It would have to be a staggered start due to a limited number of testing kits and the pressures on the laboratory. The Finnish populations with higher prevalence would be screened first. 'A similar approach was used with anti-HIV screening which was started ... [in] Helsinki area donors.'<sup>157</sup> The memorandum concluded: 'Despite the costs

<sup>157</sup> *Ibid* [PEN.017.1828] at 1829

and other difficulties anti-HCV screening has to be started at the [Finnish Red Cross] Blood Service as soon as it is technically possible.<sup>158</sup>

**31.112** In oral evidence, Professor Leikola said that it was not controversial to introduce screening in a staggered fashion across the country. They had used that pattern for the introduction of anti-HIV testing, and followed the same pattern with HCV without any obvious objections.<sup>159</sup>

**31.113** Routine testing duly commenced in Finland in the beginning of February 1990 and was extended to all blood donations by 1 April of that year.<sup>160</sup>

**31.114** Dr Ebeling and colleagues proceeded to study a group of haemophilia patients in Finland.<sup>161</sup> Finland was self-sufficient in the production of clotting factors. Until 1984, small pool lyophilized cryoprecipitate (manufactured from two to eight donors) was used exclusively to treat Haemophilia A, von Willebrand's disease and Factor VIII deficiency. The total population with bleeding disorders on the central register was 230 patients. Samples were received from 137 patients, all but ten of whom had haemophilia. Surrogate tests were performed and the patients were tested with the Ortho kits. Of the study group, 68 patients (50%) from a total of 137 were anti-HCV positive, with most of the samples demonstrating strong reactivity. There was a significant association of anti-HCV with raised levels of ALT in the blood.

**31.115** The research paper on this study noted that patients with severe haemophilia had Hepatitis C antibodies significantly more often than those with milder forms of haemophilia. In addition, anti-HCV positivity was significantly more common in AHF-20 (large pool concentrate) users than in cryoprecipitate users.<sup>162</sup>

**31.116** It was noted that HCV antibodies sometimes seemed to disappear and that the percentages brought out might underestimate the number of patients with a previous HCV contact. On the other hand, the results might have been skewed in the opposite direction since patients who already knew that they had liver disease might be more willing to participate in the study.<sup>163</sup> Chiron's new RIBA confirmatory test was available to test some of the anti-HCV ELISA positive samples and proved to be very specific. It was concluded that 'false positive results were only a minor source of error among these patients'.<sup>164</sup>

**31.117** Professor Leikola was asked in oral evidence if the difficulties faced by transfusion services in dealing with 'false positives' could justify delaying the introduction of a screening test. He commented:

[I]t was very clear that as long as the number of positives ... including false positives in the primary screening is low enough so we can handle figures that are less than one per cent, and explain to the donors what is the situation ... in our opinion at the time it would not prevent introducing such a test.<sup>165</sup>

## Initial evaluation in England

**31.118** Returning to events in the UK, as noted above at paragraph 31.69 evaluation of Ortho's assay proceeded in the United Kingdom in 1989. A preliminary report of the NBTS pilot study of the first generation Ortho test, dated 23 June 1989, was presented to the third meeting of the ACVSB, on 3 July 1989. It gave summary results of tests of 3282 donations and noted that there were 22 initial reactive samples and 14 repeat reactive samples.<sup>166</sup> The report was brief and provides little useful information for present purposes.

**31.119** A second report of the pilot study, dated 10 January 1990 but relating to work undertaken in early December 1989, was presented by Dr Gunson to the fifth meeting of the ACVSB on 17 January 1990. A total of 14,133 donations had been tested by North East Thames, Trent and West Midlands RTCs.<sup>167</sup> This report assessed the practical implications of introducing the Ortho ELISA test. All participants commented that 'the test was straightforward and easy to perform'.<sup>168</sup> However difficulties with equipment and software, process problems and the marked difference in positivity rates returned, made it difficult at that stage to estimate the costs involved in screening.<sup>169</sup>

**31.120** A full report on the evaluation of the Ortho HCV ELISA test system was included in the Report on the 'Multi-Centre UK NANBH Surrogate Marker Study' dated April 1990.<sup>170</sup> The report noted that Dr Gunson had arranged a supply of test kits from Ortho sufficient to enable testing of the sera already available from the surrogate marker study.<sup>171</sup> In total 9741 samples were tested: more than 3000 at each of three centres (North London, Bristol and Manchester).<sup>172</sup> The methodology was described: 'all initially reactive sera were retested in duplicate'.<sup>173</sup> Testing was completed by early October 1989. The study found a geographical variation in the prevalence of HCV seropositivity, ranging from 1:277 for Bristol (described as 'a rural base') to 1:120 for North London (a 'metropolitan area'). There was a correlation between raised ALT and HCV seropositivity.

**31.121** The report noted:

Although from the results obtained so far it appears that the Ortho HCV ELISA has an acceptable specificity and sensitivity, these issues can not be definitively addressed as part of this evaluation, as there were no samples with well established links with NANBH tested in this study. However, this first report on screening UK donors sera for anti-HCV will serve as a basis for the future implementation of this screening test in the UK Blood Transfusion Service.<sup>174</sup>

<sup>166</sup> National Study of Surrogate NANBH Markers in Blood Donors [SNB.001.9545]

<sup>170</sup> Multi-centre UK NANBH Surrogate Marker Study [PEN.016.0075]

<sup>171</sup> Ibid [PEN.016.0075] at 0120

<sup>172</sup> Ibid [PEN.016.0075] at 0120. A total figure of 9742 donors was given at 0121 of the report, but the total number of donors from the three centres is in fact 9741.

<sup>173</sup> The Inquiry is puzzled by this statement as it appears illogical to test for a third time if the first and second tests are positive. This methodology is confirmed at [PEN.016.0075] at 0121.

<sup>174</sup> Multi-centre UK NANBH Surrogate Marker Study [PEN.016.0075] at 0123

## Initial evaluation by Dr Dow and others in Scotland

**31.122** Work proceeded on a Scottish evaluation of the Ortho assay. A preliminary report of the study was dated 5 October 1989.<sup>175</sup> The study was instigated by Professor Cash, following up his statement of interest in evaluating the anti-HCV test made at the meeting of the ACTTD on 19 May 1989. Dr Dow was a member of the team that carried out the study. He agreed that it was an ambitious study, with nine objectives.<sup>176</sup> Professor Cash had arranged to obtain the kits in June 1989. The regions each submitted samples by the start of August and testing commenced on 2 August.<sup>177</sup>

**31.123** This study had a repeat reactive rate of 0.47% overall (13/2745). There were variations within Scotland, with Aberdeen having a rate of 0.35%, Dundee a rate of 0.49%, and Glasgow a rate of 0.55%.<sup>178</sup> Dr Dow thought that the overall figure was comparable to the German figures, and considerably lower than the rate the English study found in North London.<sup>179</sup>

**31.124** Of the group of 15 patients reported to have developed post-transfusion NANB Hepatitis, Dr Dow's team found only a third (five) of the group to be anti-HCV positive.<sup>180</sup> The limited positivity in this group of 15 people was due, according to Dr Dow, to their having been tested early in their illness. It became known later that the first generation tests were not sensitive enough to pick up HCV in its early stages. They would also have failed to pick up some of the HCV genotypes that were discovered later, for example those that did not have the NS4 protein that was detected by the early Chiron test.<sup>181</sup>

**31.125** Professor Leikola's attention was drawn to this finding of the study and he agreed it was a disappointing result. He told the Inquiry that this could have been due to the way in which cases of NANB Hepatitis were identified. Further, some of the patients from the group of 15 may have had antibodies that disappeared from their blood over a prolonged period of time. He agreed also that a late appearing antibody would have been difficult to pick up if the samples had been taken early on in the progression of the disease, but he did not think that blood samples that had been frozen would yield unreliable results. In relation to patients with haemophilia, the Scottish study obtained results that can be compared with the Finnish work. Of 146 patients with haemophilia in the West of Scotland, 92 (63%) were repeatedly reactive for anti-HCV.<sup>182</sup> Dr Ebeling found 68 of 137 haemophilia patients (50%) to be anti-HCV positive: paragraph 31.114.

**31.126** Dr Dow's study also looked at sera from donors implicated in 28 cases of transmission of non-A non-B Hepatitis. This revealed only six donors as repeatedly reactive for anti-HCV. On that basis it appeared that only 21% of cases of post-transfusion NANB Hepatitis had a donor identifiable as being anti-HCV reactive. The report commented on theoretically possible explanations: individuals could lose antibody over time at one end of the scale, or at the other may not have developed anti-HCV by the time the sample was taken.<sup>183</sup>

<sup>175</sup> SNBTS Evaluation of the Ortho HCV antibody ELISA test system, Dr B Dow et al, October 1989 [SNB.006.1596]

<sup>181</sup> Day 67, pages 158–159

<sup>182</sup> Day 71, pages 100–101

<sup>183</sup> SNBTS Evaluation of the Ortho HCV antibody ELISA test system, Dr B Dow et al, October 1989 [SNB.006.1596] at 1610; Day 67, page 160

**31.127** The authors were disappointed that their study suggested that the Ortho test would have prevented only 21% of the PT-NANB Hepatitis cases. The report suggested this might be due to some cases being caused by another agent, a possible early suspicion of what came to be known of the different genotypes in existence.<sup>184</sup>

**31.128** Overall the report authors found that ‘the Ortho HCV ELISA test has been shown to have an acceptable specificity’.<sup>185</sup> The fact that the test took three hours to complete did not present difficulties to the team testing samples in Dr Dow’s laboratory.<sup>186</sup>

**31.129** The report had noted as ‘worrying’ an apparent diminution in the sensitivity of the HCV test kit as compared with the ‘Dev’ kit. Dr Dow offered an explanation for the difference between the kits at paragraph 8 of his statement:

The test kits used in the SNBTS evaluation comprised two lot numbers, DEV89038 and HCV101. The DEV kit was probably meant to be a Developmental kit (produced in smaller volumes) whilst HCV101 would have been one of the first production lot numbers.<sup>187</sup>

**31.130** In oral evidence Dr Dow added: ‘This was one of the first times we had seen a development kit being used to do an evaluation ... we [SNBTS] had actually requested a kit to evaluate it on our own behalf, rather than the company’s behalf’.<sup>188</sup> He explained that with a ‘dev’ kit the manufacturer can still make changes, which cannot subsequently be done with a ‘production batch’.<sup>189</sup>

**31.131** This was the first time the SNBTS had had access to a test for HCV. In his evidence to the Inquiry Dr Perry said that he thought it would have been too soon for this evaluation in Scotland to form the basis of a decision to use the Ortho test. It would have been seen as a Scottish contribution to a UK wide body of knowledge and would have been likely to have gone to the ACTTD for discussion.<sup>190</sup> He expected the SNBTS to be informed in their decision making by ‘wider UK and international experience of its suitability’.<sup>191</sup> The international experience was important in studying places or populations where the test was not effective. If there had been an ‘international experience where there were significant issues and problems, then clearly that would have affected our [SNBTS] decision to introduce’.<sup>192</sup>

**31.132** Professor Leikola commented in his statement that in a low prevalence country such as the UK, a very large study is required to produce a meaningful number of positive samples to test. He added in oral evidence that ‘we [Finland] had to test 15,000 blood donors that were connected with the patients, and that only gave 11 cases and six of them were positive’.<sup>193</sup>

<sup>193</sup> Day 71, page 121

**31.133** Professor Leikola wrote a review article published in 1993 entitled 'Viral Risks of Blood Transfusion'.<sup>194</sup> He commented on the identification and isolation of the first clone and the study in 1989 of the first generation assay by Harvey Alter and colleagues. The assay was reported in that study to look very promising for the diagnosis and prevention of NANB Hepatitis. The test gave positive results in a high percentage of US patients with NANB Hepatitis. European experience was less promising. There were reservations about the test. The review commented:

In subsequent studies from Europe, the percentage was, however, lower. The test was sufficiently specific to study high prevalence populations such as hepatitis patients but it gave many false positive results when applied in blood donor screening. There was no true confirmatory test since everything was dependent on only one recombinant antigen.<sup>195</sup>

### Encouragement from Ortho to conclude contracts

**31.134** Dr Gunson had indicated in his letter to Professor Cash dated 26 July 1989 that Ortho representatives were keen that he should be in contract with them for test kits.<sup>196</sup>

**31.135** On 23 August 1989 representatives of Ortho attended a meeting in London with members of both the NBTS and the SNBTS.<sup>197</sup> Dr Mitchell attended and provided a report for Professor Cash two days later.<sup>198</sup> Johnson & Johnson (Ortho) had recently released material to Abbott Laboratories under licence. In addition to a royalty, the agreement ensured that Abbott would not develop any form of test similar to Ortho's test. The letter disclosed that steps had been taken to ensure that Abbott would be at least a year behind in making a distinctive test available. Abbott would not have clinical trials done before the second half of 1990. The agreement was intended to ensure that there was no competition while Ortho built up a market share. Dr Mitchell recalled in his statement that the meeting with Ortho revealed a need to improve the company's first generation test, but Ortho was still very keen to have it introduced in the UK before it was licensed for use in its country of origin.<sup>199</sup>

**31.136** The doctors in attendance were offered kits at 1989 prices if a decision to purchase was made before the end of that year. The costs of ordering kits at 1990 prices would be higher. Ortho also offered packages combining kit sales and the provision of Ortho technology. However, Dr Mitchell advised that alternatives to the early purchase options did not have the same impact since they were purely hypothetical in terms of the next one or two years.<sup>200</sup>

**31.137** The Ortho representative was keen to know if, and how, a decision on HCV testing would be made. He was told it was subject to the advice of the ACVSB, and could not possibly be made before their meeting on 17 October 1989. In addition, it would take time for screening to be introduced as a number of other associated matters would have to be organised first, such as counselling of donors, staffing and finances. It was made clear to Ortho that if a decision to introduce screening was made, 'the UK would move

<sup>200</sup> Dr Mitchell's report [SNF.001.1449] at 1451

in unity and that there would be a simultaneous announcement, as happened with the HIV antibody testing'.<sup>201</sup> Dr Mitchell told Ortho there was 'little likelihood that the Scottish Transfusion directors would wish to have any kits ... until a decision was made'.<sup>202</sup>

**31.138** Dr Mitchell's letter of 25 August 1989 to Professor Cash ended:

I wish to stress that no decision was made that no (*sic*) Department of Health was committed to any decision in advance of the recommendations of the Advisory Committee which will make its own decision following the Rome meeting and taking account of all the scientific evidence which is being made available.<sup>203</sup>

**31.139** In the domestic Scottish context, Professor Cash was again being reminded that policy was a matter for the ACVSB.

### Scientific meetings in autumn 1989

**31.140** The Rome symposium organised by Ortho on 14–15 September 1989 provided a new focus for consideration of the Ortho ELISA. Dr Mitchell and Dr Gunson attended the symposium. Each produced reports intended in the first instance for the ACTTD meeting due to be held on 9 October that year.<sup>204</sup>

**31.141** Dr Mitchell commented in his Inquiry statement that the symposium was an important meeting. There was optimism that sufficient alterations would be made to the test to make it suitable for widespread introduction.<sup>205</sup> However, his view of the test as reflected in his report was less than enthusiastic. He emphasised the lack of a confirmatory test and the need, so long as that remained the position, for some form or set of control samples to be issued with the test to ensure that sensitivity was maintained. His view was that results should be repeated on a number of occasions at subsequent donor attendances before donors were counselled or notified. He noted that some of the issues with the test were 'obvious in the data collected from the Scottish survey'.<sup>206</sup>

**31.142** Dr Gunson's first report of the Rome meeting also commented on the lack of a confirmatory test and emphasised that such a test for seropositive blood donors was urgently needed.<sup>207</sup> Chiron's proposed RIBA test had limitations but would resolve some false results. The ACTTD was asked to approve in principle the routine testing of blood donations for anti-HCV and to request the National Directors in England and Scotland to arrange for the simultaneous introduction of the tests at an appropriate time when a policy had been defined for handling the seropositive donors.<sup>208</sup>

**31.143** In the interval between the Rome meeting and 9 October, the British Blood Transfusion Society met in Durham. On the last day of the meeting (around 22 September) doctors from the NBTS and the SNBTS<sup>209</sup> met with Ortho representatives. Dr Mitchell

<sup>206</sup> Dr Mitchell's report [SNB.001.8678] at 8681. The reference was to the study by Dr Dow and others – see paragraph 31.122 onwards

<sup>207</sup> Dr Gunson's report [SNB.006.1456]

<sup>208</sup> Ibid [SNB.006.1456] at 1460

<sup>209</sup> Dr Mitchell, Mr A Barr (SNBTS), Drs Gunson, Contreras and Barbara (NBTS)

produced a note of the meeting.<sup>210</sup> He reported that Dr Gunson had indicated that, in his view, it was likely that the ACTTD would recommend to the ACVSB on 6 November that screening should be introduced in the 1990/91 financial year, and thus would commence some time after 1 April 1990. It was anticipated that the meeting of the ACTTD on 9 October would finalise the details of the report or reports to the ACVSB. Ortho had indicated that a lead-in time of at least 90 days would be required but, given that period, Ortho could supply kits on a regular basis and have at least two different batches in centres at any one time. Dr Mitchell recorded that Dr Contreras was hesitant at the speed of introduction proposed, especially since no account had been taken of how donor counselling would be carried out. She considered that some of the data presented at Rome and elsewhere were imprecise and that there were many grey areas. Nevertheless, there was recognition that the implementation of the European Commission requirements for blood and blood products was imminent (in 1992) and that member state governments might have to 'subscribe to ... "State of the Art" technology'.<sup>211</sup> By this stage (October 1989) the Chiron/Ortho test was being used in a large number of blood transfusion laboratories, as well as many virology diagnostic laboratories, throughout the world, albeit no country had yet introduced the test for routine screening of blood donors.

**31.144** The ACTTD duly met on 9 October 1989, its third meeting.<sup>212</sup> Members were told that the ACVSB had requested a briefing paper on policy regarding anti-HCV testing of blood donors. The committee considered the two papers, written by Drs Gunson and Mitchell. In addition, a report from North West Thames RTC on surrogate markers for NANB post-transfusion hepatitis was discussed. It was agreed Dr Gunson's paper should be amended for presentation to the ACVSB, to incorporate information from the paper prepared by Dr Mitchell, and the North West Thames report, and to reflect a number of textual amendments proposed by the committee.

**31.145** Dr Gunson duly amended his report for presentation to the ACVSB.<sup>213</sup> The main recommendation in Dr Gunson's amended report was that: 'Routine screening of blood donations for anti-HCV should be introduced when practical .... The committee [ACVSB] is asked to approve the routine testing of blood donations for anti-HCV in principle'. The recommendation was subject to the following conditions:

- There should be a defined policy for counselling and management of seropositive donors.
- A confirmatory test for seropositive blood donors was urgently needed. The RIBA put forward by Chiron had limitations.
- The routine use of the test should not commence until an FDA licence was in place.
- Pilot studies involving routine prospective use of the test in RTCs on freshly collected samples (as opposed to library frozen/thawed samples) should be established as soon as possible.

---

<sup>210</sup> Meeting note [SNB.002.4553]. The note and the meeting are further described at paragraph 9.145 of the Preliminary Report.

<sup>211</sup> Ibid [SNB.002.4553] at 4554

<sup>212</sup> Meeting minutes [MIS.001.0016]

<sup>213</sup> The report is part of the papers relating to the ACVSB meeting [SNF.001.1383] at 1405-06

**31.146** The fourth meeting of the ACVSB took place on 6 November 1989.<sup>214</sup> Dr Gunson spoke to his paper and told the committee that the ACTTD recommended that routine screening should be introduced only after a confirmatory test became available, after the FDA had approved the test and after urgent pilot studies had been carried out in this country to consider the feasibility of using the kits on freshly collected samples and to assess how they could be integrated into normal working practices.<sup>215</sup> The ACTTD considered that routine testing for anti-HCV would reduce the incidence of NANB Hepatitis. Estimates of the extent of the reduction ranged from 20–60%.

**31.147** The Chairman, Dr Metters, summed up the views of the ACVSB. They broadly took on board the recommendations of the ACTTD, but stopped short of approving the introduction of routine testing in principle. The feeling of the committee was that while the test represented a major step forward, the committee needed to know a great deal more about it, and there was a need for a confirmatory test. The ACVSB would support the general introduction of the test if the FDA approved it and the pilot trials showed the test to be feasible and non-problematic. Pilot studies would be carried out in Brentwood, Birmingham and Sheffield, of the feasibility of adding the kits to routine practice.<sup>216</sup>

**31.148** Dr Perry (who had not attended the meeting) commented in his Inquiry statement that, upon reading the documents, he thought Dr Gunson was trying to convey to the ACVSB the views of Transfusion Directors that the implementation of testing was inevitable. Dr Gunson was recommending to the ACTTD that the test was effective and should be taken seriously and ultimately introduced.<sup>217</sup> The minutes of the ACVSB recorded ‘a much more cautious position’.<sup>218</sup> According to Dr Perry this may have been due to the views of influential members such as Professor Zuckerman, Professor Tedder and Dr Metters.<sup>219</sup> He recalled that the ACVSB Chairman, and some of the expert Virologists, considered Dr Gunson’s approach to be ‘premature’.<sup>220</sup>

**31.149** In his written statement Professor Leikola commented that he thought the outcome of the meeting of the ACVSB noted above was ‘quite reasonable’.<sup>221</sup> In oral evidence, he qualified that statement. He said that he was a little surprised to see no clear cut decision to implement screening of donors. There was a recommendation of sorts and it was considered useful to have the test. But he explained that at this stage the FDA had not even licensed it for export, and therefore everything was on a preliminary and research level. It was ‘sort of natural that the committee was in general ... in a positive mood towards a future screening by this test but decided then to wait and see the developments and make a definitive decision later on’.<sup>222</sup> The minutes were not clear as to the committee’s commitment, but he understood the minutes to indicate that once FDA approval was given, and there was a confirmatory test, the decision would be positive if there were not any major problems.<sup>223</sup> On his understanding of the decision, that there were these automatic triggers, he thought the outcome of the meeting was reasonable.<sup>224</sup>

<sup>222</sup> Day 71, page 127

<sup>223</sup> Ibid, pages 128–129

<sup>224</sup> Ibid, page 128

**31.150** Dr Gunson reported the cautious views of the ACVSB to the next meeting of the ACTTD on 22 November 1989.<sup>225</sup> Dr Perry commented in oral evidence that ‘it was probably an outcome that was predicted ... everyone knew at that point that the UK was not ready to implement HCV testing’.<sup>226</sup>

**31.151** It appeared to Dr Perry that it was typical of the cautious approach of a government department not to make a policy decision until it was proved to be deliverable and all its consequences were known.<sup>227</sup> He thought the policy makers in the government were naturally more cautious than the practitioners who delivered the services would have wanted. In his view, that conflict would always be present.<sup>228</sup> Professor Leikola appeared to be in agreement with this view in his initial statement to the Inquiry on this topic. In relation to this period, Professor Leikola observed that opinion was divided between the views of the practical transfusionists and the academics.<sup>229</sup> He thought that Dr Gunson was a practical transfusionist.<sup>230</sup>

### Export permit and ‘confirmatory test’ in November 1989

**31.152** As appears from the discussion so far, one of the factors which featured in discussions of the possible introduction of screening in the UK over the period 1989 to 1990 was whether the FDA in the USA would approve the test for use there. In his statement Dr Perry expressed the view that waiting for the FDA to license the test kit was intended to provide the UK with evidence of satisfactory performance in the absence of a formal UK evaluation. There was no similar licensing regime in Britain. It would have been embarrassing if the test had been introduced in the UK and the FDA then refused to license it for use within the USA. He thought Ortho was unlikely to have retained their earlier export licence if the FDA had rejected the application to ‘license’ it in the USA.<sup>231</sup> In his statement, Dr Dow commented that:

The FDA were notoriously strict controllers of the quality of test kit systems. To be informed that a kit was FDA-approved meant that the manufacturers were expected to keep the same sensitivity and specificity over all lots that were produced, thus ensuring that the kits were robust quality products.<sup>232</sup>

**31.153** By way of contrast, a different, more casual, attitude to FDA licensing was reflected in a Department of Health memorandum dated 30 January 1985 relating to the introduction of screening for HIV.<sup>233</sup> The memorandum, entitled: ‘Evaluation of HTLV III kits: Some thoughts for consideration’, noted that ‘USA firms will have obtained *some sort* of FDA clearance before marketing in the UK starts’.<sup>234</sup> A different DoH memorandum dated 21 January 1985 stated: ‘We also discussed whether or not any reference should be made to tests not being accepted in the UK unless they had FDA approval ... FDA approval was in any case *one* of the factors to be considered in any evaluation’.<sup>235</sup> Dr Dow’s view is preferred: as a scientist with practical experience of the way the system operated, he

<sup>235</sup> Memo [DHF.002.7101] emphasis added

had direct knowledge of the working of the FDA. The reference to 'some sort of FDA clearance' indicates a lack of understanding on the part of the official.<sup>236</sup>

**31.154** Ortho Diagnostic Systems Ltd (the UK Company) wrote to Professor Cash on 27 November 1989, intimating that an export permit had been approved by the FDA for the Ortho ELISA test.<sup>237</sup> This meant Ortho could supply their product labelled for 'In vitro diagnostic use' instead of 'Research use only'. Dr Perry agreed in oral evidence that this was an optimistic early signal that the FDA would license the test for routine use within the USA.<sup>238</sup>

**31.155** On the same day, Ortho Diagnostic Systems Inc, New Jersey, faxed a second letter to Professor Cash, announcing that they had 'just completed production of a small number of prototype confirmatory tests in [their] RIBA (Immunoblot) format'.<sup>239</sup> The letter provided some details of the test format. Ortho hoped at the time of writing to introduce this confirmatory test in the first quarter of 1990. The American company intimated that C-100 antigen (the HCV protein) could not be made available to investigators for testing at that stage. The faxed letter indicated that three separate bands of antigen were used in the RIBA.

**31.156** The letters did not indicate that Ortho's ELISA had been approved by the FDA for use in the USA. One could not infer that the FDA had completed by this stage the investigations necessary for domestic purposes. However, it would be an over-cynical view to suggest that the FDA would release for use by the rest of the world a test about which it had material concerns. Dr Mitchell's report on the Rome Symposium referred to above noted that Ortho anticipated FDA licensing according to 'the agreed timetable'. The export permit was an encouraging development. It was sufficient for Finland and some other European countries to introduce routine testing in early 1990.

**31.157** It appears to be clear that information about the RIBA confirmatory test was published at the Rome symposium discussed above. Dr Mitchell appended to his report of the symposium a circular distributed by Ortho giving preliminary information on a RIBA confirmatory test then currently under evaluation.<sup>240</sup> The information was the same as set out in the faxed letter to Professor Cash on 27 November.

**31.158** Dr McClelland was asked in oral evidence about the usefulness of the first RIBA as a confirmatory test. He commented that there was a general acceptance amongst most virologists that the immunoblot tests such as the RIBA and Western Blot 'were a useful addition and provided valuable extra information to interpret the result of a positive ELISA test'.<sup>241</sup>

**31.159** He commented further in his statement:

The advantage of RIBA or WB is that with these methods a sample that gives a positive reaction with a screening test can be further analysed to show the reaction of the sample with different components of the virus, and can give additional help in distinguishing a false positive from a true positive result.<sup>242</sup>

<sup>236</sup> Professor Cash shared Dr Dow's view of the rigour of FDA assessment – see paragraph 31.210

<sup>237</sup> Ortho letter [SNB.006.1560]. At the time of writing the Preliminary Report it was known that this and the next letter [SNB.006.1561] had been written and copies were obtained later. See paragraph 9.162 of the Preliminary Report.

<sup>238</sup> Day 68, page 58

<sup>239</sup> Fax [SNB.006.1561]

<sup>240</sup> Circular [SNB.002.4555]

<sup>241</sup> Day 69, page 23

<sup>242</sup> Dr McClelland's Statement [PEN.017.2491] at 2497

**31.160** Dr McClelland thought the RIBA represented added value and information.<sup>243</sup> He added, however, that some groups of virologists, notably one led by Professor Tedder, felt the RIBA tests 'were a waste of time'.<sup>244</sup>

**31.161** Dr Dow had his own concerns about the value of the RIBA as a 'confirmatory' test. He commented in his statement:

[T]he first generation RIBA was based on only two specific HCV recombinant proteins which were both products of the same area of the genome (the non-structural (NS) 4 region). As both these recombinant proteins were the coating materials for the solid phase ELISA microwell, it was predicted that the same cross-reacting antibodies would produce (false positive) reactives in both ELISA and RIBA systems.<sup>245</sup>

### **The end of 1989: comment**

**31.162** In the course of 1989, the NBTS and the SNBTS each obtained test kits from Ortho for evaluation. There is no evidence to suggest that they could have been obtained earlier. Dr Gunson and Professor Cash agreed that the two services should act in close collaboration and envisaged difficulties if either should introduce the test unilaterally. Each proceeded with evaluation.

**31.163** By the end of August 1989, UK commentators appear to have formed a generally favourable view of the first generation Ortho test, but there were still reservations. Drs Contreras and Barbara were concerned about the predictive value of the test in low HCV prevalence populations, such as UK blood donors. Professor Cash, Dr McClelland and others thought that without a confirmatory test there would be serious problems for the Blood Transfusion Services in differentiating between true and false positives. There was concern that repeat and supplementary testing based on a common antigen source – both in initial screening kits and in the early RIBA format – failed to provide the confirmation required.

**31.164** The preliminary report of the NBTS pilot study was available in June 1989, with a second report in January 1990. As finally reported, in April 1990,<sup>246</sup> the study found that the first generation Ortho HCV ELISA tests appeared to have an acceptable level of specificity and sensitivity, albeit these issues could not be addressed definitively as part of the evaluation. There were no samples with well established links with NANB Hepatitis available to be tested.

**31.165** While Dr Dow's study in October 1989 reported disappointing results in a group of 15 patients 'known' to be positive for transfusion-transmitted NANB Hepatitis, the study nonetheless concluded that the Ortho test had an acceptable level of specificity. There is no doubt, on Professor Cash's evidence, that the Glasgow laboratories were the most experienced researchers in this area in Scotland at the time. They were the right people to carry out the assessment of the Ortho ELISA kits.

**31.166** As discussed above, a very different approach was adopted in Finland. The Finnish National Board of Health was open to advice from the Finnish Red Cross. The

<sup>244</sup> Ibid, page 24

<sup>245</sup> Dr Dow's Statement [PEN.017.1915] at 1919

<sup>246</sup> Report of Multi-centre UK NANBH Surrogate Marker Study [PEN.016.0075]

Red Cross did not need consent for the introduction of tests, but did need consent to raise prices: the consent was easily obtained. Professor Leikola was concerned at the lack of a confirmatory test but thought that, in light of the risk of chronic illness, since there was a test it had to be introduced. It was duly introduced in February 1990. Local circumstances are important. What was acceptable in Finland would not necessarily have been acceptable in the UK. Competent experts may reasonably take different views.

**31.167** The Inquiry accepts that there would have been difficulties in introducing the Chiron test kit for routine use at the end of 1989. It was not licensed by the FDA for export until November 1989, the need for a confirmatory test had not been met and pilot testing in the UK was thought necessary. It is of concern, however, that there was no firm intention to recommend screening once these conditions had been met. On 9 October 1989 the ACTTD had Dr Gunson's report, agreed amendments, and was prepared to submit it to the ACVSB. From the terms of the amended report, the ACVSB was fully informed when it met on 6 November as to the conditions that had to be met for the introduction of the test in the UK. On the information available, FDA approval, at least for export, could have been seen to be imminent after the Rome meeting. The ACVSB appeared unwilling to go further than offering support for 'general introduction' if the three conditions were met, and to developing an economic case for the DoH to fund routine use of the test. The date fixed for the next meeting of the committee was 17 January 1990. It would be six weeks before the ACVSB was expected to resume consideration of the issue. Professor Leikola's surprise that there was no firm decision on 6 November is understandable. Associated with the lack of a firm intention to introduce routine screening, was the decision that there was no case for introducing surrogate tests for NANB Hepatitis. In combination, the decisions put action on hold over the end of 1989 and early 1990.

### Events of 1990

**31.168** The ACVSB met for the fifth time on 17 January 1990.<sup>247</sup> The pilot study agreed to in November 1989 had been completed and approximately 5000 tests had been conducted at each of three centres, Brentwood, Birmingham and Sheffield. The percentage of repeatedly reactive donors at these centres was, respectively, 0.61%, 0.28% and 0.18%.<sup>248</sup>

**31.169** There was a full discussion of NANB Hepatitis and the issue of HCV testing. By now the FDA had approved the Ortho ELISA for export. Professor Zuckerman proved to be a powerful voice at that meeting. He recommended a delay in the introduction of testing until the FDA had approved the test for use in the USA and thought the FDA was unlikely to license the test in the absence of a confirmatory test (although by now information about the forthcoming Chiron RIBA confirmatory test was quite widely known).<sup>249</sup>

**31.170** It was also the understanding of Dr Rotblat of the DoH that the FDA was unlikely to approve the test at this stage. If the minutes are reliable, Dr Gunson did not comment that an export licence had already been granted. However, Professor Zuckerman added in a letter considered by the ACVSB that 'the introduction of screening could not be delayed much beyond FDA approval'.<sup>250</sup> He noted in his letter that test kits were being

developed by other manufacturers and added at the meeting that the committee should keep an open mind on other, newer test kits, which should be available within the next 12 months.<sup>251</sup>

**31.171** The minutes record mixed views from others in attendance. For example, Professor Tedder was reluctant to make recommendations at that time as so little was known about the virus and its antibody markers, but Dr Mortimer was keen to introduce screening and considered that if routine use of the test began there should soon be a better test to move on to.<sup>252</sup> Dr Mitchell felt that it was possible to deal with donors who tested positive, without causing undue alarm. Dr Gunson explained that the transfusion services were under a great deal of pressure, not just from Ortho but from the press and, increasingly, from clinicians in the field. He felt that 'each centre must now consider how to set up the test and what extra resources they would need to do so'. In oral testimony Dr Perry denied there were widely divergent opinions at that meeting, just simply various views about different aspects of testing, according to individual areas of expertise.<sup>253</sup> Cost was an important consideration, but a strict cost/benefit analysis was never a topic for discussion at the ACVSB.<sup>254</sup>

**31.172** Dr Perry told the Inquiry the ACVSB members did not vote.<sup>255</sup> As a matter of procedure, each member had to express a personal view and it was for the Chairman to elicit such consensus as could be identified. The Chairman, Dr Metters, would summarise the main views of the committee and members were invited to agree or disagree with him.<sup>256</sup> At this stage there was insufficient consensus to form a definite recommendation or decision.<sup>257</sup> There was an emphasis on understanding scientific principles and a desire to be sure the test was appropriate before a policy could be announced.<sup>258</sup>

**31.173** The general consensus of this meeting was summed up by the Chairman: routine testing was not to be introduced in advance of the FDA decision and not enough was known scientifically at that time as yet.<sup>259</sup> After further discussion the committee agreed that the costs of introducing testing in each region should be looked at now, Professor Zuckerman's figures on the number of possible cases of chronic liver disease that could be prevented by the introduction of testing should be further refined and the committee could give no further scientific advice at that point, but would discuss the matter further at the next meeting (in April) which would be after the International Hepatitis Meeting in Houston. There was no clear recommendation that testing should be introduced as soon as the FDA had given the green light to the US blood banks.<sup>260</sup>

**31.174** The minutes of the meeting recorded Dr Metters as saying that 'funding would have to be found from the existing ... allocation'.<sup>261</sup> The minute clearly recorded Dr Metters' understanding of UK Government policy: there would be no new money for screening and health boards (at least in England and Wales) would have to find the necessary funds within their existing budgets.

<sup>260</sup> Professor Leikola's Statement [PEN.017.1961]

<sup>261</sup> Meeting Minutes & Associated Documents [SNF.001.1491] at 1496

**31.175** Dr Perry's note of the fifth meeting of the ACVSB also recorded that:

[The] majority view was that [there was] sufficient evidence of test positive/infectivity correlation to justify implementation – overriding factor was question of product liability .... Agreed not to introduce test in advance of FDA approval but very compelling reasons to implement quickly following U.S. decision.<sup>262</sup>

**31.176** It was put to him in oral evidence that his note suggested that a 'fly on the wall' at the meeting, ie a completely independent observer, would have concluded that the committee was in favour of introducing the test, the deciding factor being the question of product liability. In response Dr Perry agreed that is how it read, and that while his hastily written note did not contain a full record all of the arguments put forward for and against the introduction of testing, it would have reflected at least the 'mood' of the committee as detected by him.<sup>263</sup> Notwithstanding his reservations about his note, there is no reason to think that what Dr Perry recorded failed to reflect the discussion: yet the absence of any reference in the minutes of the meeting to product liability as a factor (when Dr Perry's note suggests it was the overriding factor in favour of implementation) raises a question whether the formal minutes fully reflect the discussion that took place.

**31.177** On 16 March 1990 the ACTTD met for the fifth time.<sup>264</sup> It noted that the ACVSB had at its last meeting deferred the decision to introduce routine screening of blood donations for anti-HCV.

#### **Discussion at April meeting: change of tone since January?**

**31.178** The sixth meeting of the ACVSB on 24 April 1990<sup>265</sup> was dominated by discussion of HCV testing. The meeting followed two symposia. One, sponsored by Ortho, was held in London in February 1990. The other, sponsored by Abbott, was held in Chicago on the same day as the Ortho symposium. Dr Andrzej Rejman (Senior Medical Officer at the DoH and member of the ACVSB Secretariat) attended the Ortho symposium. Dr Mitchell and Professor Zuckerman attended and reported to the ACVSB on the Abbott conference. Reports of the proceedings appear to have had a significant influence on the committee. In particular, one of the factors that appear, at least in retrospect, to have influenced the decision of the committee on HCV testing was the report of the Ortho symposium.

#### *The Ortho symposium*

**31.179** Papers for the ACVSB meeting in April, circulated in advance, included documents apparently assembled by Dr Rejman and relating to the Ortho symposium. The papers included a brief synopsis of the contribution of each of a number of speakers, together with an abstract of the presentation of each speaker to the symposium. The bundle was prefaced with the secretariat's impressions of the event.<sup>266</sup>

**31.180** At the invitation of the Chairman, Dr Rejman opened the discussion on the Ortho symposium by expressing the view that 'the overall impression was that the test was not sensitive or specific enough for reliable testing' and that a confirmatory test and more information about the significance of positive results were needed before the Ortho test could be used for the routine screening of healthy donors. Dr Mortimer is reported to

<sup>266</sup> Report on Ortho HCV Symposium [SNF.001.1628]

have said at the ACVSB meeting that there was an underlying feeling against screening because of the lack of confirmation tests, but that:

He thought confirmatory testing would become available within a reasonable time and that the routine screening of blood donors could not be delayed for a long time.<sup>267</sup>

**31.181** Professor Zuckerman, who again was a powerful voice at the meeting, echoed disappointment at the outcome of the symposium. He said that the non-specificity and sensitivity of the Chiron/Ortho test had been the main talking points at the London symposium.<sup>268</sup>

**31.182** Dr Barbara had presented a paper to the symposium on 'HCV and Blood Transfusion Service'.<sup>269</sup> In his view, the ELISA test was a 'turning point of years of frustrating search' for the agent of NANB Hepatitis, but left many important questions for the transfusion service, which were being researched. In particular, his abstract stated that 'the predictive value of a positive anti-HCV result in a blood donor in relation to transmissibility of NANB Hepatitis is still under active study'.<sup>270</sup> The imminent availability of supplementary tests from Ortho was welcome and was expected to reveal relevant information. Dr Barbara had also commented in his paper that Chiron had recently described cDNA polymerase chain reaction for HCV RNA which would shed some light on the infectivity of anti-HCV positive donors.<sup>271</sup>

**31.183** Dr Rejman's note of Dr Barbara's presentation recorded concern about how to address the issue of 'false-positive' donors. It struck a note of caution in the summary: 'Several "HCVpos[itive]" donors have not transmitted either transaminitis or HCV. How can "false positives" be addressed, this is of great concern?'.<sup>272</sup>

**31.184** Dame Sheila Sherlock in her 'HCV and Autoimmunity' abstract presented at the London symposium, noted that, in that context, 'Clearly the relation of anti HCV to actual hepatitis C disease must be clarified. Better tests are needed for the hepatitis C virus'.<sup>273</sup>

**31.185** The summary of the paper by Dr G Dusheiko entitled 'Hospital diagnosis of HCV' concluded: 'The Ortho test is in its infancy, it is not infallible and there are no QC [quality control] panels available to check its reactivity'.<sup>274</sup>

**31.186** The notes of Dr Mortimer's presentation recorded further caution: 'There are no confirmatory tests at present .... The Ortho HCV [antibody] is a late [antibody], appearing 130-150 days post-transfusion .... Presence of [antibody] does not mean/imply infectivity'.<sup>275</sup> Dr Mortimer had stated in his short abstract that the Chiron/Ortho test 'detects an antibody thought to be present in many who have been infected with HCV'.<sup>276</sup>

<sup>276</sup> Report on Ortho HCV Symposium [SNF.001.1628] at 1643

*Ortho symposium: a contrasting view*

**31.187** Following his attendance at the Ortho symposium, Dr Frank Boulton (Deputy Director of the Edinburgh Blood Transfusion Centre) wrote a letter on 21 February 1990 to Professor Cash,<sup>277</sup> Dr Boulton felt very strongly that the screening of donors should be introduced at the earliest opportunity. The test was not perfect, but there was little doubt people had contracted HCV as a result of transfusions which they would not have received if there had been screening for HCV antibodies. He was concerned that the SNBTS would face future litigation from people infected with HCV from blood that could have been screened.

**31.188** Dr Boulton had, in addition to a letter, composed a five page report of the material presented at the symposium.<sup>278</sup>

**31.189** The contrast between the negative tone of Dr Rejman's comments and Dr Boulton's observations raises issues, reflected in Dr Perry's evidence, as to the part played in the discussion by academic virologists, and about the role of the secretariat.<sup>279</sup> Dr Perry suggested that, at this point 'the best [was becoming] the enemy of the good'.<sup>280</sup>

**31.190** Professor Cash said in oral evidence that he agreed with Dr Boulton's view. He had been satisfied with the results of the first study done in Glasgow. The specificity of the Chiron/Ortho test was acceptable. He thought at the time that no test for HCV was going to be perfect and 'something was better than nothing'.<sup>281</sup>

*The Abbott symposium*

**31.191** As noted above, Dr Mitchell and Professor Zuckerman reported to the ACVSB on a conference held by Abbott in Chicago on the same day as the Ortho symposium. Dr Mitchell brought back a list of guidelines dated 8 February 1990, issued by the American Association of Blood Banks (AABB), the American Red Cross and the Council of Community Blood Centres.<sup>282</sup> Despite the absence of FDA licensing, these organisations were willing to issue guidelines for screening for anti-HCV. They directed that screening should commence as soon as FDA approval had been given. Professor Leikola thought they must have had some knowledge that the RIBA confirmatory test was coming, and consequently the FDA approval would not be far behind it.<sup>283</sup>

**31.192** Professor Cash sent a copy of the guidelines to Dr McIntyre at the SHHD with a letter dated 19 February 1990.<sup>284</sup> According to a manuscript note on the letter dated 5 March 1990 (written by Mr Roderick Angus, SHHD<sup>285</sup>), Dr McIntyre copied the guidelines to Dr Pickles of the DoH in London. Mr Angus went on to note that he had spoken to a civil servant in the DoH who told him the press statement had: 'stirred up a hornets nest. She asked for further info on it, in particular was the statement issued'.<sup>286</sup>

<sup>277</sup> Letter [SNB.014.1644]

<sup>278</sup> Report of HCV Symposium Organised by Ortho [SNB.014.1645]

<sup>279</sup> A note of the meeting prepared by Dr Perry [SNF.001.1710] at 1711, reported that discussion on HCV testing was 'dominated by reports and discussions by academic virologists!'

<sup>281</sup> Day 72, page 137

<sup>282</sup> Guidelines for Planning the Implementation of Anti-HCV Testing of Blood and Components for Transfusion [SNB.001.9825]

<sup>283</sup> Day 71, page 134

<sup>284</sup> Letter [SGH.002.8477]

<sup>285</sup> Confirmed by Mr Angus in his Statement [PEN.017.2084] at 2086

<sup>286</sup> Letter [SGH.002.8477]

**31.193** Mr Angus himself commented in his Inquiry statement that he could not recall the specific circumstances but thought:

[I]t would be reflecting the unexpectedness of the American announcement and the expectation of calls for the immediate introduction of similar testing in the UK. The reference to having “stirred up a hornet’s nest” reflects that unanticipated nature of the announcement rather than any anger felt by anyone.<sup>287</sup>

**31.194** Dr Mitchell thought Dr McIntyre’s communication with the DoH indicated that there were significant developments on their way and, once the main impediment had been removed, screening should be introduced in the UK.<sup>288</sup>

**31.195** Professor Cash in his oral testimony did not disagree with the suggestion put to him that upsetting the ‘hornet’s nest’ was caused by bringing into very sharp focus the likelihood of the USA introducing screening in early course, and this being at odds with the seemingly slow progress in the UK.<sup>289</sup>

**31.196** However, that apart, information about the AABB guidelines was clearly circulating within the SHHD and the DoH before the ACVSB meeting.

#### *The ACVSB minutes*

**31.197** At the ACVSB meeting itself, Professor Zuckerman stressed that the major cause of PTH was the NANB virus. He commented on the Abbott symposium. He noted that there was evidence of different ‘strains’ of the Hepatitis C virus which would have serious implications for diagnosis and the development of vaccines. He commented on the findings of US studies showing that the predictive level of anti-HCV positivity for infection was about 77% and recommending that positive donors should be deferred. He also reported the results of testing Abbott’s RIBA test and remarked on his view that the RIBA was not good enough to use routinely as a confirmatory test. He thought that the conference had been rather promotional in character.<sup>290</sup>

**31.198** Professor Tedder tabled a paper on the use of a modified PCR assay for the detection of HCV sequences in anti-C100 positive donations.<sup>291</sup> The PCR test, unlike the ELISA and RIBA tests, detected Hepatitis C antigen, rather than antibody. Study had shown the method to be a useful confirmatory test for detecting virus particles in the bloodstream. The assay was not, in its present form, suitable for mass screening needs, but recent modifications of PCR technology indicated its potential for large scale-testing.

**31.199** Dr Mitchell reported on proceedings at the symposium hosted by Abbott.<sup>292</sup> He said that the vast majority of Hepatitis C cases were not transfusion-related. With high-risk groups, anti-HCV positivity was high, but in a cross section of blood donors concordance was much lower. As discussed above, he reported that the AABB had directed that testing for anti-HCV should be introduced as soon as FDA approval had been given.

<sup>287</sup> Mr Angus’ Statement [PEN.017.2084] at 2086

<sup>288</sup> Day 69, page 171

<sup>289</sup> Day 72, page 135

<sup>290</sup> Meeting Minutes [SNB.001.9761] at 9763; Professor Zuckerman’s notes from the International Viral Hepatitis and Liver Disease Conference [SNF.001.1700]

<sup>291</sup> The paper was later published in *The Lancet*, 16 June 1990 [LIT.001.0263]

<sup>292</sup> Meeting Minutes [SNB.001.9761] at 9762

**31.200** Before opening the subject of testing to general discussion, the Chairman of the ACVSB, Dr Metters, reported that France, Belgium and Luxembourg had introduced routine screening of blood for HCV antibody. Italy had introduced the test on a voluntary basis. He went on to remark that, from the reports, the science seemed to have advanced little from the time of the previous meeting of the committee.<sup>293</sup> There were still questions whether the anti-HCV test was reliable and a useful step forward or whether it still created too many problems at that stage.

**31.201** After further contributions, the Chairman summed up the discussion:

- there was inadequate scientific data to support the introduction of the Ortho test for routine screening;
- a confirmatory test was needed which could be used in the RTCs and not just specialised laboratories;
- the FDA had not yet approved the test and it would be reassuring if the regulatory authority in the country of origin had done so;
- there was a need to learn more about the donor panels and the significance of positive reaction to the hepatitis C antibody test;
- a prospective study involving 25–50,000 donors would generate sufficient positives for confirmatory testing.<sup>294</sup>

**31.202** Dr Metters was concerned that there should be no confusion about the respective roles of the ACVSB and the ACTTD. He said:

The ACVSB advised Ministers on the virological safety of blood. The UKBTS Committee considered the operational implications of policy, gave the Department advice on safeguards against non-viral threats to blood and contributed to the advice on viral safety through input to the ACVSB.<sup>295</sup>

**31.203** The DCMO intended to write to Dr Gunson as Chair of the ACTTD in order to agree their respective roles. Dr Gunson was noted as confirming that he shared Dr Metters' view of the roles and thought there was no conflict between the committees. Whatever may have been the basis for the Chairman's concerns, the minute is further evidence that the decision whether to introduce HCV testing of blood donations was a matter of policy, to be decided by the government, on the basis of the expert advice of the ACVSB, rather than being a matter for the blood transfusion services. It is a matter for comment that, in emphasising the subordinate role of the ACTTD, Dr Metters implicitly accepted that it was the unqualified responsibility of the ACVSB to provide the government with the scientific advice required for formulating policy in this area.

**31.204** Dr Perry said in his Inquiry statement that he could not recollect the DCMO providing an explanation at the time of the need for his statement of intent. He speculated that 'the statement was intended to be an assertion of the authority of ACVSB to make policy recommendations ... and that ACTTD was subordinate to this authority'.<sup>296</sup> The question, however, is why such an assertion was required. It appears that, by this time, the respective roles of the ACVSB and the ACTTD had become an issue between them.

<sup>295</sup> Ibid [SNB.001.9761] at 9765

<sup>296</sup> Dr Perry's Statement [PEN.017.2108] at 2109

**31.205** Dr McIntyre produced a note of the meeting for the SHHD that reflected the negative conclusions of the committee but confusingly recorded that 100,000 donors were contemplated for the proposed study.<sup>297</sup> Rather than proceeding to recommend that testing should be introduced, with or without conditions, the committee decided to initiate a large prospective study to investigate the significance of a positive test result and a sub-group was set up to prepare a protocol.<sup>298</sup> It was to include Dr Gunson and Dr Mitchell.

**31.206** Dr Perry reported back to Professor Cash in a personal note.<sup>299</sup> It was intended to convey his view of the meeting to a selected audience, whilst still being bound by the rules of confidentiality. Both he and Dr Gunson had felt there was sufficient data for testing to be introduced. He denied in oral evidence that he was suggesting in his note that the blood transfusion services were ready to introduce the test in April 1990. Rather, there was enough information for the government to make a policy decision that the test could, and should, be introduced in future. Other Western countries were beginning to introduce it and he thought the UK could adopt a more positive approach rather than hanging back and waiting for the science to improve.<sup>300</sup> He told the Inquiry in his statement that he shared this feeling with Dr Gunson.<sup>301</sup> He recalled this meeting as being the first point at which he thought there was information available to make a good case for the introduction of testing.<sup>302</sup>

**31.207** However, the outcome was that the meeting of the ACVSB on 24 April 1990 did not recommend the introduction of screening. Professor Leikola said in oral evidence about the material from the Ortho symposium:

It's very natural that in that kind of symposium, the investigators, they are not marketing people for this commercial manufacturer, but they want to have a critical approach to these tests and I think it's natural that they emphasise the fact that they have found, you know, that it's not a perfect test and so on. So much are not detected and so many are false positives also. But to draw this conclusion that it should not be introduced at that time, I think I, at least, couldn't make out of these abstracts.<sup>303</sup>

**31.208** With regard to Dr Rejman's comment that the test was not 'sensitive or specific enough for reliable testing', Professor Leikola pointed out in oral testimony that the tests were considered good enough by the Finnish authorities for screening to have been introduced in early 1990.<sup>304</sup> Professor Leikola commented in his Inquiry statement that the 'change of attitude of the ACVSB between January and late April was remarkable'. He added: 'The reservations as to routine screening had meanwhile grown'.<sup>305</sup>

<sup>305</sup> Professor Leikola's Statement [PEN.017.1961] at 1962

### FDA approval May 1990

**31.209** On 2 May 1990, a week after the ACVSB meeting, the US FDA licensed the Chiron/Ortho anti-HCV ELISA test for use in the USA. Ortho announced on 4 May that the kits were being shipped to US blood centres and that screening of the US blood supply would commence immediately.<sup>306</sup> The announcement added that Ortho was supplying anti-HCV test kits to Europe, Japan, Canada and Australia.

**31.210** Professor Cash told the Inquiry in his statement, that FDA licensing was regarded as important. The scientific process of assessment of diagnostic kits by the FDA was rigorous. No kit licensing arrangements existed in the UK.<sup>307</sup>

**31.211** In his oral testimony Professor Leikola said that FDA licensing was not an important factor for the Finnish Red Cross. They had decided to proceed with the test based on their own observations and opinions on the Ortho kit. The earlier grant of an export licence to Ortho was enough for them to proceed, and they were not deterred by the possibility the FDA might refuse to license the test for use in the USA. Professor Leikola added that the FDA dealt with different issues when considering the blood transfusion system in the USA and their relationship with the blood banks and different laboratories. It was more complex in the USA. In Finland they had just one laboratory which had decided the test kit worked satisfactorily, and they did not expect the FDA to refuse to license its use 'in-country'.<sup>308</sup>

**31.212** If the FDA had refused to license the test in the USA, the Finnish Red Cross would have had to consider the reasons for that and decide if it was relevant to them and to consider any impact on their own screening system that might result. If there was something incorrect in the manufacturing of the test kit or inconsistencies between batches of the tests it would have impacted on the quality of the test kit and caused concern in Finland.<sup>309</sup>

**31.213** In a letter dated 11 May 1990, Ortho in the UK wrote to Professor Cash to confirm the arrival of its RIBA test: 'This exciting new assay is designed to detect the presence of antibodies to hepatitis C virus in samples that have given a positive result with the Ortho\* HCV antibody ELISA test'.<sup>310</sup> The letter from Ortho did not comment on whether the RIBA was developed as a 'confirmatory' or a 'supplementary' test, simply that it could detect the presence of antibody to HCV in samples which already tested positive with the ELISA. In later practice, the PCR test became the preferred confirmatory test as it detected the virus itself and was based on a different principle. Professor Cash considered the first RIBA to be a supplementary test, rather than a confirmatory test. But it did assist in convincing scientists that they had found a true positive.<sup>311</sup>

### July 1990 meeting of ACVSB brought forward

**31.214** Dr Metters wrote to members of the ACVSB on 5 June 1990.<sup>312</sup> He advised that the extended prospective study discussed at the last meeting to investigate the significance of positive findings from the anti-HCV ELISA test, was no longer considered appropriate

<sup>306</sup> Ortho announcement [SGF.001.2036]

<sup>309</sup> Ibid, page 120

<sup>310</sup> Letter [SNB.004.5013]

<sup>311</sup> Day 71, page 112

<sup>312</sup> Letter re: ACVSB Meeting [SNB.002.0245]

'in light of subsequent developments'. These developments were said to be (unspecified) additional scientific information that had become available and the fact that the FDA had approved the Ortho test for routine use in the USA. He indicated a fairly urgent wish to bring the next ACVSB meeting (which had been fixed for 24 July) forward to 2 July and devote it entirely to Hepatitis C testing and felt the committee now needed to consider whether UK blood donations should be routinely screened for Hepatitis C.

**31.215** He set out the questions to be addressed:

1. What new information is available about the screening tests themselves, or on the use of supplementary (RIBA) and confirmatory (PCR) testing methods?
2. Has the FDA decision to approve the test and decisions of other countries to implement testing been influenced by some scientific or other information which has now become available?
3. Are there any advantages attached to either of the two tests currently available (Abbott and Ortho) in respect of specificity, sensitivity, operational ease of use, cost?
4. If routine testing were to be introduced what implications would this have for the UK BTS? How would positive findings (*sic* – probably 'findings') be dealt with? What supplementary or confirmatory testing would be required and where would this be carried out? How and when would the donor be counselled?
5. If testing is to be introduced in the UK should it be limited to whole blood or also extended to plasma donations bearing in mind the supposed efficacy of heat treatment? Are all current methods of viral inactivation successful in respect of hepatitis C?<sup>313</sup>

**31.216** On 6 June 1990 Dr McIntyre wrote a memorandum to Dr Young (DCMO, SHHD) commenting on Dr Metters' letter and the fast moving developments that were taking place.<sup>314</sup> Dr McIntyre had little doubt that the committee would recommend the introduction of the screening test. He remarked that the large prospective study planned at the last meeting was to be abandoned as it was no longer appropriate and advised that matters should be put on hold pending the ACVSB meeting on 2 July. Mr Panton of SHHD added a manuscript note to the memorandum, addressed to his colleague Mr Hogg, to tell him they should still press for funds despite the study being abandoned.

### Further new study

**31.217** The ACVSB met on 2 July 1990 for 'reconsideration' of the decision made at the committee's April meeting.<sup>315</sup> Dr Rejman outlined the sequence of significant events: the FDA had approved Hepatitis C screening, the USA had introduced it and other countries were following. He said that more studies had been carried out confirming that Hepatitis C testing reduced infection, and that RIBA was available as a supplementary test. The minute does not identify the additional studies although the agenda noted that a summary

<sup>313</sup> Note of a Meeting of the ACVSB on 02 July 1990 [SNB.002.0247]

<sup>314</sup> Memo [SGF.001.2034]

<sup>315</sup> Meeting Minutes [SNF.001.1705]

of the basis for approval by the FDA had been tabled. The proposed extended prospective study agreed at the previous meeting was 'no longer viable'. Professor Zuckerman felt it was time for screening to go ahead on public health grounds, although he thought counselling would pose some difficulty.

**31.218** After discussion, the committee concluded that it should recommend to Ministers that anti-HCV screening should be introduced, but that a pilot study was necessary first, to look at both the Abbott and the Ortho kits using the protocol drafted for the initial aborted study, to decide which was the better test kit.<sup>316</sup> The first two questions posed by Dr Metters appear to have been disposed of without separate discussion. Further study would resolve question 3. Question 5 was dealt with on what appears to have been a sensible basis: antiviral treatment was not guaranteed to be effective, and consistency required that all donations be treated alike. The matter of counselling, as focused in question 4, was discussed: national consistency on this was required and the working group would continue to look at the whole topic of counselling.

**31.219** Dr Gunson advised that Wellcome (a British company) was also developing a test which would be ready in September/October. The pilot study would go ahead without delay and frozen library samples would be kept so that donations could be retested later against other tests, such as Wellcome's, as they became available.

**31.220** A draft proposal for a three centre comparative trial of the first generation Abbott and Ortho tests was circulated at the ACVSB meeting.<sup>317</sup> The document noted that evidence from Finland indicated that supplementary testing at specialist laboratories should eliminate approximately two-thirds of the reactive samples. The comparison was to be done at North London, Newcastle and Glasgow RTCs, which would each carry out around 3500 tests. Confirmatory tests were to be carried out using Ortho RIBA, Abbott confirmatory test, and immunoassays based on other HCV proteins (if available). This study would take around four months to complete once finance was agreed. Contrary to the impression that might be created from the meeting having been advanced by three weeks, as Professor Leikola commented in his second statement, 'there was still no rush'.<sup>318</sup>

**31.221** According to Dr Mitchell, the comparative study was necessary because not all laboratories were using the same technology. Some were already familiar with Ortho technology and some with Abbott. It was important for the three laboratories involved to compare results from the two test systems and try to ensure they had detected the same thing.<sup>319</sup>

**31.222** Dr Perry thought the studies had different objectives.<sup>320</sup> In his statement, he resisted the suggestion that the time taken for the second 'replacement' pilot study was wasted. It would be best practice for a new test system, in this case Abbott's, to be validated. It would be useful to identify any problems, or advantages, with wide-scale use of either of the kits.<sup>321</sup> The second study would be looking at the relative performances of the two kits with a view to deciding if there were benefits from one over the other. The UK

<sup>316</sup> Ibid [SNF.001.1705] at 1707

<sup>317</sup> Draft proposal [SNB.006.1846]

<sup>319</sup> Dr Mitchell's Statement [PEN.017.1901] at 1911

<sup>320</sup> Day 68, page 117

<sup>321</sup> Dr Perry's Statement [PEN.017.2108] at 2116

population could well have different characteristics from that in the US, and still relatively little was known of the Hepatitis C virus, so it made sense to look at both kits. If one kit had been better than another in one country, it did not mean it would be the best choice elsewhere.<sup>322</sup> While noting these possibilities, Dr Perry did not suggest any difference in format or indicate any underlying scientific reason that might have led to an expectation that there would be major differences between the two tests.

**31.223** It is observed in passing by the Inquiry that, in proposing this study, the ACVSB appears clearly to have been entering into the 'operational implications of policy' – the function of the ACTTD – and widening the area of responsibility accepted by the committee as articulated by Dr Metters on 24 April 1990. Having decided at their meeting on 2 July 1990 to recommend, as a matter of policy, that HCV screening of blood donors should be introduced, it is not clear why the ACVSB considered that it should become involved in deciding which test kit should be used by RTCs. On the face of it, that was an operational matter for the blood transfusion services, which fell within the remit of the ACTTD.

**31.224** In any event, the ACVSB underestimated the time it would take to assess the results of the pilot studies and decide its next step. The final report of the tri-centre study, incorporating Phases I and II, was not available until February 1991. Professor Leikola observed in his second statement that 'the outcome of the 2 July meeting meant at least half a year's delay in the introduction of the screening. As it turned out, the time span was more than two times longer'.<sup>323</sup>

**31.225** Professor Leikola was asked in oral evidence whether, in his view, screening had to be delayed until the Ortho and Abbott comparison was completed. He accepted that the comparison was necessary, but he did not feel it justified a delay in the introduction of testing.<sup>324</sup> He pointed out in his second statement that the comparison could have been undertaken while screening was up and running using the Ortho kit.<sup>325</sup> It could have been introduced in May 1991, after the FDA decision to license the Ortho test, and screening could have been given the 'go ahead' in July. Professor Leikola would not have expected there to be a major difference between the Ortho and Abbott kits: both were based on the same protein and the same patent from Chiron.<sup>326</sup> He noted that the philosophy in Finland was that 'if a new test seems to be inevitable, it pays off to start it as soon as possible, and then with flags waving'.<sup>327</sup>

**31.226** Professor Leikola commented in his initial Inquiry statement that a decision to introduce anti-HCV screening could have been made in June or July 1990:

[T]here was no clear mechanism for making a definitive decision concerning the whole UK. The time needed for practical arrangements in the blood centres could have been a maximum of four to five months, so the screening could have been in place in late 1990, possibly in October-November 1990.<sup>328</sup>

**31.227** This inevitably assumed a steady progression to implementation in a variety of blood transfusion centres once a decision had been made. Professor Leikola accepted in

<sup>322</sup> Day 68, page 119

<sup>323</sup> Professor Leikola's Statement [PEN.017.1961] at 1963

<sup>328</sup> Ibid [PEN.017.1957] at 1959-60

oral evidence that it would have been much more achievable in Finland with one centre than in the UK where there was a variety of transfusion centres and organisations.<sup>329</sup>

**31.228** In his first Inquiry statement on this topic, Professor Leikola was asked to comment on the reasons for the delay in the decision to implement anti-HCV screening in the UK. He thought they were threefold:

- There was a lack of a proper prospective study on the incidence of transfusion transmitted hepatitis. There had been studies, but they were too small.
- There was pressure from the academic scientists in the ACVSB and ACTTD who preferred a cautious view of the usefulness of the test kits for routine use.
- There was also reluctance on the part of some blood centres to introduce screening, which would have involved them discarding an appreciable amount of blood donations and having to counsel an increased number of donors.<sup>330</sup>

In fact, on 9 October 1989, the ACTTD had recommended to the ACVSB that screening should be introduced (subject to conditions).

**31.229** In September and October 1990 Ortho intimated that a second generation anti-HCV ELISA test and a second generation RIBA confirmatory test would soon become available for clinical trials.<sup>331</sup> While the first generation ELISA detected antibodies to HCV non-structural (c100-3) antigen, the second generation ELISA detected antibodies to a combined, larger, non-structural (c200) antigen and a structural (c22-3) antigen. The second generation RIBA test was a four-antigen test, in which two additional antigens (c33c and c22) had been added to the first generation RIBA test (containing the c100-3 and 5-1-1 antigens). Two short papers presented at a Hepatitis C symposium in Los Angeles in November 1990 (attended by Dr Gillon, SNBTS, Edinburgh), concluded that the second generation ELISA offered improved sensitivity and specificity in a variety of clinical populations.<sup>332</sup>

**31.230** In the review paper published in 1993, mentioned in paragraph 31.133, Professor Leikola described the progress made with the introduction of second generation RIBA testing:

The sensitivity and specificity of the test have been improved by adding two more antigens to the assay, the non-structural protein C33c, and the structural core protein C22.<sup>333</sup>

**31.231** There were still reservations, however:

[T]he sensitivity of the confirmatory tests is not yet optimal, and it can be estimated that the true prevalence of anti-HCV antibodies in Northern European populations is approximately 0.05-0.1%, and it increases up to 1% or more in geographical areas where hepatitis viruses are more common.<sup>334</sup>

## November 1990 meeting of ACVSB

**31.232** By the time of the eighth meeting of the ACVSB on 21 November 1990,<sup>335</sup> a note had gone to Ministers intimating that the committee was in favour of introducing HCV screening. There was no indication whether or not Ministers had responded. It was anticipated that there would be a further submission following a decision at the meeting, as to which test would be most suitable.

**31.233** At the November meeting Dr Gunson reported on Phase I of the tri-centre pilot study.<sup>336</sup> Professor Cash said in oral evidence that one concern with using different kits was that a donor tested in Glasgow might be told they were positive for anti-HCV, but if tested in Edinburgh they could be negative. This was because different tests used different criteria and a borderline case could have different outcomes in different centres.<sup>337</sup> In the event, Dr Gunson reported that there was little to choose between the two tests: transfusion centres could decide individually whether to use the Abbott or Ortho kit, which might depend on the equipment already in their possession.<sup>338</sup> That was the only recommendation to come out of this study.<sup>339</sup> The minutes record confirmation by several members that better (ie second generation) tests were being developed and would shortly be issued. The inconsistencies in test results were noted by Professor Zuckerman at the meeting.<sup>340</sup>

**31.234** It will be necessary to return later in this chapter to the detail of some of that discussion. At this stage, it is noted that the committee agreed that the UK should introduce screening as soon as practicable, with individual RTCs deciding whether to use the Ortho or the Abbott test.<sup>341</sup> The minutes record that, 'A submission would go to Ministers regarding this significant policy decision and the Management Executive would consider the funding aspect'. Further action would depend on Ministers' policy decisions. Thus, there was no reference to any agreed method of informing the transfusion centres of the plan. No suggested date for introduction featured in the minutes of the meeting, although Dr Gunson reported some RTCs had asked for six months to set up testing.<sup>342</sup> According to Dr McIntyre's note of the meeting, the Chairman suggested 1 April 1991 as a start date.<sup>343</sup>

**31.235** The committee discussed some of the practical aspects of the introduction of testing, such as counselling. Dr Gunson said that the ACTTD would meet to discuss the problems of counselling donors and to develop a strategy.<sup>344</sup> Both Dr Gunson and Dr Mitchell felt that if the results of the pilot study giving six true positives out of 10,000 donors were borne out in practice, then counselling would be manageable.

**31.236** With regard to this meeting Dr Perry said in his statement to the Inquiry that it 'was widely understood that DoH and UK Ministers had ... established the principle of a common start date for testing and this position was periodically reiterated at ACVSB'.<sup>345</sup>

<sup>345</sup> Dr Perry's Statement [PEN.017.2108] at 2117

***Communication of ACVSB decisions to Scotland***

**31.237** Dr McIntyre produced a note of the ACVSB meeting held on 21 November 1990 for his colleagues in the SHHD.<sup>346</sup> He reported that ‘some’ members wanted to start screening forthwith, but that the Chairman suggested 1 April 1991 was more realistic. Dr Perry attended this meeting and it was not clear to him, giving evidence to the Inquiry, who were the ‘some’ in favour of the forthwith introduction of testing.<sup>347</sup> There is no record in the committee minutes themselves of a suggested start date. The date may have been suggested in a discussion that took place ‘off agenda’. It may not have been adopted as the consensus decision of the meeting or, for some reason, may simply not have been minuted.<sup>348</sup>

**31.238** According to Dr McIntyre’s report, it was agreed that a submission would be drafted for the Ministers and copied to Scotland, Wales and Northern Ireland.<sup>349</sup> It was also recorded in the minutes that a submission would be sent to Ministers.<sup>350</sup> Mr Tucker explained that it was common for the DoH to send draft submissions to the individual health departments to demonstrate what they were putting forward to Ministers.<sup>351</sup>

**31.239** Dr Mitchell wrote a letter dated 23 November 1990 to Professor Cash following this meeting of the ACVSB.<sup>352</sup> He did not give a date for the commencement of screening but reported that it had been decided:

To introduce testing for anti HCV using either the Ortho or the Abbott test depending on local circumstances and experience of individual RTCs. The exact date of introduction would be at the earliest practical moment but it was reiterated that the UK would proceed in unity.

**31.240** Dr Gunson was to consult with English colleagues and distribute copies of his Phase I report to assess the likely update of the technical resources required and the likely start dates. There would be a report to the ACTTD meeting in Manchester in January.

**31.241** It appears to be clear that steps were in hand to explore the practical implications of implementation in England and Wales. Northern Ireland was not mentioned in Dr Mitchell’s letter, and it did not refer to any similar arrangement for Scotland. Professor Cash was not a member of ACVSB, as Dr Gunson was, and appears to have been left to consider the Scottish situation unguided by the ACVSB directly, with the benefit only of informal information from Dr Mitchell.

**Professor Cash advances matters in Scotland, November 1990**

**31.242** It appears that there were informal contacts between Professor Cash and Dr Mitchell, since Professor Cash was able to inform SNBTS colleagues that he and Dr Mitchell had a common view of the way forward. In response to Dr Mitchell’s report of the ACVSB meeting, Professor Cash wrote to the SNBTS directors on 27 November 1990:

<sup>346</sup> Note of Meeting [SGH.002.8501]

<sup>347</sup> Day 68, page 123

<sup>348</sup> As with discrepancies between the minutes of meeting on 24 April 1990 and other notes – see paragraphs 31.176 and 31.205 above

<sup>349</sup> Note of meeting [SGH.002.8501] at 8502

<sup>350</sup> Meeting Minutes [SNF.001.1777] at 1780

<sup>351</sup> Day 69, page 116

<sup>352</sup> Letter [SNB.005.3696]

I am advised by Ruthven [Mitchell] that we are a wee bit nearer to “D-Day” and we both believe that it would be to our corporate advantage to take a further step forward along the planning route.

It now seems clear that, in the context of quality, both the Ortho and Abbott kits ... are acceptable: the choice will be yours. We now need to know (as part of an information gathering exercise designed to obtain a UK consensus for a future simultaneous start date) when would be the earliest date you could start routine screening and have your counselling team in place.<sup>353</sup>

**31.243** Professor Cash was asked in oral evidence what he meant by ‘corporate advantage’. He thought it was no more than a reflection of his anxiety that the SNBTS ‘as a team, stayed as a team’.<sup>354</sup>

**31.244** Professor Cash’s view, stated in oral evidence, of what was meant by a ‘start date’ was the point at which transfusion centres would be in a position to test all blood products on their shelves in order for them to be pronounced safe on the same date. For centres to reach that stage, however, he stated that he would have been willing to accept that different centres would have to unwrap their kits and start testing their products at slightly different times.<sup>355</sup> A ‘slightly’ different start date would have been acceptable to him, as different centres had different logistical issues, but it would not have been acceptable for an individual centre to commence testing months in advance of the suggested date.<sup>356</sup> His ideal was for the individual transfusion centres to aim for the same completion date, when they could say all of the units of blood on their shelves were safe.<sup>357</sup>

**31.245** There was to be further debate about the meaning of the term ‘start date’. By the time Professor Cash wrote to Mr McIntosh four months later with the results of the agreements reached at the ACTTD meeting of 25 March 1991, the definition had been refined:

The definition of a start date now proposed will be exactly as stated – the date when routine HCV donation testing will commence. NBTS colleagues do not wish to accept the original proposal (which applied to HIV-1 testing) that the definition of a start date would be that on that date all RTC products issued would have been HCV tested.<sup>358</sup>

**31.246** The North of Scotland Transfusion Centre in Inverness replied on 6 December 1990 to Professor Cash’s letter of 27 November. The technical aspects of testing could be set up at short notice, but a system of donor counselling would be complicated and take around two months to establish.<sup>359</sup>

**31.247** The South East Scotland region replied to Professor Cash on 19 December in a letter composed by Dr Gillon.<sup>360</sup> The earliest date routine screening could start was 25 February 1991. They proposed to use the Abbott test system. Dr McClelland commented in oral evidence that the transfusion centre might have been ready in ‘purely transfusion’ terms,

<sup>355</sup> *Ibid*, pages 151-52

<sup>356</sup> As noted below, the context for this comment was that the Newcastle Centre broke ranks and implemented screening early: see paragraph 31.349 below.

<sup>357</sup> Day 72, page 153

<sup>358</sup> Letter [SGF.001.2026]

<sup>359</sup> Letter [SNB.004.7189]

<sup>360</sup> Letter [SNB.004.7202]

but in reality there would have been no ministerial approval or the necessary finance in place to proceed with screening.<sup>361</sup>

**31.248** Edinburgh and South East Scotland began preparations for routine testing in mid July, using stored samples to evaluate equipment. The SNBTS informed the Inquiry that its laboratory manager's records showed that the Edinburgh and South East Scotland BTS began testing all of their blood products for anti-HCV on 30 July 1991. That was done so that all products on the shelf on 1 September 1991 could be said to have been tested.<sup>362</sup>

**31.249** The Inquiry has been unable to locate any letters from other regional directors responding to Professor Cash's letter of 27 November 1990.

**31.250** On 21 December 1990, Mr Canavan (DoH) produced a note seeking Ministers' approval to commence screening in the NBTS, as a public health measure in line with the unanimous advice of the ACVSB that screening should be introduced as soon as practicable.<sup>363</sup> The note stated that, in view of the operational matters that needed to be discussed and finalised, it was unlikely that routine screening could be introduced before 1 April 1991.<sup>364</sup>

### Decision-making process in Scotland

**31.251** The development, and the effectiveness, of the management structures of the SNBTS is discussed in Chapter 17, *Blood and Blood Products Management*. From 1978 there had been a blood transfusion sub-committee of the CSA Management Committee, with a wide remit and delegated powers to deal with blood transfusion matters.<sup>365</sup> Notwithstanding the formal structural changes introduced in 1978, the Blood Transfusion Service would continue to be characterised by a high degree of local autonomy.<sup>366</sup> In 1990 the management structure of the SNBTS underwent a process of change. There had been concern that there had been a lack of professional management of the SNBTS under the existing system. The post of SNBTS General Manager was created. SNBTS Directors were made accountable to the General Manager on managerial aspects and professionally accountable to the National Medical and Scientific Director. There was one central body, the Management Board, through which all policy and strategic decisions passed.<sup>367</sup>

**31.252** Mr David McIntosh was appointed as the first General Manager of the SNBTS in February 1990, and subsequently became Chairman of the Board of Directors in May of the same year.<sup>368</sup> The Management Board met for the first time on 19 June 1990 to finalise its remit in the new structure.<sup>369</sup> Mr McIntosh gave oral evidence to the Inquiry on 29 November 2011. Professor Cash, as National Medical Director, had tended to liaise with medical colleagues within the SHHD directly, by-passing the CSA. Mr McIntosh said that, formally, Professor Cash became the Deputy Chairman of the Board at the same time as he was appointed. In formal terms, the Medical Director was now responsible to the General Manager and not vice versa.<sup>370</sup>

<sup>370</sup> Day 70, page 7

**31.253** In his own view, Mr McIntosh had a clear understanding of what the relationships among parties should have been. As he saw matters, the individual health departments were responsible for presenting recommendations for decisions to their own Minister or Ministers.<sup>371</sup> The Scottish Health Service of the day was responsible to Parliament through the Secretary of State for Scotland and there were Ministers who would be responsible to him for health matters. Mr McIntosh was confident that Scottish decisions would take into account views from England, but that decisions would ultimately be made separately in Scotland. Scottish 'compliance' with English decisions could not be assumed. He made the point that the SNBTS would not have acted on any significant policy initiative without the authority to do so from the Secretary of State for Scotland, filtered through to them by the Health Minister or civil servants at the SHHD.<sup>372</sup>

**31.254** Whether his analysis was technically correct or not, there was a perception within the SNBTS of the relationships of the several participants, and disturbing such equilibrium as had been established in practice would not be easy. There were tensions as Mr McIntosh approached his task, as he saw it, of seeking to improve the previous administrative arrangements for the governance of the SNBTS.

**31.255** Mr McIntosh suggested in his statement that there were three periods of time in the lead-up to the introduction of testing: an initial period of 'genuine debate' about the necessity of HCV testing, a second period of 'genuine professional deliberation' and, from the end of March 1991 to the end of August of that year, a period of 'successive delays'.<sup>373</sup>

**31.256** It appeared to him that the view in Scotland in very early 1991 was that coordination with English implementation of testing was desirable and to be followed if at all possible.<sup>374</sup> The bodies in England that were advising and guiding decision making in Scotland had no responsibility for patient care in Scotland.<sup>375</sup> In formal terms, he was correct: the SNBTS was not directly dependent on Westminster funding. The allocation of expenditure from the Scottish block grant (determined by the Barnett formula from 1978) was purely a Scottish matter. But there was a single UK Government and, realistically, if there was a UK policy decision that screening should be introduced across the UK on a single date, reluctance to incur cost in England and Wales would have an indirect effect on what could be done in practice in Scotland.

### Slippage at the start of 1991

**31.257** Following on the DoH submission of 21 December 1990 seeking Ministers' approval to commence HCV screening of blood donors by the NBTS,<sup>376</sup> Mrs Sandra Falconer (SHHD) produced the following note on 4 January 1991:

[Mr Kennedy, DOH, Belfast] wanted to speak to Rab [Panton] about Hep C submission. He asked if we had put forward to Minister yet and if we had funding. Explained we were still working on submission and that bid for funding had been made but you were awaiting Mr Panton's return on Monday to discuss PES allocation & finalise submission.<sup>377</sup>

<sup>376</sup> Note [SGH.002.7893]

<sup>377</sup> Handwritten note [SGH.002.7891]

**31.258** There was a meeting of the NBTS/SNBTS Liaison Committee on 7 January 1991.<sup>378</sup> Dr Gunson attended and expressed his concern that the DoH had not yet decided on a start date. It was suggested that it was probable that a date in May or June 1991 would be the earliest possible. Dr Gunson added that he thought the major problems were mechanisms for finding the money for the RTCs in England and Wales and for confirmation testing. Professor Cash's notes of the meeting state, 'The issue was one of DoH's disinclination to fund centrally and insist on cross charging i.e. increasing the unit cost of blood supplied to hospitals'. Professor Cash requested a more definitive description of 'start date'. Dr Gunson advised him that would be discussed at the next 'Microbiology Advisory Group Meeting' on 8 January.<sup>379</sup>

**31.259** After an interval of 10 months, the ACTTD met again on 8 January.<sup>380</sup> The minutes of the meeting noted that, 'It will be important for RTCs to start testing on an agreed date'. As with the ACVSB meeting of 21 November, the discussion on anti-HCV screening was dominated by setting out the details of the procedure to follow for positive test results. Dr Gillon attended and his paper on counselling of donors was also discussed. He agreed he would amend it in response to written comments from other committee members.

**31.260** On 16 January 1991 a short government memorandum was issued on behalf of Baroness Hooper, Parliamentary Under Secretary of State for Health, in response to Mr Canavan's note of 21 December 1990.<sup>381</sup> Screening for anti-HCV should be introduced as soon as practicable. No suggested date or timetable was given and no guidance was offered to suggest the commencement date. Baroness Hooper said there was no option but to introduce anti-HCV testing.

**31.261** On 21 January Mr Tucker sent a memorandum to Mr Panton passing on the information from Mr Canavan, that DoH Ministers had given their approval to the submission on HCV testing.<sup>382</sup> Mr Canavan did not know the start date, since some laboratories would require new equipment. There was to be a meeting of RTDs to explore the practical issues. Mr Tucker had suggested to Mr Canavan:

[T]hat it might be better to set a target of 1 April as the earliest possible date for introduction but leave it to Blood Transfusion Centres to come in line thereafter since to delay for the slowest could mean a long wait.

**31.262** He asked Mr Panton to proceed with a draft Scottish submission to Mr Forsyth, and to ascertain the earliest date the SNBTS could commence testing, whilst maintaining a 'UK approach'. It is not clear from the face of the memorandum if it was sent on that date. There is a further manuscript note by 'SF' – who is assumed to be Mrs Sandra Falconer – and that suggests it was not copied to Mr Panton until 14 February. Even then he was asked to work on the second, unrelated issue of 'handling charges for blood', described in the memorandum.

<sup>378</sup> Notes of NBTS-SNBTS Management Meeting, 7 January 1991 [SNB.011.7258]. In attendance were Dr Gunson, Professor Cash and Dr R J Moore

<sup>379</sup> As at 7 January 1991, it was expected that the next meeting of the ACVSB would be in late January 1991 (see [SNF.001.1777]). In the event it was held on 25 February 1991. It is unclear what meeting Dr Gunson had in mind. The only meeting that was held on 8 January 1991 was a meeting of the ACTTD.

<sup>380</sup> Meeting Minutes [SNB.001.8770]

<sup>381</sup> Memo [PEN.016.0259]

<sup>382</sup> Memo [SGH.002.7890]

**31.263** Mr Tucker commented in oral evidence that he would have preferred to set a target date for the introduction of screening; he would not have been comfortable with going to his Minister without a start date.<sup>383</sup> He suggested 1 April in his memorandum as the Public Expenditure Survey (PES) had been approved by Ministers in Scotland and funding was available for that date, adding in oral evidence: 'Then we could all move forward at the same time'.<sup>384</sup> Mr Tucker thought there would be no point in the DoH, or the SHHD, setting a date for screening if the transfusion centres themselves were not ready. There would have to be close consultation among the parties involved in decision making and implementation.<sup>385</sup>

**31.264** On 22 January 1991, Dr Gunson sent a memorandum to the Regional Transfusion Directors of England and Wales.<sup>386</sup> He advised them that routine testing would be put into action and asked for the earliest date they could commence screening. This appears to be Dr Gunson's equivalent to Professor Cash's letter to his Directors of 27 November 1990.

**31.265** Dr Gunson's memorandum was copied to Professor Cash, who replied on 24 January.<sup>387</sup> External factors – the kind of events that change history – had a bearing on what was practicable. On 14 September 1990, British forces were deployed to Saudi Arabia following Iraq's invasion of Kuwait. On 16 January 1991, the United States of America announced operation 'Desert Storm'. War had again impacted on the work of the SNBTS. Professor Cash advised Dr Gunson that anti-HCV testing could not commence until either the Gulf conflict had ended or the SNBTS teams had proved themselves able to cope with the pressures of both the conflict and HCV testing. The demands created in anticipation of the actual conflict were exhausting staff and Professor Cash judged that, when the troops went operational, the 'current frenetic activity' of the SNBTS would be sustained. Professor Cash added in his oral testimony that '90 per cent of the blood that was made available for British troops involved in the conflict in the Gulf came from Scotland'.<sup>388</sup> In his letter of 24 January to Dr Gunson, Professor Cash went on to say:

We remain firmly committed to starting on the same day as our NBTS colleagues and if pressed by Ministers I would suggest, in the circumstances, a May/June date should be considered. However, I would much prefer to wait another month and then respond to your letter.

**31.266** Dr McClelland agreed in evidence that the UK services, at that time, were preparing themselves for a potentially large number of casualties of the war in Iraq being flown to hospitals in the UK. In addition, the transfusion services were inundated with extra blood donations.<sup>389</sup> In the event, the military offensive comprised an initial prolonged aerial bombardment and a ground assault which commenced on 24 February and which ended when Iraqi forces agreed a ceasefire four days later, on 28 February. However, by that stage, the preparatory arrangements in anticipation of conflict had impacted heavily on the SNBTS.

<sup>386</sup> Memo [SGF.001.2029]

<sup>387</sup> Professor Cash's reply [SGH.002.7887]

<sup>388</sup> Day 72, page 162

<sup>389</sup> Day 69, page 40

**31.267** On this occasion Professor Cash was supported within the SHHD.<sup>390</sup> Dr Gunson responded on 28 January, without reference to the demands created by conflict, and advised Professor Cash:

It was never my intention that anti-HCV testing should take place with great urgency. The reason I asked if it was possible to let me know by Tuesday feasible dates for the commencement of testing was because I have a meeting at the DOH on Wednesday to discuss this matter. It was not intended to pressurise RTCs to start testing in the immediate future which, I agree, is entirely impractical. For England and Wales, as you know, there is a matter of financial provisions for this testing to be sorted out.<sup>391</sup>

**31.268** The interpretation of this superficially rather puzzling letter is unclear. It may have been intended as support for Professor Cash, noting that England and Wales also had problems that might delay implementation. On the other hand, one cannot avoid the impression that Dr Gunson's views of the practicalities in England and Wales would always have precluded any commitment to urgent implementation of the decision to commence anti-HCV testing in the UK, including Scotland for the reasons noted above.

**31.269** In the meantime, the evaluation of test kits continued. On 24 January 1991 Dr Follett advised Dr Gunson of initial results from the Glasgow study, which indicated that the second generation Abbott anti-HCV test 'looks most promising .... Clearly the inclusion of the new C22 and C33 antigens has transformed this test'.<sup>392</sup> These antigens were introduced into the Abbott RIBA test, as indicated above.

### **Abbott's intellectual property problems**

**31.270** The intention to have an evaluation of 1000 Abbott ELISA kits was, however, frustrated. On 4 February 1991, Dr Follett wrote to Dr Gunson to say Abbott had supplied only four test kits. Abbott was prevented from providing further kits until 14 April as Ortho had taken out an injunction preventing their sale in the UK until after that date.<sup>393</sup> As indicated above, Abbott's licence had included restrictive provisions protecting Ortho's access to the market for one year.

### **Postponement from 1 April 1991**

**31.271** Dr Pickles of the DoH composed a memorandum on 5 February 1991, copied to certain members of the ACVSB but not to anyone in Scotland.<sup>394</sup> She commented that there were many problems with the proposed introduction of testing, such as choice of test, supplies, confirmatory testing and training of staff. Funding was still a very real concern. Following discussion with the RTCs, Dr Gunson had suggested to Dr Pickles that the start date should be 1 July, and she wondered if that would be too late. Dr Pickles set out her view:

My initial reaction was this would be OK. Attempting to go earlier would mean some stragglers would be left behind, the slight delay increased the chance of the finance being sorted out, and with the diversion of RTC resources to Gulf-

<sup>394</sup> Memo [PEN.016.0236]

related activities a short time date might not be feasible. Even that date was dependent on blood collection having been stable for the preceding 4 weeks, which should apply provided the ground war is over by then.

Do you agree? We will discuss in more detail at ACVSB, I presume.<sup>395</sup>

**31.272** 1 July had now emerged as the date of implementation of screening in place of 1 April. It is of importance to note the position on funding in England and Wales. As noted already, Dr Metters had stated at the ACVSB on 17 January 1990 that no new money would be made available for screening: funding would have to be found from existing allocations. Dr Pickles' memorandum indicates that, over a year later, the problem of funding in England and Wales had still not been resolved.

### **Funding in Scotland**

**31.273** Formally, the funding structure in Scotland was clear. In summary, SHHD funding came from the Scottish Office budget which was ultimately tied to the Treasury. The SHHD had its own Finance section which was overseen by the Scottish Office Finance Department. The SHHD had responsibility for the overall management and financing of the Common Services Agency, which in turn funded the SNBTS.<sup>396</sup>

**31.274** Mr McIntosh agreed with this summary put forward by Mr Tucker. However, as he recalled, the CSA took no part whatsoever in the chain of command as he saw it. Effectively, the SNBTS reported to Ministers through the Home and Health Department. He could not recall any CSA interest in the process of the introduction of anti-HCV testing.<sup>397</sup> This was consistent with the position that obtained generally, and as described in Chapter 17, *Blood and Blood Products Management*. The CSA was a conduit for budgeting and the allocation of funds, but it had no operational role in the formulation or implementation of policies directing or affecting the work of the SNBTS. Budgeting was provided through the mechanism of the annual PES; procurement was a separate issue.

**31.275** Mr Tucker told the Inquiry in his statement that there was a national procurement process. The Health Departments would seek to negotiate contracts on a national basis with the aim of obtaining the best value for money. The SHHD would not negotiate alone for products, as it would not have the purchasing power of the national procurement programme.<sup>398</sup> He added in his statement that SNBTS staff would not try to purchase outside of the nationally agreed contracts as it would have been far more expensive.<sup>399</sup>

**31.276** Mr Tucker commented that it was common for the DoH to take the lead in national issues. The SHHD was a smaller Health Department, with fewer resources; there was a general desire to make use of DoH resources. It made sense for the SHHD to be in partnership with the DoH and both obtained the same advice from the ACVSB. The DoH as the bigger organisation was better able to exert pressure on the Treasury.<sup>400</sup>

### *Public Expenditure Survey*

**31.277** On the agenda for the SNBTS management board meeting of 12 February 1991, it was noted in relation to the Public Expenditure Survey 1990 (PES90) that of a total sum of £2.5 million available for new developments, £1.1 million would be needed for anti-HCV testing.<sup>401</sup>

**31.278** On 12 February 1991 the Management Board of the SNBTS met 'to review the firmed up PES proposals for 1991/92'.<sup>402</sup> The agenda included testing for anti-HCV as 'Microbiological Screening – Anti-HCV'.<sup>403</sup>

**31.279** In the original bid (submitted to the CSA and the SHHD in June 1990),<sup>404</sup> total capital and revenue expenditure of £1.332 million had been sought (capital of £50,000 and revenue of £1.282 million) to introduce anti-HCV testing in 1991/92. In the revised bid, £1.223 million (£106,000 of capital and £1.117 million of revenue) was sought for that purpose. A detailed breakdown was provided.<sup>405</sup>

**31.280** It appears that the meeting in February 1991 may not have completed discussion of the detail of the bid for anti-HCV screening. It was planned to continue the discussion at a further board meeting in April 1991. It is however clear that the bid for the funding of screening for HCV was included in PES90, that it was successful and that (in contrast to the apparent state of affairs in England and Wales) the funding was available to commence routine screening in Scotland in April 1991.

**31.281** Mr Tucker commented in oral evidence that this implied that testing could begin in April 1991: the Minister had agreed testing as he had approved an allocation of funds in the PES for 1991/1992.<sup>406</sup> He said that there was no allocation of funds for HCV screening in the PES for 1990/1991.<sup>407</sup> That would have been drawn up in June or July 1989, and the need for funding would not have been known at that stage. The only money available for HCV screening in the financial year 1990/1991 would have been from the contingency fund, or spare money in the CSA budget. That led to a discussion of the use of the contingency fund.

### *Reserve/Contingency fund*

**31.282** The Inquiry asked the witnesses who provided statements whether, if screening had been introduced before the financial year 1991–92 (and specifically in year 1990–91), the money required could only have been found in the 'central reserve' (the contingency fund referred to in an SHHD memo of 2 July 1990).<sup>408</sup>

**31.283** All witnesses were referred to paragraph 2996 of the Minutes of the Meeting of the Management Committee of the CSA for the Scottish Health Service held on 20 June 1990:

The Committee noted the circulated paper dealing with plans for testing blood donations for Hepatitis C. It was likely that up to 100,000 tests per annum

<sup>405</sup> Management Board Meeting – Circulated PES Document [SNB.002.7426] at 7430–31

<sup>406</sup> Day 69, page 121

<sup>407</sup> Ibid, page 141

<sup>408</sup> Memo [SGH.002.7930]

would be needed at a cost of £1.3 million. Should testing be started during the current financial year, funding would have to come from the contingency fund because there would be no additional finance available from Scottish Home and Health Department.<sup>409</sup>

**31.284** Mr Tucker explained in his statement that when the CSA received its annual budget allocation, 10% of each Division's budget would be held in reserve as a 'contingency fund'. Each element of the contingency fund was, however, related directly to the head of expenditure for which the PES bid had been made and was held in reserve for that head of expenditure. For example, the 10% of the budget for ambulances was held exclusively against any emerging needs of the ambulance service. The contingency fund was not available against unbudgeted expenditure generally.

**31.285** Mr Tucker thought it was very unlikely, if screening had been introduced early, that the CSA could have 'raided' the contingency fund. If there was a good case for urgent funding to be found, the CSA would have examined its financial priorities in divisions other than the SNBTS and looked for any unspent money that could be utilised.<sup>410</sup> If this was not possible the CSA could turn to the SHHD for unspent budgets. If this proved impossible, the request for funding for screening would 'go up the scale'<sup>411</sup> to the Scottish Office Finance Division to see if there was unspent money from a division such as Transport if, for example, a planned roads project had not gone ahead.<sup>412</sup>

**31.286** There were different views. In contrast to Mr Tucker, Mr Roderick Angus commented in his statement:

As part of the Public Expenditure Survey outcome, the Common Services Agency, of which the SNBTS was a division, was provided with a sum of money to be used as a 'contingency fund' to meet any in-year funding needs, this was also referred to as a reserve in some correspondence. Mr Donald, General Manager of the CSA, would have, in the first instance, been expected to fund the testing from within that 'contingency fund' rather than seeking additional funds from the Scottish Home and Health Department.<sup>413</sup>

**31.287** He went on to say that the minutes of the CSA Management Committee 'indicate that had screening been introduced before the financial year 1991–92, it could only have been paid for from the reserve'. If the contingency fund had been insufficient, additional funds could have been requested from Finance Division.<sup>414</sup>

**31.288** Mr McIntosh commented in his statement that the Inquiry's assumption, as reflected in the question, that the contingency fund was the only source of funds for screening was 'probably not correct'.<sup>415</sup> If it had been deemed necessary, Ministers could have brought implementation forward into the financial year of 1990–91. He thought it could have been financed in a number of ways which would probably include the use of the reserve fund. He felt confident that if the introduction of testing had been prioritised in the financial year 1990–91, the money for implementation would have somehow been

<sup>415</sup> Mr McIntosh's Statement [PEN.017.2126] at 2132

found for implementation before 1 April 1991. Mr McIntosh confirmed his view in oral evidence that he did not believe that finance was in fact an obstacle in Scotland.<sup>416</sup> He added that the SNBTS was not encouraged to think budgets were flexible, but he had found 'serious' amounts of money out of similar financial arrangements when necessary.<sup>417</sup>

**31.289** Another witness, Mr David Hogg (SHHD) commented in his statement:

Had the Hep C Testing commenced, however, within 1990-91 then technically the CSA/SNBTS would have to have funded from the remaining Revenue Allocation, including the 'Contingency Fund', although I am sure we within the Health Department would have gone back to Finance Division with a further in-year increased funding bid.<sup>418</sup>

**31.290** In the end, having regard to the evidence as a whole, it appears highly unlikely that funding in Scotland would have depended on technical budgeting issues: if a decision had been taken to commence screening for anti-HCV in Scotland in 1990–91 then the funds would have been found.

### **Start date becomes 1 July 1991**

**31.291** On 13 February 1991 Mrs Falconer (SHHD), sent a handwritten memo to Mr Hogg.<sup>419</sup> She commented that she had spoken to Ms Elaine Webb at the DoH and was advised that 'officially no date has been given'. The date would be discussed at the ACVSB meeting on 25 February, but confidentially the start date was hoped to be 1 July. Ms Webb had commented that 'the Department of Health did not want SNBTS or anyone outwith the office informed'.

**31.292** Mrs Falconer suggested in her Inquiry statement that it may have become effectively a matter of protocol. She observed:

I would suggest that DoH(E) colleagues requested that the 'unofficial date of 1 July' should not be shared because it would not be appropriate to suggest that a possible date had been set before the Advisory Committee had had an opportunity to discuss the matter at its meeting and agree a recommendation.<sup>420</sup>

**31.293** As her conversation with Ms Webb took place just 12 days before the ACVSB met, this appears to be a plausible explanation for the date remaining confidential until the committee had the opportunity to endorse it.

**31.294** Mr Tucker offered a different explanation for this, however. He said that Ms Webb at the DoH was a junior staff member who had inadvertently given an official start date to her SHHD counterpart and tried to mitigate this by saying the SNBTS should not be told. She may also have been concerned the date could be forwarded to the NBTS via the SNBTS.<sup>421</sup>

**31.295** Mr Hogg made an observation in his statement on the subject of why the start date was not to be openly discussed. He observed that the date 'must have been subsequently

confirmed at the aforementioned ACVSB meeting, as in D McIntosh's (SNBTS) letter to Dr McIntyre dated 12 March 1991 ... he clearly states 1 July 1991 as the agreed introduction date!'.<sup>422</sup>

**31.296** On 14 February 1991, Professor Cash advised Dr Habibi (Medical and Scientific Director, National Blood Transfusion Centre, France) that 'we (UK BTS) expect to start HCV donation screening in the early summer 1991 ...'.<sup>423</sup>

**31.297** On 15 February Dr Gunson wrote to the Directors in England and Wales to advise that screening would begin on 1 July 1991.<sup>424</sup> He warned that, if the Gulf war continued and blood donation levels were still very high, this date might have to be reconsidered. There were still matters to be considered at the meeting of the ACTTD on 25 March.

**31.298** Professor Cash wrote to Dr Gunson on 15 February, again saying he would like the SNBTS to stay in line with the NBTS/BPL.<sup>425</sup> Professor Cash asked for a common understanding of what a 'start date' meant. He suspected Dr Gunson would have to pursue Dr Metters' committee (the ACVSB) on these topics.

### Further slippage in timescale for introduction of screening

**31.299** Mr McIntosh described the period between the making of the decision to introduce screening (ie in late 1990) and the end of March 1991 as including 'genuine professional deliberation, aimed at investigating the validity, accuracy, reliability and operational practicality of available test materials and methods'. He thought this investigation was completed in time for anti-HCV testing to have been implemented throughout Scotland by 1 April 1991.<sup>426</sup> Funding for screening had been granted to the SNBTS and was in place for that date.

**31.300** On 21 February, Mr Mark Fuller from the DoH wrote to Dr Contreras.<sup>427</sup> The letter was copied to various individuals, including Dr Gunson and Dr Mitchell. At the meeting of the ACVSB on 21 November 1990, Dr Gunson reported that Ortho had brought out a second generation test, and had offered 2500 free test kits for use on frozen samples held at the North London Transfusion Centre.<sup>428</sup> Mr Fuller's letter was headed 'DH sponsored second round evaluation of HCV screening kits North London BTS, Colindale', and appears to have taken up this project. Dr Contreras was asked whether she was happy for the work to be done at her Centre. The letter does not specifically state that there was to be an evaluation of Ortho second generation kits. However, the instructions were given by Dr Gunson and the context supports the inference that they followed from the intimation in November. Professor Cash was of the view, stated in oral testimony, that this represented evidence that a decision had been made by the DoH to carry out an evaluation of second generation kits, before HCV screening of blood donors was introduced.<sup>429</sup> This is discussed further below.

<sup>428</sup> Meeting Minutes [SNF.001.1777] at 1779

<sup>429</sup> Day 82, pages 24–25

**31.301** The ACVSB met on 25 February 1991.<sup>430</sup> Dr McIntyre attended as the SHHD observer. Dr Gunson did not attend and offered his apologies. The tri-centre study (North London, Newcastle and Glasgow) of the first generation Ortho and Abbott ELISA kits had been conducted in the second half of 1990 and a summary of the results of Phases I and II, dated February 1991, was presented to the committee.<sup>431</sup> All three centres reported that the tests were easy to perform. The Ortho tests were producing more initial screen positives than Abbott, but the repeatable positive rate was similar with both tests.<sup>432</sup> Dr Mortimer again reported results from the continuing pilot study. Significantly, he advised retention of the samples collected, for the evaluation of other candidate HCV tests, and that 'the Committee may wish to see the results from the second generation Ortho and Abbott tests'.<sup>433</sup> Professor Tedder tabled a paper which led to discussion:

The Committee discussed the likely availability of the second generation tests and operational factors which might influence the decision by RTCs as to which screening test to choose .... Members agreed it was important for proper evaluation of the Ortho and Abbott 1&2 tests to be carried out before RTCs decided which test they would adopt.<sup>434</sup>

**31.302** The Chairman's summary noted agreement on retention of the samples and that:

Any new test should be evaluated against the full 10,000 specimens to ensure it was at least as good as the tests already evaluated.

Ortho and Abbott 1 and 2 should in principle be available among others from 1 July for RTC's to choose.<sup>435</sup>

**31.303** The minutes do not record a change in the date participants had in mind for implementation of screening.<sup>436</sup> However, there was a clear weakening in commitment to any particular date, in so far as it was agreed that it was important for proper evaluation of the Ortho and Abbott 1 and 2 tests to be carried out before the RTCs decided which test to adopt, and availability of these tests 'in principle' by 1 July further qualified commitment.<sup>437</sup> The idea of an evaluation, incorporating second generation tests so that the RTCs could decide which to adopt, appears to stem from this meeting.

**31.304** However, that idea was not immediately appreciated. On 26 February Mr Bayne and Mr Panton of the SHHD met with Dr McIntyre<sup>438</sup> who had attended the ACVSB meeting of 25 February.<sup>439</sup> Dr McIntyre had confirmed the start date for screening was to be 1 July. Mr Bayne prepared a note of the meeting recording, in particular, that start date.<sup>440</sup>

<sup>430</sup> Meeting Minutes [SNB.001.8934]

<sup>431</sup> [PEN.016.0028] The final report was not available to the Inquiry when the Preliminary Report was written. Phase I results were discussed at ACVSB on 21 November 1990.

<sup>438</sup> The Extended Narrative [PEN.017.2165] mistakenly records this meeting as being with Mr McIntosh of SNBTS.

<sup>439</sup> Handwritten notes re: date of commencement for HCV testing [SGH.002.7880] and [SGH.002.7881]

<sup>440</sup> Note [SGH.002.7881]

**31.305** On 12 March 1991 Mr McIntosh wrote to Dr McIntyre on the topic of the 'Introduction of HCV testing'. Mr McIntosh referred in his letter to the 'agreed national (UK) introduction date (1 July 1991)'.<sup>441</sup>

**31.306** In a handwritten memorandum apparently dated 19 March, a message was sent by Mrs Falconer (who worked in the same Branch as Mr Panton)<sup>442</sup> to Mr Hogg. It noted the date of commencement of testing as 1 July 1991 and queried 'What about submission?'. She suggested he read the note of the meeting with Dr McIntyre and Mr Panton, written by Mr Bayne. The tone of her note suggested that the submission to the Minister had not yet been drafted. This prompted a note, of the same date and handwritten on the same document, from Mr Hogg to Mr Panton: 'To see and discuss next steps re the submission'.<sup>443</sup>

**31.307** In addition, this document contains a note that appears to be in Mr Panton's handwriting: 'Draft submission based on English one – shorter version. Other Ministers have agreed'. While the note is ambiguous, and might mean that a submission had already been drafted as a shorter version of the English submission, it is more likely to have been a drafting instruction along the lines suggested. Mr Tucker suggested in oral evidence that it was an instruction.<sup>444</sup> In his statement, Mr Hogg stated that he viewed it as an instruction that Mr Panton had addressed to him.<sup>445</sup> It reflected the reality of the relationship between the SHHD and the DoH: advice to Scottish Office Ministers needed only to be based on the text of the DoH submission. There was no independent input required.

**31.308** On 21 March 1991, the marketing manager of Ortho wrote to Professor Cash to advise that the second generation ELISA test was to be introduced, replacing the first generation test.<sup>446</sup> On the same day, the NHS Procurement Directorate sent a letter (possibly implementing the decisions of the ACVSB made at the February meeting) to Dr Gunson in respect of a phase two evaluation of the HCV screening tests. The letter stated:

The Department has agreed that there should be a 'second-round' comparative evaluation of Hepatitis C kits at the Newcastle, North London and Glasgow Regional Transfusion Centres ....

The work to be carried out by the NBTS should start in February for the North London RTC and March for the other centres and be completed by the end of April. After this any repeat positive samples previously not identified will be sent to the reference laboratory for additional (and confirmatory) testing.

In consideration of the work to be carried out in Phase II the approved limit of expenditure ... shall be by quotation to Mr Fuller, from each of the centres .... The screening kits involved in the evaluation have been ordered from, Ortho Diagnostic Systems, Organon Teknika and UBI ....<sup>447</sup> Tests from Abbott Laboratories will be done at Newcastle & Glasgow when available, the other tests being only done at North London.<sup>448</sup>

<sup>448</sup> Letter [SNB.006.3953]

**31.309** As discussed below, just two days later, on 23 March, Dr Gunson telephoned Professor Cash to say that the commencement date for anti-HCV screening would be postponed. It is difficult now to understand why this should have been the case given that the letter from the Procurement Directorate expected the further evaluation to be completed by the end of April. Professor Cash could not explain this when asked in oral evidence. He observed, however, that the letter of 21 March to Dr Gunson from the Procurement Directorate, while very positive in tone, was from people who would not have 'the faintest idea' whether or not the kits were available. According to Professor Cash, Dr Gunson told him later the unavailability of second generation tests emerged as one reason for the delays.<sup>449</sup>

**31.310** The letter from the Procurement Directorate does refer to a March start for the evaluation in the Newcastle and Glasgow centres, in contrast to a February commencement in North London, suggesting a delay in the delivery of Abbott kits. In addition the letter makes reference to the Abbott kits being used at the Newcastle and Glasgow centres 'when available', possibly suggesting there was also a delay anticipated in the delivery of those kits. As noted above, Ortho's injunction against Abbott supplying further kits continued until 14 April, and this may have been the explanation for the anticipated delay. The evaluation was, however, expected to be finished by April and therefore would have been completed in time for a 1 July start date.<sup>450</sup>

**31.311** The general issue of delaying implementing a new screening test until a later generation of the test was available, was explored with Professor Leikola in his evidence to the Inquiry. Professor Leikola did not consider it necessary generally to delay the introduction of a test on the basis that better kits were on the horizon. In oral testimony he expressed the view that one would start screening with what was available and introduce better tests when they arrived. He did not think that time would be lost in the transition if a country had brought in screening with early test kits, and later replaced them with new and better kits.<sup>451</sup>

**31.312** He was asked if there was much work and time involved in introducing a second generation test to a laboratory which was already carrying out first generation testing. Professor Leikola thought that if the tests were basically similar, and did not require totally new machinery, it would not be difficult to do comparative tests on the two generations of kits to ensure the sensitivity and specificity had truly improved. He went on to say that the practicalities of actually introducing the new test would take time. First, the authorities would have to consider whether the manufacturer would be able to deliver enough of the new test kits. Secondly, work would be required to amend the legal agreements with the manufacturers of the first test, if necessary.<sup>452</sup>

**31.313** Professor Leikola's view was that, generally speaking, if newer, better kits were becoming available for use, the transition should have been made as soon as possible. Deciding not to introduce the old test because the new one was imminent could only really be justified if the manufacturer was very close to releasing the second generation test. If the new test would be only marginally better, there would be less urgency to introduce the second test.<sup>453</sup>

### The phone calls of 23–24 March 1991

**31.314** Three telephone conversations regarding the postponement of the introduction of screening featured in evidence given to the Inquiry by Professor Cash. His was the only evidence available, and it became clear that the events were highly emotionally charged. Precise recollection cannot be expected. The first of the phone calls was made by Dr Gunson to Professor Cash at his home, on Saturday 23 March. The general topic of conversation was the upcoming meeting of the ACTTD on the following Monday, in Manchester.<sup>454</sup>

**31.315** According to Professor Cash, the first phone call was ‘very acrimonious and distressing’. Professor Cash did not know that the DoH in London had decided there would be another ‘field trial’, this time on the second generation kits. He had understood from Dr Mitchell that evaluation of the second generation kits would be fitted in after the commencement of screening (using first generation kits) on 1 July, but Professor Cash then realised that another month would go by while this kit was evaluated, and he objected to the plan. Professor Cash recalled that Dr Gunson repeatedly claimed that the Scottish Office ‘were party to this decision’.<sup>455</sup> What precisely the Scottish Office was party to was explored in oral evidence with Professor Cash; he did not know if ‘on board’ meant with the carrying out of an evaluation of second generation tests, or ‘on board’ with the postponement from July to September.<sup>456</sup>

**31.316** Professor Cash was later asked in oral evidence why he did not confirm the SHHD position with them directly. He reiterated that, regrettably, ‘Harold Gunson convinced me that SHHD had been party to the decisions that were made’.<sup>457</sup>

**31.317** Professor Cash recalled in oral evidence that Dr Gunson had been instructed to make certain that a trial of the second generation tests was agreed, and plans put in place by the time of the committee meeting on the Monday morning. The change of intention was that screening would not commence in July and instead there would be another field trial. According to Professor Cash, the idea had been abandoned, that evaluation of second generation tests could be fitted in after screening commenced on 1 July.<sup>458</sup> Professor Cash added that he had initially refused to go to the ACTTD meeting on Monday and comply with Dr Gunson’s wishes. This created ‘acrimony’ between the two friends.<sup>459</sup>

**31.318** Professor Cash told the Inquiry his initial reaction was to say, ‘We don’t need to delay at all’. In his view, other first world countries were starting to screen donors for anti-HCV using the first generation kits. Professor Cash was particularly concerned that the first generation kits would soon be unavailable as the manufacturers would withdraw them.<sup>460</sup>

**31.319** Dr Gunson telephoned Professor Cash again. According to Professor Cash’s recollection of this conversation, it became increasingly clear to him that Dr Gunson was ‘under extreme pressure to deliver a second generation field study and in doing so delay the onset of testing’. Dr Gunson agreed to send documents to Professor Cash that

<sup>454</sup> Day 82, page 6

<sup>455</sup> *Ibid*, page 7; also Day 72, page 166

<sup>456</sup> *Ibid*, page 21

<sup>457</sup> *Ibid*, page 76

<sup>458</sup> *Ibid*, page 9

<sup>459</sup> *Ibid*, page 10

<sup>460</sup> *Ibid*, page 11

indicated the Department had signalled that this work was necessary. It was not a decision of the Advisory Committee. In Professor Cash's words: the Advisory Committee had been 'bypassed'.<sup>461</sup>

**31.320** During the second call, Dr Gunson gave Professor Cash an assurance that the NBTS directors would 'keep in line' with regard to delaying screening to allow for evaluation of the second generation tests. Apparently Dr Gunson had assured him that, 'if anyone got out of line at all, or thought about it, DoH would come down on them like a tonne of bricks'.<sup>462</sup> It emerged in the call that a fundamental problem south of the border was one of 'funding and agreeing that funding system'. This was not a problem in Scotland. The funding situation in England was a deep-seated problem that Dr Gunson communicated to Professor Cash in the second telephone call.<sup>463</sup> As already noted, the funding problem in England was not new: it had been recognised but left unresolved for over a year.

**31.321** After further reflection Professor Cash telephoned Dr Gunson that Sunday, 24 March, to say he would agree to participate and that he would support Dr Gunson at the meeting in Manchester the next morning. He added it had been 'a matter of great regret to me ever since' that he did not insist that the whole of the UK should start implementing testing with first generation kits in the way other countries had done. Dr Gunson had told him that Dr Mitchell was 'on board' with the plan.<sup>464</sup>

**31.322** Professor Cash was asked how Dr Gunson knew that Dr Mitchell was 'on board'. He answered that Dr Mitchell had been copied into the letter he had received from the Procurement Directorate dated 21 March from Dr Gunson announcing a second generation study.<sup>465</sup>

**31.323** Professor Cash told the Inquiry in oral evidence that this became a 'painful' and 'personal' issue between him and Dr Gunson. He added:

Harold insisted that this was a device to give the Department of Health more time, more space, to resolve these very difficult financial problems that they had, and secondly, he insisted – this became very heated – that SHHD knew all of this and ... this is about the second generation evaluation, and the moment you sign up to that, July has gone.<sup>466</sup>

**31.324** Dr Gunson was unable to explain to Professor Cash why they could not just absorb the second generation tests after they had started using the first generation kits. Professor Cash came to his own independent conclusion that the DoH had 'devised a way' that gave them more time to sort out the funding problems in England and Wales. Professor Cash claimed to have discussed that with Dr Gunson, who did not deny it was a possibility but did not know for certain. Dr Gunson was, on Professor Cash's account, simply carrying out instructions.<sup>467</sup>

<sup>467</sup> Day 82, page 19

*Device of a further study*

**31.325** There appeared to the Inquiry to be two separate issues. First, there was the matter of postponing the start date because the English centres were not going to be ready due to funding problems. The second issue was a desire to do an evaluation of second generation kits, which would inevitably cause delay. Professor Cash was adamant the two were linked. His contention was that the evaluation of the second generation tests was promoted by Department of Health civil servants to buy more time to 'cover up' the fact that English centres were not going to meet the 1 July deadline because the funding was lacking. Professor Cash suggested the evaluation of second generation kits was used as a 'device' to justify the delay.<sup>468</sup>

**31.326** Professor Cash was asked if there was any reason why it was not possible to start screening using the second generation kits and thus to assemble evidence on how they performed. He agreed that it should have been possible. He thought that 'was done readily by half the world'.<sup>469</sup>

**Meeting of the ACTTD on Monday 25 March**

**31.327** Following the three distressing telephone calls between Professor Cash and Dr Gunson on 23 and 24 March 1991, Professor Cash said they had 'fallen out badly' but 'fell in again' shortly afterwards. Professor Cash, with 'some reluctance,' agreed to attend the meeting of the ACTTD on the following Monday (25 March) and not object to the second generation kits study and the delay in the introduction of testing.<sup>470</sup>

**31.328** The meeting of the ACTTD duly took place on the Monday.<sup>471</sup> At point 4.11 the minutes record:

The proposed starting date of 1st July presented difficulties since it was considered essential that the second generation test from both Ortho [*sic*] and Abbott should be evaluated prior to the commencement of routine tests.<sup>472</sup>

**31.329** There was reference to difficulties with the availability of both Ortho and Abbott second generation test kits. There was no official date for the launch of the second generation kit from Abbott.<sup>473</sup>

**31.330** There was an acknowledgement that 1 July looked difficult as a start date, but the minutes of the meeting did not go so far as to suggest a new date. There was a reference to Dr Gunson contacting Abbott to find out their availability date and then recommending a start date for the commencement of tests. There is no reference in the minutes to funding issues in England and Professor Cash could not recall if it was discussed.<sup>474</sup> However, as noted above, when Dr Gunson wrote to Professor Cash on 28 January, and in later exchanges, it was taken as common ground between them that for England and Wales there was the matter of financial provision to be sorted out.<sup>475</sup>

<sup>468</sup> Day 72, pages 167–68

<sup>474</sup> Day 82, page 47

<sup>475</sup> Letter [SNB.004.4574]: see paragraph 31.267 above

**31.331** There is no reference in the minutes to ‘decoupling’ the second generation evaluation from the actual commencement of testing. There is also no suggestion that, given the problems with the availability of second generation kits, the UK should screen using available first generation kits and evaluate the second generation kits afterwards.<sup>476</sup>

**31.332** Professor Cash’s position in oral evidence was that he did not suggest to the ACTTD that screening should start on 1 July with second generation evaluation being fitted in later, as he had promised Dr Gunson he would not say anything about it at the meeting.<sup>477</sup> It was put to Professor Cash during his evidence that the minutes of the meeting of the ACVSB on 25 February 1991 suggest that it was the ACVSB that had decided that there should be an evaluation of the second generation kits and that that should happen before transfusion centres decided which test to adopt. Professor Cash disagreed with that proposition, however. He believed that the mechanism by which evaluation of the second generation kits would take place before transfusion centres decided which kit to use, was achieved and delivered by this meeting of the ACTTD.<sup>478</sup>

**31.333** Professor Cash wrote a letter to Mr McIntosh dated 27 March 1991<sup>479</sup> following the ACTTD meeting and copied it to Dr McIntyre at the SHHD and to the Transfusion Directors. The letter stated that it was clear the NBTS was struggling to meet the 1 July commencement date and Professor Cash believed there was a fundamental problem with financial resources. Dr Gunson was to tell the DoH that the 1 July start date should be delayed until such time as an evaluation of the second generation HCV screening tests had been completed. If that was accepted it could push the start date to September. The impression created by Professor Cash’s evidence was that this would be an indication that the recommendation to postpone had the backing of medical professionals.

**31.334** Professor Cash stated in his letter that both he and Dr Mitchell supported the proposal that the start date should be pushed back to September. He explained in oral evidence that this was what he had agreed with Dr Gunson on the telephone that he would do.<sup>480</sup>

**31.335** Mr Panton added a handwritten comment to Mr Hogg on this letter to say that this was a ‘worrying’ development: they could not go to the Scottish Minister until they knew the start date. It appears to the Inquiry that this letter was the first indication that the SHHD had received that there was a problem with the proposed start date and a plan to postpone the introduction of screening.<sup>481</sup>

**31.336** Mr Tucker commented in his statement that there was no doubt in his mind that the Scottish Minister would have supported what was agreed by the English Ministers: ‘This would have been the case irrespective of when our minute was submitted’.<sup>482</sup>

**31.337** With regard to NHS financial problems in England and Wales, Mr McIntosh told the Inquiry in oral testimony that he could not recall any briefings about this issue. He felt this backed up his ‘secondary theory’ that there were issues about money. Professor Cash was suggesting that he was aware at the time that the English were not implementing

testing because of financial restraints in the regions, but was still encouraging Scotland to hold back and follow the 'party line'.<sup>483</sup>

### End of March to September 1991

**31.338** Mr McIntosh described this period from late March to the end of August 1991 as including discussion of further validation and testing, but in reality creating successive delays in full implementation due to dedication to 'UK solidarity'. He commented in his statement that:

[T]he successive delays from 1<sup>st</sup> April through to 1<sup>st</sup> September were not made necessary by any considerations as to what would be best for patients in Scotland nor indeed by any Scottish issues. They were exclusively – rightly or wrongly – a direct result of the UK solidarity argument prevailing over other opinions.<sup>484</sup>

**31.339** He said that there was a group of Regional Transfusion Directors in the SNBTS who favoured implementation as soon as possible. They were opposed by people who were members of the 'UK solidarity camp', as he described them, and who were firmly of the view that all parts of the UK should implement testing at the same time. According to Mr McIntosh the 'UK solidarity camp' was 'best exemplified' by Professor Cash.<sup>485</sup>

**31.340** In Mr McIntosh's view, there was no real administrative control over the dates of commencement of testing. There was no mechanism for preventing one centre from starting to screen donors before other centres were ready and there was no mechanism for censure of a centre that proceeded before the global start date. Mr McIntosh commented that if there had been control it would have been exercised in reaction to the unilateral commencement of testing by the Newcastle centre discussed below.<sup>486</sup> The only censure that the Inquiry is aware of was the suggestion, made by Professor Cash, of the exclusion from national committees of the head of the Newcastle centre, Dr Lloyd.<sup>487</sup>

**31.341** On 3 April 1991 Dr Gunson wrote to the Regional Transfusion Directors in England and Wales (and copied in Professor Cash) to advise it would not be possible to introduce testing on 1 July.<sup>488</sup> It had not been possible to start the evaluation of the second generation Ortho and Abbott tests. One of the kits would not be available until later in April. The schedule would be too tight if the transfusion services tried to evaluate the second generation test, and commence screening on 1 July. It was difficult to give a precise date for the commencement of screening, but Dr Gunson thought they should aim to start by 1 September.

**31.342** On 3 April 1991 Mrs Falconer was asked in a handwritten memorandum by David Hogg to 'Please check with DOH if they have considered a new start date ... and if they could advise us accordingly before we go to the Minister'.<sup>489</sup> On 4 April Mrs Falconer sent a handwritten note to Mr Hogg to say the DoH was considering a new start date of 1 September 1991, but the date had not yet been finally agreed.<sup>490</sup>

<sup>489</sup> Memo [SGH.002.7877]

<sup>490</sup> Handwritten note [SGH.002.7876]

**31.343** On 4 April, Dr Gunson wrote to the NHS Procurement Directorate in response to their letter of 21 March (as referred to in paragraph 31.308), above. The letter bore the heading 'Comparative evaluation of hepatitis C kits – phase II' and stated:

The timing of this study has slipped because of the unavailability of test kits. The Ortho 2nd generation tests have only arrived at North London RTC within the past few days and it is unlikely that the Abbott test kits will be available until the middle of April.<sup>491</sup>

**31.344** Dr Gunson stated in his letter that Dr Metters had agreed with him that the introduction of testing could be delayed until 1 September. In his evidence to the Inquiry Mr Tucker expressed the opinion that Dr Gunson appeared to be taking the decision himself.<sup>492</sup>

**31.345** On 5 April, Professor Cash replied to Dr Gunson's letter of 3 April and confirmed that, 'My colleagues would wish you to know that this most recent development, leading to a start date in September 1991, has the SNBTS Directors' fullest support'.<sup>493</sup>

**31.346** When pressed on the first occasion he gave oral testimony on this matter, Professor Cash conceded it was 'very probable' that he had written and recorded the support of his fellow directors without having specifically asked them.<sup>494</sup> On the second occasion he gave oral evidence, Professor Cash was adamant: 'I cannot imagine ... that I hadn't in some way consulted with my colleagues'.<sup>495</sup> He added later in oral evidence, 'I can't imagine I would have written it without ringing ... just to find out their views'.<sup>496</sup> The Inquiry notes that Professor Cash's letter of 5 April was not copied to the SNBTS Directors.

**31.347** On 11 April the DOH faxed Mrs Falconer (SHHD) the draft of a proposed letter, EL(91), to the Regional Health Authorities in England and Wales.<sup>497</sup> It stated:

Ministers have agreed that screening of blood and plasma for HCV should be introduced as a public health measure now that suitable tests are available .... No date for the introduction of routine testing has yet been fixed but this is unlikely to be before 1 September 1991. You will be informed as soon as a date has been agreed .... No additional [funding] allocation will be made for the cost of testing in the HCHS budget for 1991-92 and Regions will have to meet the increased blood handling charges from their general allocation. The Department is negotiating a national maximum contract price for testing kits. Further details of this will be made known as they become available.<sup>498</sup>

**31.348** On 15 April, Mrs Falconer sent a note to Mr Hogg: 'Please see para 11 of draft DOH EL(91) which shows proposed date for introduction of HEP C screening not yet fixed but unlikely to be before 1 Sept 1991. Can we now put forward submission?'.<sup>499</sup>

<sup>499</sup> Note [SGH.002.7864]

***Newcastle starts screening***

**31.349** On 30 April there was an SNBTS/NBTS Liaison Committee meeting.<sup>500</sup> It was suggested that a commencement date of 1 September would be appropriate. Dr Gunson reported that the general manager at the Newcastle Transfusion Centre, Dr Huw Lloyd, had commenced testing in the last week. There was no confirmatory testing being carried out and it was not clear whether positive donors were being counselled. Mr McIntosh immediately informed SHHD officials about these events. Dr Gunson had already advised the DoH of the same and 'advice was awaited'. Dr Gunson hoped to establish multi-centre evaluation of second generation kits with Newcastle as a participating centre. He expected an SNBTS centre would contribute to the evaluation.

**31.350** The minutes of the Liaison Committee meeting go on to note that '[i]t was agreed that a firm clarification of policy was urgently required from DoH/SHHD within 7-10 days'.<sup>501</sup> It is not clear on the face of the minutes whose responsibility it was to carry out that task as no initials appear next to that section of the minutes.<sup>502</sup> When questioned later in oral evidence, Professor Cash commented that 'Harold would have gone back to [the DoH] .... David would go to the Scottish Office. Looking at seven to ten days, that's miraculous timing'.<sup>503</sup>

**31.351** Professor Cash could not recall if there was an attempt within that limited period of time to get clarification of a policy from the SHHD. He did not know if Mr McIntosh had gone to the Scottish Office to request clarification.<sup>504</sup>

**31.352** Dr Lloyd of the Newcastle centre wrote to all Directors of the transfusion services on 2 May 1991 and copied his letter to Dr Gunson and Professor Cash.<sup>505</sup> In his letter Dr Lloyd stated that as Newcastle was already set up for testing, he had decided to keep to the July implementation date. His personal view was that to not test when there was the ability to test would be 'indefensible under the current Product Liability Legislation'. He commented: 'By 1st July all units of blood for transfusion in the Northern Region will be negative for Hepatitis C antibody'. There was a lead-in time to ensure all products were tested by 1 July, which Dr McClelland pointed out in oral evidence related to the shelf life of these products.<sup>506</sup>

**31.353** Dr Lloyd's letter generated a number of responses from other Transfusion Directors. On 7 May, Dr Mitchell wrote to Dr Lloyd with a hint of concern that screening had commenced so far ahead of the results of the evaluation tests. Dr Mitchell added that he presumed Dr Lloyd had 'started using the most appropriate test which you have validated on the results of the current three Centre evaluation of the 2nd Generation tests'.<sup>507</sup>

**31.354** Professor Cash wrote a letter about 'solidarity'<sup>508</sup> to Dr Lloyd on 7 May to express his 'profound dismay' at this turn of events.<sup>509</sup> The letter stated that Dr Lloyd's unilateral introduction of testing was both 'disgraceful and mischievous'. Professor Cash stated,

<sup>500</sup> Meeting Minutes [SNB.010.1108]

<sup>501</sup> Ibid [SNB.010.1108] at 1110

<sup>502</sup> Day 82, page 90

<sup>508</sup> Day 82, page 74

<sup>509</sup> Professor Cash's letter [SNB.011.8726]

whilst giving oral evidence, that he now regretted writing his letter to Dr Lloyd.<sup>510</sup> He added that, looking back, he 'shouldn't have sent it, period, full stop'.<sup>511</sup> Professor Cash did not ever believe Dr Lloyd's actions had been correct however.<sup>512</sup>

**31.355** Dr Lloyd wrote back to Professor Cash on 9 May. He personally believed that to start HCV testing according to the original schedule was the correct decision, even if others found it unpalatable.<sup>513</sup> He went on:

To suggest that my action was ... "mischievous", is to impart motives to this action that were not mine. If you wish to question motives, then perhaps you should be asking why a vague September start date has replaced with little explanation, a firm date in July.

**31.356** On 9 May 1991 J C Dobson, DoH, sent an internal memorandum by fax to a DoH official with copies to Dr Metters and others:

1. You will wish to be aware of a potential difficulty over screening for hepatitis C in blood donations, which may be picked up by the press.
2. Ministers decided earlier this year to authorise the routine screening of all donated blood for the hepatitis C antibody. After discussion within the NBTS a start date of 1 July was agreed but this was later delayed to allow evaluation of the "second generation" test kits. Despite this, the Northern Regional Transfusion Centre made a unilateral decision to start screening from late April.
3. Press interest is likely to focus on the prospect of the other Regions using untested blood, and may attempt to link it with the current interest in the settlement for haemophiliacs who were infected with the AIDS virus and the recent claims for compensation by people infected with HIV through blood transfusion.
4. I attach a background note and a line to take.<sup>514</sup>

**31.357** The memo by J C Dobson was also sent by fax to the SHHD, and in a handwritten note dated 8 May Mr Panton advised Mr Hogg: 'I have discussed this with Mr Tucker. We should put our submission forward about the 1 Sept start date and incorporate this: – Northern jumped the gun etc. Line to take for media enquiries'.<sup>515</sup>

**31.358** Dr Lloyd wrote a conciliatory letter in response to Professor Cash on 4 July. The two had met and mended their differences. Dr Lloyd expressed his concern that the UK was dragging its feet with regard to testing. Some of his staff had been concerned at the tone of the initial letter Professor Cash had written on 7 May and how it affected them.<sup>516</sup>

**31.359** Professor Cash wrote to Dr Lloyd for the last time on this topic, on 19 July.<sup>517</sup> He emphasised the importance of the 'team approach' and the risk of exclusion if Dr Lloyd did not adhere to the team mentality. Professor Cash expressed his concern at the

<sup>515</sup> Handwritten note [SGH.002.7854]

<sup>516</sup> Dr Lloyd's letter [SNB.004.5732]

<sup>517</sup> Professor Cash's letter [SNB.011.7806]

'continued Balkanised mentality of BTS in England and Wales'. Dr Lloyd intended to be in Edinburgh the next month and Professor Cash invited him to take the 'opportunity of apologising ... to the SNBTS Directors'.<sup>518</sup> Professor Cash, in oral evidence, admitted to some regrets about this letter. He added that Dr Lloyd did not accept the invitation to apologise personally to the SNBTS directors.<sup>519</sup>

### *Consideration of earlier start in Scotland*

**31.360** Dr McClelland was asked about the position in Scotland, and the possibility of similarly going ahead with screening more quickly. He was uneasy about the delay in commencement and said in his statement that there 'certainly was consideration of an earlier start'. He recalled that the introduction of screening had been at the meeting of the SNBTS directors on 11 and 12 June 1991.<sup>520</sup>

**31.361** On the same theme, Dr Perry commented in oral evidence that in a practical sense it would have been possible for different parts of the UK services to have commenced testing at different times. He thought 'it would have been possible ... for the SNBTS to have gone ... on the original date of April'. He added: 'But underpinning the whole exercise was this UK common start date'.<sup>521</sup> From a 'practical and political perspective' it would have been impossible; the SNBTS would not have had the authority from the SHHD or the Department of Health.<sup>522</sup>

### *Public presentation of the further study*

**31.362** On 8 May 1991 Professor Cash faxed a letter to Dr Gunson in the immediate aftermath of the Newcastle decision. He suggested a national large-scale validation study, and added, 'We should make every effort to maximise this disaster to our corporate advantage'. It appears from the letter that it follows a previous discussion between the two on how to move on from the Newcastle events. The commencement of testing in Newcastle would be portrayed as a further, continued, study. Phase I would run until 15 July and it would be an exercise to assess the efficacy of the two different second generation kits. Phase II would run from 15 July to 31 August, in order to collect more screen test positives to assist in more extensive studies. This was described by Professor Cash in his letter as the 'public reason' for Phase II. It would allow the centres participating in the extended trial to continue to screen through to 1 September, and not have a break in between.<sup>523</sup>

**31.363** Professor Cash suggested the Glasgow centre might enter this national study. Glasgow and Newcastle would be the centres testing the Abbott kits and there would be two English centres testing Ortho kits. Professor Cash commented in his letter that Dundee and Inverness would be happy to 'pitch in' using the Ortho tests, but that their donation collections were relatively small and could be a disadvantage to Ortho. Funding was going to be a problem as it was becoming a larger exercise. Professor Cash was going to be on leave, and copied the letter to Dr Mitchell to ensure continuing SNBTS managerial support for Dr Gunson. It was also 'silent copied' to Mr McIntosh for reference.<sup>524</sup>

<sup>522</sup> Ibid, pages 127-128

<sup>523</sup> Dr Cash's letter [SNB.005.1723]

<sup>524</sup> Ibid [SNB.005.1723] at 1724-25

**31.364** In his oral testimony, Mr McIntosh considered whether or not Professor Cash had sought the Board's consent to offer the Glasgow centre into this study. He said:

It's inconceivable that we would have done this in Glasgow without the whole of the SNBTS management board having agreed it and the other RTCs being comfortable. So one has to assume that Edinburgh, Aberdeen, Inverness, Glasgow, Dundee would have known and were content at this time.<sup>525</sup>

**31.365** Despite extensive examination of documents from this short period of time in May 1991 when Professor Cash and Dr Gunson corresponded about which centres should evaluate the second generation kit, it has not been possible to find any documentary evidence that the matter was put before the SNBTS board for consent. It appears that the two National Directors decided together that Glasgow RTC would be one of the centres to take part in the evaluation.

**31.366** There is a reference in Professor Cash's letter of 8 May 1991 to a 'public' reason for Phase II of the study. Professor Cash agreed in oral evidence it could be described as '[A] device. There is no doubt whatsoever'. He did not disagree that this suggested a degree of deception.<sup>526</sup> He claimed his preferred option, in response to the Newcastle events, was for testing to commence in an orderly fashion without sticking rigidly to September as the start date and that Scottish centres could be in the first wave of the introduction.<sup>527</sup> He wanted the Scottish Office to review the situation and give guidance on the next steps: 'it was a policy decision that had to be made by Ministers'.<sup>528</sup> He had no recollection of putting this in writing to the SHHD and the Inquiry has found no evidence of written communication to decision makers at the SHHD from the SNBTS on this particular question.<sup>529</sup>

#### *Arrangements for the further study*

**31.367** On 13 May 1991 Dr Gunson produced a draft protocol including two new English RTCs, entitled 'Extended pilot trial of 2nd generation anti-HCV tests'.<sup>530</sup> The protocol stated:

It is proposed to ask three RTCs in England and one in Scotland to undertake an extended trial of 2nd generation Ortho and Abbott anti-HCV tests. The RTCs using the Ortho tests are Liverpool and Leeds and those using Abbott tests are Newcastle and Glasgow.<sup>531</sup>

**31.368** Also on 13 May 1991, Professor Cash wrote to Dr Gunson (copied to Dr Calman and Dr Metters), in the week following the unilateral commencement of HCV screening in Newcastle. He stated:

It has always been the view in Scotland, both in the Scottish Office and throughout the SNBTS, that the introduction of additional microbiology donation screening tests would be subject to Ministerial approval. Our understanding of this issue goes back many years .... In recent times, evidence

<sup>531</sup> Ibid [PEN.016.0249] at 0250

that Ministers wished to acquire a firmer grip on this activity came with the establishment of the Advisory Committee on the Virological Safety of Blood. This development, in principle, was warmly welcomed in Scotland.<sup>532</sup>

**31.369** On 14 May, Professor Cash wrote to Dr Mitchell at Glasgow Regional Transfusion Centre to 'confirm that Harold Gunson and I have agreed that West BTS should form one of the Abbott wings of the UK BTS Second Generation (HCV) donation testing study'.<sup>533</sup> This study would ensure full donation testing in that region and would continue through to the proposed date for full screening on 1 September. It had been suggested by Dr Gunson that donor counselling would not feature during the study period. It appears that funding was no longer an issue: Dr Mitchell was asked to cost the exercise and let the SNBTS and John Francis (SNBTS, Finance Officer) know the figures.

**31.370** On 14 May Professor Cash sent a long memorandum about HCV testing to the SNBTS Board members in response to an article in *The Sunday Times* of 11 May with the headline 'Victims to sue in new infected blood scandal'.<sup>534</sup> This memorandum appears to be a justification, rather than a request for consent, for evaluating the improved second generation tests as the first generation tests were withdrawn. The memorandum states that:

[R]epresentations are being made, in the light of the developments in Newcastle RTC, as to whether, in future, the SNBTS is bound to a UK BTS approach with regard to donation testing, against a background of Ministerial involvement.<sup>535</sup>

That implied an understanding on his part that the SNBTS had been obliged to adhere to a start date which was the same throughout the UK.

**31.371** On 15 May 1991 Professor Cash wrote to Dr Gunson to thank him for his proposed protocol for the extended HCV trial.<sup>536</sup> Professor Cash expressed his desire to encourage the participants in the extended trial to keep going after mid-July. He acknowledged this would certainly happen in Newcastle. He expressed concern that 'some people (notably David McIntosh!) may get very jittery'. Professor Cash balanced this with his view that the period from mid-July to 1 September would deliver a further batch of screen positive samples. This was described in his letter of 8 May as the 'public reason' for Phase II of the validation study. This would mean that, by the time full screening started, the SNBTS would be in a very strong position with regard to matching data on RIBA and PCR. This in turn would help enormously in the preparation of guidelines for future handling.<sup>537</sup>

**31.372** In oral evidence Mr McIntosh denied the description of himself as 'jittery' at the time.<sup>538</sup> He was certainly 'very concerned', but in May of 1991 the anxiety about the date of introduction of screening had not reached its later heights. The SNBTS was still hoping to proceed quite soon.

<sup>532</sup> Letter [SNB.005.1721]

<sup>533</sup> Letter [SNB.005.1711]

<sup>534</sup> Professor Cash's memo [SNB.005.1717]. *The Sunday Times* article was in fact published on 12 May [SGH.002.7853]

<sup>535</sup> Professor Cash's memo [SNB.005.1717] at 1719

<sup>536</sup> Professor Cash's letter [SNB.005.1707]

<sup>537</sup> Ibid [SNB.005.1707]

<sup>538</sup> Day 70, page 53

**31.373** Mr McIntosh said later in oral evidence that his recollection was:

[N]ot that I got jittery when the news of Dr Lloyd's action became known; I got jittery, and increasingly so, from April onwards because we [SNBTS] were not doing what we ... were encouraged to do, which was to introduce screening as soon as reasonably practicable.<sup>539</sup>

**31.374** On 15 May 1991 Drs Hughes and Macvarish (Glasgow and West of Scotland BTS), reported on their evaluation of the second generation Abbott anti-HCV ELISA.<sup>540</sup>

**31.375** At the meeting of the SNBTS Medical and Scientific Committee on 16 May 1991 it was noted that the best estimate for the commencement of routine anti-HCV screening was 1 September 1991. The minutes confirm that Professor Cash had told Dr Gunson the SNBTS could 'self-fund' the second generation study in Glasgow.<sup>541</sup>

**31.376** Mr McIntosh suggested in oral evidence that the extended trial was a delaying tactic and a 'cover' for the fact that funding was not available throughout the UK. Funding was available in Scotland from April 1991, but not in England. In his opinion England could not afford it so pressure was put on Scotland not to proceed.<sup>542</sup>

**31.377** In practice, as a result of including Glasgow and West of Scotland in the UK Phase II study of anti-HCV testing, nearly half of all SNBTS blood donors were already being screened and would continue to be screened as part of the continuing evaluation exercise, until the commencement of UK-wide routine screening superseded the evaluation. In other words, from some point in May 1991, around 50% of Scottish blood donations was screened for anti HCV due to the West of Scotland Transfusion Centre taking part in the pilot trial of second generation Abbott and Ortho test kits. Anti-HCV positive donations would have been set aside. Dr Perry was not sure what happened to the donors, whether they were simply screened out or told and counselled. He thought that, as the months progressed through 1991, the policy of a common UK start date was becoming harder to reconcile and sustain.<sup>543</sup>

**31.378** The period in 1991 leading up to the introduction of screening was a confused time, according to Dr Perry. There was a confirmatory test in place and the FDA had granted a licence for the Ortho kit. The date for commencement slipped from April to July and then to September, despite a policy decision having been taken by the ACVSB in November 1990 that the UK should introduce HCV screening as soon as practicable, with individual RTCs deciding whether to use the Ortho or Abbott test. The appearance of the second generation tests in early 1991 did not assist. There were rumours of funding difficulties during this time. In his oral evidence Dr Perry commented that the process 'could have been tighter'.<sup>544</sup> He thought that issues were considered and decisions taken by the ACVSB on an incremental basis. Long-term issues such as counselling and follow-up were not considered until the initial policy decision was taken to introduce screening.<sup>545</sup>

<sup>542</sup> Day 70, pages 50–51

<sup>543</sup> Day 68, pages 128–129

<sup>544</sup> Ibid, page 134

<sup>545</sup> Ibid, page 139

**31.379** Dr Perry thought the delay in mid-1991 was caused partially by attention being given to the introduction of the second generation test. As a result first generation kits were dismissed, whereas other countries had been content to introduce them.<sup>546</sup>

**31.380** Dr Perry said in his statement that ‘the actions of Newcastle Transfusion Centre ... whilst widely deprecated, were seen to potentially undermine the rigidity of a common UK starting date, or indeed the enforceability/validity of a “DOH policy”’.<sup>547</sup>

**31.381** Mr McIntosh recalled that he and Dr McClelland had, by May/June 1991, become concerned about the lack of progress regarding the implementation of testing. The SNBTS was able to introduce it, but was held back by waiting for the common UK start date.<sup>548</sup>

**31.382** The ACVSB held a meeting on 21 May 1991.<sup>549</sup> The Chairman referred (under ‘AOB’) to the existence of ‘the policy for a uniform starting date ... endorsed by all UK Health Ministers’ and noted that, despite Northern region’s action, ‘this policy remained firm’.<sup>550</sup> The policy appeared to have been firmed up. The trial of second generation kits had resulted in the decision that individual RTCs could decide themselves which test kit to use from Ortho 2, Abbott 2 or UBI.<sup>551</sup> Mr McIntosh made the point in oral evidence that, as the ACVSB met in confidence, he would not have been aware of the policy and it would not have affected his role in Scotland.<sup>552</sup>

**31.383** Dr Gunson presented details of the proposed extended trial to the ACVSB meeting.<sup>553</sup> This related to the extended trial of anti-HCV tests on blood donations which would now include data from the English, Northern region (Newcastle).

#### ***SNBTS Board meeting, Stirling, 11–12 June 1991 and its aftermath***

**31.384** The minutes of a two day SNBTS Management Board meeting in Stirling in June 1991 record, simply and rather tersely under the heading ‘Anti-HCV testing’, the words ‘Agreed – Routine donation testing to begin on 1<sup>st</sup> September 1991’.<sup>554</sup> Professor Cash agreed in oral evidence that the short note regarding HCV testing was not an accurate record of the discussion that led to the decision that was taken. He did not disagree that the discussion was essentially whether or not Scotland should announce ‘a UDI’ (‘unilateral declaration of independence’) which, in this context, meant Scotland introducing testing ahead of the rest of the UK, as had been done at Newcastle.<sup>555</sup>

**31.385** Dr McClelland composed a letter dated 11 June, addressed to Professor Cash, on the subject of anti-HCV testing.<sup>556</sup> He wanted the matter to be discussed at the Directors’ meeting and was concerned that the fact some centres were testing, albeit on a trial basis (in Newcastle and Glasgow), left the SNBTS very exposed. Dr McClelland wrote:

I would like to be reassured that we are taking the correct decision, both professionally and medical legally, to stay in line with the positions of the

<sup>555</sup> Day 82, page 152

<sup>556</sup> Dr McClelland’s letter [SNB.002.7902]

majority of English RHA's [Regional Health Authorities]; I think this is in fact what we are now doing rather than abiding by a Department of Health policy because it seems to me that de facto, [there] may no longer be a Department of Health policy in this area.

**31.386** It is not clear if Professor Cash received that letter in time for the board meeting of the same date.<sup>557</sup> The letter suggested, generally, that the issue of the introduction of screening should be discussed. Professor Cash agreed in oral evidence that it was an appropriate topic for discussion at the board meeting.<sup>558</sup> He recalled at one stage in his oral evidence that:

'[W]e [the SNBTS Board] initially got into a general debate with Brian [McClelland] ... responding to the points he was making in his letter ... it was either Brian or David McIntosh that made the move, that triggered off the sad deterioration in the meeting.'<sup>559</sup>

**31.387** Dr McClelland had no personal recollection of that meeting, or the discussion on anti-HCV screening. However, he provided the Inquiry with his own handwritten notes of the meeting,<sup>560</sup> and the section relating to anti-HCV screening was later transcribed by him at the behest of the Inquiry.<sup>561</sup>

**31.388** Dr McClelland recorded in his notes of the meeting that Professor Cash had stated at the meeting that: 'The UK pack is still a pack'.<sup>562</sup> Professor Cash commented in oral evidence that, he was 'reporting back that at that moment, with the exception of Newcastle, the position was being held'.<sup>563</sup> He added that at the time, 'the UK was operating, with the exception of our friends in Newcastle, as a single unit in respect of this topic'.<sup>564</sup>

**31.389** Dr McClelland had also recorded a further comment at the meeting: 'Can we make a strength of this by demonstrating that we have considered the early start option and rejected it in the interest of support/buttressing a coordinated national service'.<sup>565</sup> Professor Cash was unable to say whether that would have been a record of him speaking, but noted that it appeared on the same line as his initials.<sup>566</sup> Mr McIntosh agreed in oral evidence that it appeared to record the decision that was taken.<sup>567</sup>

**31.390** Dr Perry recalled in his statement that, despite Glasgow's involvement in the extended study from May 1991, 'SNBTS Directors remained supportive of a common UK start date, perhaps partly in the belief that SHHD would be unwilling or unable to countenance independent Scottish action'. He recalled further that:

[T]hese issues were considered and debated at some length at the SNBTS Board Meeting on 11<sup>th</sup>/12<sup>th</sup> June, although it was finally agreed to remain firm on the agreed date of 1st September 1991 ... as is very briefly recorded in the minute of that meeting.<sup>568</sup>

<sup>567</sup> Day 70, page 145

<sup>568</sup> Dr Perry's Statement [PEN.017.2108] at page 2117

**31.391** Dr Perry recalled that ‘very substantial discussion’ took place and that there were differing views at the Board meeting on the issue of the introduction of screening.<sup>569</sup>

**31.392** Mr McIntosh recalled that the Stirling meeting gave the SNBTS the opportunity to have a ‘serious discussion’.<sup>570</sup> He thought that in some ways it is ‘good practice’ after a ‘heated debate’ with a clear outcome and decision to simply record the decision.<sup>571</sup> In his statement to the Inquiry, Mr McIntosh set out his own memory of that debate, which he would have chaired. Funding was in place in Scotland, ministerial approval had been granted and operational matters ironed out.<sup>572</sup> Professor Cash recalled Mr McIntosh supporting Dr McClelland’s view at the Stirling meeting.<sup>573</sup>

**31.393** Mr McIntosh did not think Professor Urbaniak would have supported early implementation but he thought Dr William (Bill) Whitrow from Inverness and Dr Ewa Brookes in Dundee ‘shared concern’. Mr McIntosh also suggested that Dr Perry, although not a regional director, shared the concern of Mr McIntosh and Dr McClelland. He was doubtful that ‘sharing his concern’ amounted to a willingness to vote against the views of the medical director.<sup>574</sup> The views which Mr McIntosh expressed were described by him as ‘anecdotal and from distant memory’.<sup>575</sup> His views are disputed by some of those who attended the meeting and it is not now possible for the Inquiry to resolve the difference.

**31.394** There was no evidence, according to Mr McIntosh, that any civil servant had instructed the SNBTS to postpone until further notice the planned introduction of HCV testing on 1 April. The SNBTS was funded to introduce the test, not authorised to delay it.<sup>576</sup>

**31.395** On 17 June 1991 Professor Cash wrote again to Dr Gunson:

Picking up the pieces after last week’s near disaster up here.

Could you please:

1. Give me a date when all 2nd Generation Test Study data will be on your desk.
2. Give me the date when the Report (on the 2nd Generation Test Study) will be completed and the recommendations sent “to the Minister”.<sup>577</sup>

**31.396** The Inquiry probed the reference to ‘picking up the pieces after last week’s near disaster up here’. The majority of witnesses thought this referred to the Directors’ meeting of 11 and 12 June and the proposed early implementation of anti-HCV testing in Scotland. Mr McIntosh was adamant in oral evidence that Professor Cash was referring to his pride in having averted the disaster of Scotland going ahead, alone, to start screening for anti-HCV.<sup>578</sup>

<sup>574</sup> Day 70, pages 118–119. It has been pointed out to the Inquiry that the Directors did not formally vote at meetings.

<sup>575</sup> Day 70, page 118

<sup>576</sup> Ibid, pages 122–123

<sup>577</sup> Letter [SNB.011.8178]

<sup>578</sup> Day 70, page 57

**31.397** Professor Cash agreed in oral evidence that ‘last week’s near disaster’ was the prospect of the SNBTS going ahead with early screening, and ‘doing a Newcastle’.<sup>579</sup> If the SNBTS had gone ahead with screening at that stage, given the declared position of the Scottish Office, it would have been a breach of trust with them. He found this to be ‘unacceptable’.<sup>580</sup> He remarked in his statement that the Stirling meeting involved a hotly contested debate on the proposed early introduction of anti-HCV screening. The proposal was defeated, but if approved he feared ‘it could have triggered a descent into chaos’, with the risk of another potential ‘disaster’: the possible fragmentation of the UK BTS and the SNBTS.<sup>581</sup>

**31.398** The minutes of the June meeting were not approved until the 21 August Board meeting, when Mr McIntosh thought they must have been approved by everyone.<sup>582</sup> He could not recall, as suggested by Professor Cash, asking for the first draft of the minutes to be amended so that a report of the anti-HCV testing debate was removed from the record.<sup>583</sup> Mr McIntosh’s evidence on this point seems preferable given that the agenda for the Board meeting of 21 August – enclosing a revised copy of the draft minutes of the June meeting – stated that the draft minutes had been revised in light of comments by Professor Cash and others, but make no mention of Mr McIntosh having commented on or having sought to revise the draft minutes.<sup>584</sup>

### *Ministerial approval in Scotland*

**31.399** On 25 June 1991 Mr Hogg sent a note to Mr Panton asking, ‘can we discuss the submission format now...’.<sup>585</sup>

**31.400** On 1 July 1991 Dr McIntyre wrote to Dr Metters asking if the paper by Tedder et al in the *British Medical Journal*,<sup>586</sup> reporting ‘strong evidence for the sexual transmission of the Hepatitis C virus’, would pose problems for counselling donors found to be Hepatitis C positive and would, in turn, be ‘likely to result in any changes in the policy decision to implement routine screening on 1 September’.<sup>587</sup>

**31.401** On 11 July 1991 Dr Metters replied to Dr McIntyre’s letter of 1 July. The UKBTS Advisory Committee on Transfusion Transmitted Diseases was preparing advice for transfusion centres about counselling donors and would have regard to all of the latest information from the various studies. Dr Metters did not anticipate that advice from that Committee would influence the date of the introduction of routine hepatitis screening.<sup>588</sup>

**31.402** On a copy of Dr Metters’ letter, a handwritten note from Mr Panton to Mr Hogg dated 17 July 1991 stated: ‘We can now proceed with the Hep C submission. We must get it up this week before Recess’.<sup>589</sup>

<sup>579</sup> Day 82, page 113

<sup>587</sup> Dr McIntyre’s letter [SGH.002.7835]

<sup>588</sup> Letter [SGH.002.7834]

<sup>589</sup> Ibid [SGH.002.7834]

**31.403** It appears that the submission seeking approval for the introduction of routine testing of blood donations for anti-HCV did not go to Mr Forsyth (Minister of State with responsibility for health) until 24 July 1991.<sup>590</sup> This is in contrast to the submission for England and Wales, dated 21 December 1990.<sup>591</sup> Mr Tucker explained in oral evidence that the Scottish submission was delayed because it could not go to the Minister until a date for introduction had been set.<sup>592</sup> The submission would have been worked on by other civil servants before coming to Mr Tucker for a final check, prior to being forwarded to the Minister with the start date.<sup>593</sup> Mr Tucker thought approval in principle had already been given for testing, as the Minister did not object to its inclusion in the PES. The Minister turned the submission around in two days and was content to endorse the recommendation.

**31.404** The Scottish submission noted:

In anticipation that testing would be introduced in 1991/92 a PES bid was lodged and this was successful .... The costs for 1991/92 will be in the region of £700,000 and as indicated above this has been already included in the CSA allocation.<sup>594</sup>

**31.405** A draft press release was prepared which stated: 'The annual cost of the testing is in the region of £1.2 million and the Scottish National Blood Transfusion Service has been allocated additional funds to cover this'.<sup>595</sup> A copy of the submission, and a draft press release, were sent to the DoH by fax on 25 July.<sup>596</sup>

**31.406** On 26 July Mr Forsyth's Assistant Private Secretary replied to Mr Tucker to advise that the Minister agreed to endorse the recommendation that routine testing of blood donations for Hepatitis C antibody should be introduced in Scotland from 1 September 1991.<sup>597</sup>

**31.407** The press release was issued on 2 September, in almost identical terms as the original draft produced at the end of July.<sup>598</sup>

**31.408** Mr McIntosh was convinced when he gave oral evidence that the Minister must have had some awareness of the issue of screening as it was in the Public Expenditure Survey budget from April 1991 onwards.<sup>599</sup> He thought the Minister must have signed off on it for the money to have been authorised. He assumed the SNBTS budget would have been 'built' in the autumn of the year before.

### **Screening introduced in September 1991 – retrospective views of the process**

**31.409** On 8 August 1991 Mr Panton wrote to Mr Jim Donald at the Common Services Agency.<sup>600</sup> He stated: 'I am writing to formally advise you that the Minister of State has agreed to the routine testing of blood donations for the antibody to the Hepatitis C virus

<sup>598</sup> Final press release [SGH.002.7783]

<sup>599</sup> Day 70, pages 72-73

<sup>600</sup> Mr Panton's letter [SGH.002.7802]

(HCV) from 1 September 1991'. Funding was already in place and there were arrangements to be made that were necessary to allow testing to commence.

**31.410** On 12 August Professor Cash wrote to Mr Donald in response to his fax of 9 August.<sup>601</sup> The communication of 8 August from Mr Panton had triggered the final phase of a programme agreed at the SNBTS board meeting in June.

**31.411** On 29 August Professor Cash wrote to Mr McIntosh regarding the Stirling meeting and the SNBTS Board decision to stick to the uniform start date. He had recently read the minutes of the 21 May 1991 meeting of the ACVSB and noted the Chairman's comments that "the policy for a uniform starting date has been endorsed by all UK Health Ministers". Professor Cash went on to say in his letter, 'I think we made the right decision at our Board Meeting on 11/12 June 1991'.<sup>602</sup>

**31.412** Mr McIntosh replied by letter the very next day.<sup>603</sup> In it he communicated his conviction that they had taken the best decision available to them and expressed, with reference to the ACVSB minute, a degree of regret that such a record of clear UK policy had only come to his attention indirectly, through unofficial channels, and at such a juncture. He conveyed his belief that in the future, policy decisions potentially affecting the SNBTS should be conveyed to them, both formally and clearly, by the relevant authorities. He concluded his letter by noting that 'I remain convinced however that we can do a lot better next time than we managed, collectively (UK wide), to achieve over HCV'.<sup>604</sup>

**31.413** On 1 September 1991 the SNBTS (and the regional transfusion centres in England and Wales) finally introduced HCV screening of all blood donors using second generation ELISA and RIBA tests.

**31.414** Professor Cash responded to Mr McIntosh on 16 December 1991.<sup>605</sup> Professor Cash commented in oral evidence that the delay in replying was a result of him trying to think of what they could do about the situation.<sup>606</sup> By contrast, Mr McIntosh wrote back immediately on 17 December.<sup>607</sup> Professor Cash had noted in his letter that he was delighted with Mr McIntosh's response. Mr McIntosh commented in oral evidence that Professor Cash was 'being very supportive'.<sup>608</sup>

### Preparation of a history of events

**31.415** An ad hoc meeting was held at the National Directorate of the NBTS on 13 September 1991 to consider the implications of the introduction of anti-HCV testing.<sup>609</sup> The group comprised Dr Gunson, Professor Cash, Dr Mitchell and Professor Tedder. It was agreed that, in order to answer questions which might arise in the future with respect to the timing of the introduction of HCV antibody testing, the facts and decisions taken should be set out in chronological order. The minute of this meeting (revised on 5 February 1992) set out an account of Ortho's progress with their test systems, including their approaches to UK transfusion interests; Abbott's correspondence about their test; and the proceedings of the advisory committees.

<sup>601</sup> Letter [SNB.008.3956]

<sup>602</sup> Letter [SNB.002.0457] emphasis in original

<sup>603</sup> Letter [SNB.005.4822]

<sup>604</sup> Ibid [SNB.005.4822] at 4823

<sup>605</sup> Letter [SNB.014.0418]

<sup>606</sup> Day 82, page 132

<sup>607</sup> Letter [SNB.004.7207]

<sup>608</sup> Day 70, page 87

<sup>609</sup> Minutes of Meeting of UK Advisory Committee on Transfusion Transmitted Diseases [SNB.001.8919]

**31.416** This history of events may have been prepared in case, at a later date, questions were to arise as to whether there had been a delay in introducing HCV screening of blood donors in the UK. The minute did not refer to the following:

- The weight given to the lack of FDA approval of the Chiron/Ortho and anti-HCV ELISA test for use in the USA which was a factor down to 2 May 1990 when licensing of the test was announced (paragraph 31.209).
- The major concerns about funding in England and Wales that were explicit from at least 7 January 1991 (paragraph 31.258), underlined by Dr Pickles' memorandum of 5 February 1991 (paragraph 31.271) and which led to the DoH supporting Dr Gunson's suggestion of a start date of 1 July 1991.
- The ACTTD meeting of 25 March 1991 at which the difficulties in meeting the start date of 1 July were discussed (paragraph 31.330).
- The Newcastle initiative and its impact on the planned uniform start date.

### **Witnesses' views on the process**

**31.417** In an attempt to understand how more than two years passed between the launch of kits to test for the Hepatitis C virus and the introduction in the UK of screening of donated blood using such kits, the Inquiry included in the list of questions for witnesses a request for their individual opinions on the matter. The request was framed with reference to Mr McIntosh's letter of 30 August 1991 to Professor Cash.<sup>610</sup> This letter appeared to recognise that there had been failings in the process leading to the introduction of screening. In providing their statements, witnesses were asked to say whether they agreed with Mr McIntosh's views. Views which witnesses expressed in answering this question were then explored in oral evidence.

### **Dr Perry**

**31.418** As previously explained, Dr Perry was a member of the ACVSB. In the statement he provided to the Inquiry, he set out a considered response to the question seeking his views on possible failings in the process leading to the introduction of screening. His response was as follows:

My personal view is that the early decision to introduce new blood safety measures on a UK wide basis and on a common start date was correct. However I believe there were a number of shortcomings in the overall UK management process ultimately leading to a late delivery of that outcome. These included:

- Unnecessary secrecy and confidentiality associated with the considerations of ACVSB and other 'behind the scenes' discussions.
- Absent or confused processes for communication of ACVSB decisions to operational managers.
- A late recommendation in principle ... by ACVSB and DOH for the introduction of HCV testing. This appeared to be driven primarily by scientific rigour rather than urgent public health considerations.

---

<sup>610</sup> Letter [SNB.005.4822]. See discussion of this letter at paragraph 31.412

- The apparent absence of a clear plan, timescale, strategy or policy guidance (from either DOH or SHHD) for the introduction of testing following the decision in principle by ACVSB in July 1990 to introduce testing.
- The progressive (and largely unexplained) deferral of the UK start date from April to July to September 1991 believed to have been caused at least in part by administrative and funding issues between the English services and DOH rather than operational readiness.
- With hindsight, and given its readiness (both operational and financial) to introduce testing in early 1991, the failure of SNBTS to robustly argue a case for earlier introduction of testing in Scotland with SHHD/Scottish Ministers including the public health consequences of delays. Equally an SHHD apparent reluctance to consider such an option preferring instead to be guided exclusively by timescales determined by DOH.<sup>611</sup>

**31.419** In oral evidence, Dr Perry adhered to the views expressed in his statement. He also agreed that insofar as operational matters were being left to the ACTTD, the gap in meetings of that committee between March 1990 and January 1991 did not assist.<sup>612</sup> He described the period following the meeting of the ACVSB in November 1990 as ‘particularly confused’.<sup>613</sup> In relation to the implementation of a decision to introduce screening, it would have helped if there had been ‘scenario planning’, addressing in advance what practical steps would be required should a decision be taken to introduce screening.<sup>614</sup> Part of the reason for the lack of such planning was the limited communication of the deliberations of the ACVSB. This was due both to the insistence on confidentiality and to there being no structured approach to communication by the officials who attended the meetings; these officials were there to communicate back to operational bodies such as the SNBTS matters which were important for planning and policy purposes, but such communication appeared to Dr Perry to have happened only on a sporadic basis.<sup>615</sup>

**31.420** In relation to the composition of the ACVSB, Dr Perry’s view was that the membership could have been more broadly based.<sup>616</sup> By that he meant that there could have been people, ‘with a slightly greater public health perspective on it’,<sup>617</sup> although he did pay tribute to Dr Mortimer, who was an expert virologist who brought a useful public health perspective to discussions.<sup>618</sup> Dr Perry observed that this was not a process failure, as the membership was determined at the outset of the process.<sup>619</sup> In this regard, however, the Inquiry notes that the membership did change during the period 1989 to 1991 and an additional member or members with a public health background could have been added.

<sup>617</sup> Ibid, page 137

<sup>618</sup> Ibid, page 13

<sup>619</sup> Ibid, page 144

## Dr McClelland

**31.421** Dr McClelland had noted in his statement that he agreed there were ‘failings in the process’ leading to the introduction of HCV screening<sup>620</sup> and expanded on this during his oral evidence. In his view, ‘something about the nature and the functioning of the institutions concerned in the UK, was profoundly different [from other countries] and led it to actually being one of the last countries to institute Hepatitis C testing’.<sup>621</sup>

**31.422** In focusing on the implications of the policy for a common UK start date, Dr McClelland observed that those involved in trying to implement screening ‘should have been much more open to recognising that there were problems in certain parts of the country and looked for a way of managing a phased introduction’.<sup>622</sup> He considered that the perception that non-A non-B Hepatitis was a US problem was relevant to the perceived ‘lack of urgency’.<sup>623</sup> The composition and chairmanship of the committee was also relevant. The focus was ‘very virological, very transfusion process-orientated and there wasn’t a loud enough voice ... saying: what about the patients?’.<sup>624</sup>

**31.423** Dr McClelland suggested that the SNBTS could have worked harder on ‘influencing, through Scottish Home and Health Department, civil servants and medical officers... through influencing them, influencing the Minister to make a decision that on this issue Scotland needed to get on with it and go it alone’.<sup>625</sup>

## Mr McIntosh

**31.424** In providing his views to the Inquiry, Mr McIntosh drew a distinction between his impression at the time, according to his recollection in 2011, and opinions he had formed in hindsight. He concentrated on the period after 21 November 1990, when the ACVSB had agreed at its meeting that the UK should introduce Hepatitis C screening of blood donations as soon as practicable.<sup>626</sup>

**31.425** In Mr McIntosh’s view, the policy at the beginning of 1991 was that there should be coordination between Scotland, on the one hand, and England and Wales on the other, and that the start date for screening should be 1 April 1991 across the UK.<sup>627</sup> Funding was in place for screening in Scotland; the target date of 1 April 1991 was, and remains in hindsight, ‘a highly appropriate date for full implementation throughout Scotland’.<sup>628</sup> Had a comprehensive brief been sent to the SHHD in May 1991 and had the up-to-date position and consequences been explained to Ministers, they ‘would surely have decided to authorise the immediate introduction of testing throughout Scotland’.<sup>629</sup> Instead the revised SNBTS position was not put to the SHHD or Ministers until the end of July 1991,<sup>630</sup> at which point the SHHD formally asked Ministers to endorse the commencement of testing on 1 September 1991. The timing of the submission to Ministers in Scotland made it clear that the department ‘was not leading but following’.<sup>631</sup> The most important reason

<sup>620</sup> Dr McClelland’s Statement [PEN.017.2491] at 2503

<sup>625</sup> Day 69, page 76

<sup>626</sup> Meeting Minutes [SNF.001.1777]

<sup>627</sup> Statement [PEN.017.2126] at 2139 paragraph 7.4. No date is recorded in minutes of ACVSB meeting of 21 November 1990

<sup>628</sup> *Ibid* [PEN.017.2126] at 2140 paragraph 7.8

<sup>629</sup> *Ibid* [PEN.017.2126] at 2140 paragraph 7.10

<sup>630</sup> Although Mr McIntosh had thought that the submission was not sent till August, he accepted that it was sent at the end of July 1991. Day 70, page 91

<sup>631</sup> Statement [PEN.017.2126] at 2144, paragraph 7.15

that Ministers in Scotland did not grant approval for the implementation of testing in the first six months of 1991 was that they were not asked or advised to do so.<sup>632</sup>

**31.426** In Mr McIntosh's opinion, it should have become clear from the first quarter of 1991 that an unsatisfactory outcome was on the cards; more should have been done to have policies and a strategy properly determined and committed to paper, with ministerial approval in place before the end of March 1991.<sup>633</sup> If there had been a formal departmental brief issued at the beginning of 1991, the SNBTS could have been working towards implementation in Scotland in April or perhaps May 1991. Mr McIntosh made the point that different starting dates between Scotland and England/Wales would not have meant a lack of coordination and cooperation.<sup>634</sup> In the absence of an instruction from the SHHD, there should have been, in Mr McIntosh's view, a strategy document from the SNBTS to set out for the CSA, for the SHHD and for Ministers 'the shape and size ... of the problem'.<sup>635</sup> He set out an example of what such a memorandum might have said.<sup>636</sup>

**31.427** What occurred in practice however was that all guidance was coming to the SNBTS via second-hand reporting of advice, recommendations and pronouncements from bodies not part of the SNBTS chain of command. The roles and authority of the ACVSB and the ACTTD over the SNBTS were not clear.<sup>637</sup>

**31.428** Mr McIntosh saw as the key lesson that:

When faced with an ambiguous policy background and a lack of clear leadership from above on an issue as important as this one was, the Service itself must take the lead, on its own responsibility and focusing firmly on its key patient care responsibilities.<sup>638</sup>

### Professor Cash

**31.429** In his statement, Professor Cash told the Inquiry that he agreed with Mr McIntosh's view that there had been failings in the process, and added that he thought there had been 'a good deal more than failings!'.<sup>639</sup> In elaborating this answer in oral evidence, Professor Cash referred to the difficulty for the SNBTS in having input to the meetings of the ACVSB.<sup>640</sup> There were also, he thought, failures of communication and of transparency.<sup>641</sup>

**31.430** Professor Cash also expressed the view that, had an approach been made to the SHHD in the summer of 1991 to propose the introduction of screening in Scotland ahead of the rest of the UK, it would not have been successful.<sup>642</sup>

## Discussion

**31.431** In closing submissions, Counsel to the Inquiry advanced eight questions in this area.<sup>643</sup> They were:

1. When it became apparent in 1988 that tests for the hepatitis C virus were shortly to become available, was there a satisfactory mechanism for determining whether these tests should be introduced for the screening of donated blood in Scotland?
2. When it became apparent that the introduction of screening for hepatitis C might be recommended, was there a satisfactory mechanism for determining when and how the introduction of screening in Scotland would be effected?
3. Whether the existence of two groups with similar remits (the ACVSB and the ACTTD) impeded decision-making.
4. The factors which contributed to there being no decision until November 1990 to recommend to Ministers that screening should start as soon as practicable until November 1990.
5. Why was there a delay of almost ten months between the decision by the ACVSB on 21 November 1990 to recommend the introduction of screening as soon as practicable and the introduction of screening in Scotland on 1 September 1991?
6. Whether, during this period, the involvement of the Health Minister earlier than July 1991 would have led to earlier introduction of screening.
7. The formulation of policy regarding the coordination of the start date for the introduction of screening in Scotland, with the start date for England and Wales, the flexibility of such policy and whether such policy as existed resulted in delay in the introduction of screening in Scotland.
8. The relevance to the decision-making process of the Consumer Protection Act 1987, and the relevance for the consideration of this Inquiry of the decision in *A v National Blood Authority* [2001] 3 All E R 289.<sup>644</sup>

The last question raises matters of law. It is convenient to address it first.

**31.432** In the litigation referred to in question 8, 114 claimants who were infected with the Hepatitis C virus from treatment with blood or blood products raised proceedings under the Consumer Protection Act 1987. These claimants were all infected after 1 March 1988, the date when the provisions of the Act came into effect, but before screening was introduced in 1991. The defendants were the National Blood Authority and others, essentially all those who were, or had become, responsible for the production and supply of blood and blood products in England and Wales. During the course of the litigation, it was agreed that the claims of those infected after 1 April 1991 would no longer be opposed (on the basis that these claimants would receive 90% of the damages to which they were entitled). Thus, the judgement does not scrutinise in detail the course of events after that date.

---

<sup>643</sup> Closing submission – list of issues – Inquiry Counsel [PEN.019.0843] at 0855

<sup>644</sup> A copy of the judgment is at [PEN.017.0302]

**31.433** When before that date testing of donated blood should have been introduced in England and Wales was considered by Burton J in great detail, based on an analysis of the factual and legal position, almost all of which involved examination of the same events as were discussed before the Inquiry. There were arguments in relation to surrogate testing, which was never introduced, and in relation to the delay in starting to test all donated blood for antibodies to the virus.<sup>645</sup> To a minor extent, some evidence emerged at the hearings of the Inquiry which was not before Burton J and, of course, he did not consider any circumstances specific to Scotland.

**31.434** This exercise – that is, determining questions of liability under the Consumer Protection Act 1987 for the non-introduction of Hepatitis C testing, – did not involve the law of negligence, but a matter of statutory liability, based on underlying European legislation. As Burton J expressed it:

What is to be done is, as against what did occur, to set out what I may be persuaded should have occurred, in the round. This involves my looking realistically as to how much time it is legitimately to be expected that the producer should have taken to introduce the precaution which he did rightly introduce but, as the Claimants allege, later than he ought to have done had he taken all legitimately expectable steps.<sup>646</sup>

**31.435** In the part of his judgement dealing with the delay in introducing what Burton J refers to as ‘the assay’, a table is set out to illustrate the position in the 25 countries referred to by the parties to the case.<sup>647</sup> These countries are in Europe, with the addition of the USA, Canada, Australia and Japan. The table shows that of those 25 countries, the last two to introduce screening for Hepatitis C were the UK and Ireland, in September and October 1991. Burton J concluded that the basic requirements which had to be satisfied before screening could be introduced were the carrying out of pilot studies and evaluations, the planning for counselling and implementation and the execution of that implementation in respect of equipment, staff and building works. In light of his assessment of how long these steps should have taken, he concluded that, as a matter of fact, routine screening ought to have been introduced by 1 March 1990.<sup>648</sup>

**31.436** This Inquiry is not bound by the decision of Burton J. It was reached in a different jurisdiction and it addressed a different question, namely that of legal liability to a group of claimants. But, as already observed, the case involved examination of the same factual material as did the investigation of this topic by the Inquiry. The decision (that after 1 March 1988, by which time surrogate testing should have been in place, blood and blood products infected with the Hepatitis C virus did not provide the safety which persons generally were entitled to expect) was not appealed. Before the Inquiry, there was no attempt to argue that the delay in introducing anti-HCV screening until September 1991 was justified, or even reasonable. The Inquiry has therefore started from the proposition that there was unjustified delay in introducing screening, and has tried to analyse how it occurred.

---

<sup>645</sup> Issues relating to surrogate testing are considered in Chapter 27, *Surrogate Testing of Donated Blood for non-A, non-B Hepatitis*

<sup>646</sup> Judgement [PEN.017.0302] at 0388, paragraph 145

<sup>647</sup> Ibid [PEN.017.0302] at 0387, paragraph 143

<sup>648</sup> Ibid [PEN.017.0302] at 0405, paragraph 172 ii)

**31.437** The issues which are highlighted in the remaining questions set out above at paragraph 31.431 are all relevant to the task of trying to identify the factors which led to the delay. These issues are addressed in the discussion which follows. It is appropriate to comment first on the two main advisory bodies, the ACVSB and the ACTTD.

### **The ACVSB and the ACTTD**

#### *Was a new body required?*

**31.438** When it became apparent in 1988 that tests for the Hepatitis C virus were shortly to become available, there was no satisfactory mechanism for determining whether these tests should be introduced for the screening of donated blood in the UK as a whole, and in Scotland in particular.

**31.439** To some extent the constitutions of the two committees that emerged reflected two distinct needs. The constitution of the ACVSB had to meet a need for scientific expertise. The main qualities required of its members would relate to the range of relevant real expertise and acknowledged authority drawn upon. Geographical representation might be uneven. In particular, office holders in territorial BTS organisations would not have been considered for selection in that capacity. Such advisory committees frequently, if not invariably, operate on a UK-wide basis, drawing on expertise from all parts of the UK where that is possible. In contrast, the ACTTD had a more practical focus and had to reflect practices in the constituent parts of the service as a whole. It would be expected that there would be representation of the territorial organisations.

**31.440** The ACTTD could not, at its own hand, establish the relationships necessary to ensure the level of collaboration that would have been required to provide fully informed advice to government, taking account of science and the practical transfusion issues that would emerge. As already commented; unfortunately, the terms of reference adopted by the ACTTD at its first meeting cut across the remit of the ACVSB.<sup>649</sup> The qualification to the ACVSB terms of reference, which was adopted on 4 April 1989, appeared to subject all changes in transfusion practices that would have major implications for other related bodies, to the ACVSB for prior oversight.

**31.441** As a practical matter, the potential for discord was real in Scotland, but it appears that it did not have practical effect in England and Wales. Dr Gunson, National Director of the NBTS in England and Wales, was a member of the ACVSB and of the ACTTD, and was in direct contact with the DoH. He also coordinated the work of Regional Transfusion Directors in England in instructing tests on behalf of the ACVSB. In contrast, Professor Cash, National Medical and Scientific Director of the SNBTS and Dr Gunson's equivalent in Scotland, was not a member of the ACVSB. Further, the policy of confidentiality pursued meant that Professor Cash was not fully informed of the thinking of the ACVSB, even when it dealt with transfusion issues relating or potentially relating to Scotland.

**31.442** In 1988, the UK Government did not have in place suitable advisory bodies to deal with emerging knowledge of HCV as the means of addressing the risk of infection with the disease in the course of NHS treatment and management. That was the view of Dr Gunson, Dr McClelland and Dr Pickles in the early part of the year. It was also the view of Dr Harris when he addressed the issue in July 1988. His opinion may have involved a particularly narrow view of the skill sets of the members of the EAGA in the context of

---

<sup>649</sup> See paragraph 31.44

transfusion medicine. Professor Cash and Dr McClelland especially thought that the EAGA might explore infection-related matters other than AIDS.<sup>650</sup> Even their view, however, serves to emphasise the lack of an appropriate vehicle for the provision of advice on viral diseases more widely. In the context envisaged by Dr Harris, the view that a new body was required was clearly correct. In principle, the need for a new advisory body was never challenged once it had been articulated by him. Professor Cash's response to the proposal, in July 1988, was to welcome the establishment of a UK group and to comment that he would appreciate, in due course, the opportunity to provide an input with regard to its membership.<sup>651</sup>

**31.443** While departmental responsibility for implementing government policy in relation to health was allocated to the Secretary of State for Scotland, it would not have been an appropriate use of resources to equip the Scottish Office generally, and the Scottish Home and Health Department in particular, with all of the skills required, first to assimilate the advice of advisory and other external bodies and then to advise Scottish Office Ministers independently of the advice available to their colleagues in United Kingdom Departments. The team of Scottish Office officials, medical and administrative, was small, and could not have been expected to act without reference to counterpart teams in the DoH. So far as obtaining advice to inform policy decisions is concerned – ultimately a facet of Cabinet government, collaboration and joint consultation – recognising the superior resources of the DoH is not open to criticism.

**31.444** It appears that to avoid budgetary issues and to avoid referring the proposals to Ministers, Dr Harris originally envisaged that the new group would be a working group of the existing NBTS Advisory Committee. What emerged was a properly constituted Advisory Committee, appointed by Ministers to advise Ministers.

**31.445** The evidence does not disclose the process by which the change was brought about nor why so much time passed between the new committee first being proposed by Dr Harris in July 1988<sup>652</sup> and the first meeting of the ACVSB on 4 April 1989. No explanation has been found for the time taken in bringing forward the proposal for Ministers' approval.

**31.446** The ACVSB interpreted its remit as relating to matters of major policy. That was reinforced by the committee at its meeting on 24 April 1990. As established, the ACVSB conformed to a well-understood model of an advisory committee, providing government with advice related to policy issues which would in turn be resolved by Ministers. Typically, it was composed of a small core of experts with relevant specialist knowledge and experience, and was attended by representatives of the government departments as observers. It was chaired by the Deputy Chief Medical Officer for England.

**31.447** In practical terms, that was reflected in Dr Perry's evidence. He said that the ACVSB was established by UK Ministers to provide expert advice and ensure a uniform approach on blood safety throughout the UK.<sup>653</sup> The group was considered to be the authoritative source of advice for Health Departments and Ministers.<sup>654</sup> Representatives of the Health Departments from Scotland, Wales and Northern Ireland attended meetings as observers.<sup>655</sup>

<sup>650</sup> See paragraph 31.47

<sup>654</sup> Ibid [PEN.017.2108] at 2109

<sup>655</sup> Ibid [PEN.017.2108] at 2113

**31.448** There is no reason to doubt that the ACVSB was set up to fill a gap in the advice available to the UK Health Departments on measures required to ensure the virological safety of blood. It has to be noted that a factor contributing to the lack of expert advice on NANB Hepatitis was the premature disbandment of the MRC Working Party on Post Transfusion Hepatitis (of which Dr McClelland was a member) following its second meeting on 25 June 1981.<sup>656</sup> For a time, the EAGA masked the gap, certainly whilst AIDS was the more pressing problem. There had been a lack of structure in the arrangements for ensuring that the government had properly informed advice in making policy decisions. Establishment of a committee dedicated to consideration of the risk of transmission of viruses by blood and blood products was objectively required.

**31.449** The origins of the ACTTD were significantly different. It was not a government sponsored committee. It probably arose from an initiative of Dr Gunson, agreed by SNBTS Directors on 13 December 1988, to form a UK blood transfusion services group on microbiological testing.

**31.450** From the outset, Dr McIntyre appears to have seen the establishment of a committee by the Transfusion Directors as a negative development. In his letter of 9 January 1989 to Dr Pickles, he indicated that the Directors' proposals for a committee would be unsatisfactory since 'decisions reached might be influenced to a considerable extent by the views of the Transfusion Directors'. It is not easy to understand what Dr McIntyre meant in expressing his concern that the SHHD might be 'forced into a course of action which might have repercussions for the UK as a whole', though it did emphasise his view that the ACTTD would be a threat to the SHHD and the DoH.<sup>657</sup>

**31.451** Dr Perry had no direct knowledge of the evolution of the two separate groups, but his understanding was that:

[T]he ACTTD was established by the UK Transfusion Services, in the absence of any other suitable mechanism at the time, to coordinate its professional view on the need for additional measures concerning the virological safety of blood and any ... new or revised safety interventions. The original intention ... was that it would provide advice to the Departments of Health either on request or at its own instigation.<sup>658</sup>

**31.452** He commented further in oral evidence that:

[T]ransfusion directors in the UK felt that it would be better if there was a formal process or a committee that could primarily bring together all the expert views on various subjects, but also expecting there to be quite serious and important discussions around surrogate testing.<sup>659</sup>

### *The committees' roles in practice*

**31.453** Hindsight suggests that some of the difficulties that arose between the two committees might have been avoided had the ACVSB been established with a sub-committee, consisting mainly of members with transfusion experience, addressing implementation of policy. Due to their different origins, the terms of reference adopted by the ACTTD at its first meeting on 24 February 1989 cut across the concerns of the

---

<sup>657</sup> Letter [SGH.003.1251]

<sup>658</sup> Dr Perry's Statement [PEN.017.2108]

<sup>659</sup> Day 68, page 4

ACVSB as they were to emerge. In specifying a role in advising the Departments of Health on policy to be implemented by the UK blood transfusion services for the control of transfusion-transmitted diseases, the terms of reference had the potential to give rise to demarcation disputes. At the first meeting of the ACVSB on 4 April 1989,<sup>660</sup> the role of the ACTTD was interpreted as covering many of the same issues as the ACVSB, 'but only from a transfusion standpoint', a qualification that in itself had considerable potential for dispute. The second branch of the ACVSB remit was closely related to the operation of the Blood Transfusion Services, and the remit could not be fulfilled without knowledge of the practical implications of advice on scientific matters.

**31.454** The respective roles of the two bodies were specifically addressed at the meeting of the ACVSB on 24 April 1990.<sup>661</sup> As discussed below, while Dr Metters emphasised at that meeting that the ACVSB was concerned with policy and the ACTTD was concerned with operational matters arising from the implementation of policy, the ACVSB does not appear to have always borne that distinction in mind in their deliberations. Dr Gunson's view that there was no conflict between the committees was over-optimistic.

**31.455** Dr Perry commented that the ACVSB could not have functioned 'without the ACTTD, without creating an operational group to explore some of the details that it needed to make its decisions'.<sup>662</sup> From his perspective as a member of the ACVSB, and his knowledge of the workings of the ACTTD, Dr Perry suggested that the ACTTD was more 'action centred' and was more likely to generate work from its meetings. By contrast, if the ACVSB required additional work to be done, it would, in his view commission that through Dr Gunson and the ACTTD.<sup>663</sup>

**31.456** Dr Perry added that the ACTTD brought a 'collegiate expert view from transfusion experts ... with a view ... to advis[ing] departments of health on issues that they thought the Department of Health should be acting on'.<sup>664</sup> The ACTTD provided Dr Gunson with expert views to transmit to the Department of Health. Dr Gunson was the National Director of the Blood Transfusion Service in England and Wales, and in addition Dr Perry thought Dr Gunson was the expert adviser to the Department of Health.<sup>665</sup>

**31.457** Dr McClelland, who generally had a clear insight into the functioning of the transfusion service, said that it was never clear to him why it was necessary to have two committees. He suspected two groups eventuated because both the DoH and Dr Gunson, the NBTS National Director, wanted to influence decision making.<sup>666</sup> However, Dr McClelland commented that it was consistent with the remit of the ACVSB to 'cover all the territories' and include observers or participants from the other health departments.<sup>667</sup>

**31.458** Professor Cash commented in his statement that he thought the ACTTD was the 'brain-child' of Dr Gunson who believed it would help him to take the views of a wide group of UK BTS experts to the ACVSB.<sup>668</sup> Professor Cash commented that Dr Gunson was at times in a difficult position when he thought advice generated by the ACTTD would not be acceptable to the Department of Health.<sup>669</sup>

<sup>663</sup> Ibid, page 22

<sup>664</sup> Ibid, page 4

<sup>665</sup> Ibid, page 5

<sup>666</sup> Dr McClelland's Statement [PEN.017.2491]

<sup>667</sup> Day 69, page 2

<sup>668</sup> Professor Cash's Statement [PEN.017.2094] at 2095

<sup>669</sup> Ibid [PEN.017.2094] at 2095

**31.459** Mr McIntosh commented in oral evidence that it would be too simplistic to classify the ACVSB as dealing with ‘policy’, and the ACTTD as dealing with ‘operations’.<sup>670</sup> In reality he thought there was some overlap in their work, and there were tensions and some unhappiness between the two committees.

**31.460** The ACVSB did not, however, restrict its work to providing independent expert advice to government to assist in formulating policy. It discussed, and took decisions on, operational matters that impacted on the transfusion services. Specific examples have been highlighted in the narrative of the evidence, in particular the instruction of the three-centre comparative trial of the first generation Abbott and Ortho tests, in which the ACVSB appears clearly to have been entering into the ‘operational implications of policy’ (the function of the ACTTD).<sup>671</sup> The committee also took account of the implications of funding in its deliberations, instructed by Dr Metters and influenced by Dr Gunson. Dr Metters’ understanding of UK Government policy, that there would be no new money for screening and that health boards (at least in England and Wales) would have to find the necessary funds within their existing budgets, was an important consideration for government. But it is not obvious that it should have been a consideration for the experts on the ACVSB. One would have expected them to give independent, objective and scientific advice, and to have left it to the health departments to weigh that advice against its financial implications in the broader context of health policy.

### *Locus of ACVSB in Scotland*

**31.461** In the view of Mr Tucker, the SHHD was content to leave the ACVSB to assess whether introducing screening was the right thing to do: it was an expert committee. The SHHD would get a report-back of ACVSB meetings from their observer, Dr McIntyre.<sup>672</sup> Mr Tucker had been given the opportunity of examining the relevant SHHD file from the time in question and noted that the Minister of State, Mr Forsyth, appeared to be content for action to be taken in Scotland in line with England. He thought all Ministers at that time were part of the same government and would have no desire to break ranks and embarrass other colleagues by taking contradictory action without due cause.<sup>673</sup> They would want to present a ‘united government on an issue like this’.<sup>674</sup>

**31.462** In the opinion of Mr Tucker, as expressed in his statement, it was not unusual for the SHHD to follow the DoH lead on national issues if it was sensible to do so, as the Department of Health had greater resources. He felt that the introduction of national testing was a good example, as it was clear from the expert advice of the ACVSB that bringing in screening was the right thing to do and there was no disagreement in the committee. He said that the SHHD would not necessarily have followed the DoH if England had decided not to introduce screening, but the advice in Scotland had been that testing was worthwhile.<sup>675</sup>

**31.463** This perception within the SHHD that matters could be left in the hands of the DoH, as advised by the ACVSB, implied that the SHHD was not itself required to promote discussion or investigation of an issue such as the introduction of screening, and could

<sup>674</sup> Day 69, page 107

<sup>675</sup> Mr Tucker’s Statement [PEN.017.2060] at 2063

await advice from England, with a degree of assurance that it would have the backing of a ministerial decision that the Health Services should stay in line. The SHHD had the advantage, meantime, of information from its observer of the proceedings at the ACVSB, Dr McIntyre. He produced a note of the first ACVSB meeting, which was discussed with Dr Perry in oral evidence.<sup>676</sup> It was understood that, as an observer, Dr McIntyre could formally provide information from the Department of Health to colleagues in the SHHD. The transfusion services did not have the advantage of direct reporting other than through Dr Mitchell and Dr Perry, but relied on the information being further passed to them by the SHHD.

**31.464** Mr McIntosh also said that no-one involved in the management of the SNBTS felt that the ACVSB had any locus in Scotland. The activities of the Advisory Committee in London did not have any effect on his role as general manager of the SNBTS.<sup>677</sup> He remarked later that the SNBTS had a duty to formulate policy for itself and take it forward, rather than relying on bodies like the ACVSB and the ACTTD with no executive or medico-legal responsibility for the activities of the SNBTS in Scotland.<sup>678</sup>

#### *Confidentiality of the proceedings of the ACVSB*

**31.465** Having regard to the whole of the evidence as it developed, it appeared that the most substantial cause of dissatisfaction in Scotland with the ACVSB was not that its role was opaque or difficult to understand. It was that its business was confidential and was not reported in detail to the SNBTS or to the ACTTD. Due to the requirement of confidentiality, as perceived by its Scottish members, the SNBTS general manager and its Medical and Scientific Director were not always informed of the content of debates or decisions at the ACVSB meetings.

**31.466** At the first meeting of the ACVSB, the position was made clear by Dr Harris. Members' advice could be publicly sensitive and should not be discussed outside the committee, unless specifically authorised.<sup>679</sup>

**31.467** The perception, therefore, was that confidentiality had to be maintained. Dr Perry told the Inquiry that it was not appropriate for him or Dr Mitchell to return from the committee and brief SNBTS colleagues on the activities of the committee as they were prevented from doing so by confidentiality agreements.<sup>680</sup>

**31.468** Dr McIntyre could formally provide information from the Department of Health to colleagues in the SHHD: the SHHD was among the bodies entitled to receive the advice of the ACVSB. The SHHD could pass information to the SNBTS when it was necessary for individuals to be briefed.<sup>681</sup> Dr Perry believed that Dr McIntyre was able to relay information to his own department in Scotland, provided that information remained within the Government.<sup>682</sup>

<sup>676</sup> Note of Meeting of the Advisory Committee on the Virological Safety of Blood, 4 April 1989 [SGH.003.1228] and Day 68, pages 17–18

<sup>677</sup> Day 70, page 11

<sup>678</sup> Ibid, page 86

<sup>679</sup> Paragraph 31.51

<sup>680</sup> Day 68, page 18

<sup>681</sup> Ibid, page 18

<sup>682</sup> Ibid, page 21

**31.469** As already noted, at its inception, the ACVSB conformed to a well-understood model of an advisory committee providing government with advice related to policy issues. Confidentiality of its proceedings reflected that. Information that Ministers were entitled to accept or reject in formulating policy, in relation to which technical information was one only among a wide range of possible considerations, was inherently sensitive.

**31.470** It followed that, as Dr Perry recognised, he and Dr Mitchell were unable to brief colleagues in the SNBTS about ACVSB business.<sup>683</sup> It followed also, that SNBTS Directors would not have a role in suggesting items for the agenda of the ACVSB, and could not submit briefing papers or have access to minutes of the meetings. Professor Cash's comment to that effect reflected the formal reality of the status of the ACVSB, though he saw it as a deficiency in the arrangements.<sup>684</sup>

**31.471** Dr Perry's view was that the issue of confidentiality was a difficulty for the SNBTS, as policy discussed at the ACVSB often became operational practice and there was concern the SNBTS might be left behind.<sup>685</sup> He commented that there was '[u]nnecessary secrecy and confidentiality associated with the considerations of the ACVSB and other 'behind the scenes' discussions'.<sup>686</sup>

**31.472** With Dr Perry and Dr Mitchell bound by an obligation of confidentiality and the SNBTS general manager and its Medical and Scientific Director otherwise dependent on the SHHD as an additional source of information, there was some dissatisfaction within the SNBTS about the extent of the information coming from the ACVSB. This was remedied, to some degree, in February 1990 when it was confirmed by Mr Rab Panton of the SHHD that Drs Mitchell and Perry could report the committee's discussions and recommendations to the SNBTS Directors and the ACVSB minutes could be scrutinised and discussed, on an informal basis, at the directors' meetings.

**31.473** Professor Cash, as Medical and Scientific Director, remained dissatisfied with the provision of information. He considered it to be patchy and inconsistent. He commented that Dr McIntyre, as the SHHD observer on the ACVSB, told him that he would advise him when he believed there were things he, Professor Cash, should know. He complained about lack of regular briefings and said that the SNBTS Directors got to see the ACVSB minutes only on 'rare occasions'.

## **How the policy decision on screening was reached – a chronological review**

### **1989**

**31.474** From the starting point of the UK Ministers' decision on a uniform start date for the introduction of screening, all relevant agencies subscribed to the view that UK blood transfusion services should act in unison. Dr Perry thought it was the accepted view of the ACVSB that testing would be implemented in a coordinated manner across the UK. Professor Cash strongly supported the idea of a common start date.

**31.475** In the course of 1989, the NBTS and the SNBTS proceeded with the evaluation of test kits received from Ortho. By the end of August 1989, UK commentators appear to have formed a generally favourable view of the first generation Ortho test. There were still

---

<sup>683</sup> Ibid, page 18

<sup>684</sup> Professor Cash's Statement [PEN.017.2094]

<sup>685</sup> Day 68, page 19

<sup>686</sup> Dr Perry's Statement [PEN.017.2108] at 2118

reservations related, for example, to the predictive value of the test in low HCV prevalence populations, such as UK blood donors. Several commentators thought that without a confirmatory test, using an antibody distinct from that used in the initial screening test, there would be serious problems for the blood transfusion services in differentiating between true and false positives. The issues around the specificity and sensitivity of the first generation Ortho HCV ELISA test could not be addressed definitively as part of the evaluations carried out. There were no samples with well established links to NANB Hepatitis available to be tested.

**31.476** In September 1989, Dr Gunson and Dr Mitchell had acquired better knowledge of the international scene from the Rome symposium organised by Ortho. In their respective reports for the ACTTD, each expressed concerns about the lack of a confirmatory test.

**31.477** At the end of his report,<sup>687</sup> Dr Gunson asked the ACTTD to approve in principle the routine testing of blood donations for anti-HCV, and to request the National Directors in England and Scotland to arrange for the simultaneous introduction of the tests at an appropriate time when a policy for handling the seropositive donors had been defined. Dr Gunson's report was amended for submission to the fourth meeting of the ACVSB on 6 November 1989.<sup>688</sup> So far as procedure is concerned, the ACVSB had asked for advice and the ACTTD had approved a report for submission. The ACVSB was asked to approve routine testing for anti-HCV in principle, subject to conditions relating to counselling and management, the availability of a confirmatory test, an FDA licence, and pilot studies of routine use of the test on freshly collected blood.

**31.478** At this stage, the blood transfusion services, through the ACTTD, had played their part in recommending the introduction of routine screening in principle. The initiative now lay squarely with the ACVSB. On 6 November 1989, the ACVSB stopped short of approving the introduction of routine testing, in principle or otherwise.<sup>689</sup> It was decided that three English centres should conduct pilot studies of the feasibility of adding the kits to routine practice. There was no firm intention to recommend screening once the conditions outlined in Dr Gunson's report had been met. The ACVSB appeared unwilling to go further than to offer support for 'general introduction' if the three conditions were met. At this point, that position was not open to objection. The conditions were substantial, and hesitation in recommending positive action was understandable.

## 1990

**31.479** By the time the ACVSB next met, on 17 January 1990,<sup>690</sup> the FDA had licensed the Ortho product for export,<sup>691</sup> and the pilot studies had been completed, showing satisfactory test sensitivity and specificity. The emphasis changed. Discussion became more specific in relation to FDA approval for domestic use. The committee had a letter from Professor Zuckerman pointing out that 'considering the overall morbidity of chronic non-A non-B hepatitis ... and litigation which would be indefensible, the introduction of screening could not be delayed much beyond FDA approval'.<sup>692</sup> So far as the minutes disclose, there was no clear recommendation in favour of testing, even once any remaining

<sup>689</sup> ACVSB Minutes [SNB.001.9563]

<sup>690</sup> ACVSB Minutes [SNB.001.9657]

<sup>691</sup> Professor Cash was so informed by Ortho on 27 November 1989, see [SNB.006.1560]. Dr Gunson was informed at the same time – see [SNB.001.8919]. The information does not appear to have reached ACVSB.

<sup>692</sup> Meeting Minutes & Associated Documents [SNF.001.1491] at 1511

regulatory obstacle was removed.<sup>693</sup> It is also noteworthy that the committee concluded that routine testing should not yet be introduced, whilst also recording an estimate that the annual incidence of NANB Hepatitis in the UK following blood transfusion could be 10,000 cases.<sup>694</sup>

**31.480** It has already been observed (paragraph 31.416, above) that the minute prepared as a result of the ad hoc meeting on 13 September 1991 did not reflect, among other matters, the major concerns about funding in England and Wales that were explicit from at least 7 January 1991<sup>695</sup> and underlined by Dr Pickles' memorandum of 5 February 1991 (paragraph 31.271, above).<sup>696</sup>

**31.481** Dr Perry's note adds to a general sense of unease that the ACVSB was, at this stage, beginning to be less a helpful provider of relevant and well-directed expert scientific advice to government, and was becoming involved in wider policy issues. However, there was some force in Professor Zuckerman's point that it would be difficult for the ACVSB to approve for use a test that had not passed the regulatory criteria for use in its country of origin.

**31.482** There were significant events between 17 January 1990 and the next meeting of the ACVSB on 24 April 1990.<sup>697</sup> In February, Ortho distributed RIBA test kits for evaluation in the United Kingdom. On 8 February the AABB, the American Red Cross and the Council of Community Blood Centres issued joint guidelines in preparation for the introduction of anti-HCV testing of donations, a clear indication that licensing for domestic use in the near future was anticipated.<sup>698</sup> Intimation of the guidelines to the DoH 'stirred up a hornet's nest'. Mr Angus' comment that the expression reflected the unexpectedness of the US guidelines appears to be a reasonable interpretation. Professor Zuckerman and Dr Rotblat had both relied heavily on the likelihood of delay at the meeting of the ACVSB in January and Professor Zuckerman had written that the introduction of screening could not be delayed much beyond FDA approval. The unexpected progress towards introduction of screening in the USA went to the roots of ACVSB advice on policy.

**31.483** At the ACVSB meeting of 24 April, Dr Mitchell reported on the Abbott symposium he had attended in Chicago and the actions of the AABB immediately following the symposium in directing that anti-HCV testing should be introduced as soon as the FDA approved the test. It was reported that as at 24 April the FDA had not approved the test. The discussion moved to other matters. The idea that the UK could not delay the introduction of screening much beyond FDA approval was not articulated, so far as the minutes disclose. Rather the discussion focused on perceived shortcomings in the test systems available, all of which had been identified in one way or another before January 1990.

**31.484** It is appropriate to look at another significant event that had occurred before the meeting of the ACVSB in April: the Ortho symposium held in London in February. There were differing views of it. Professor Zuckerman and Dr Rejman presented adverse reports to the ACVSB. Dr Boulton's report of the symposium to Professor Cash recognised that

<sup>696</sup> Memorandum [PEN.016.0236]

<sup>697</sup> ACVSB Minutes [SNB.001.9761]

<sup>698</sup> Guidelines [SNB.001.9825]

there were defects in the Ortho test system, but he nevertheless felt strongly that it should be introduced at the earliest opportunity. He was concerned that the SNBTS would face future litigation from people infected with HCV in blood that could have been screened.<sup>699</sup> At the ACVSB meeting the risk of litigation was mentioned by Dr Mitchell as a factor he had noted at the Abbott symposium, but the minutes do not record any reaction to that.

**31.485** A further issue debated on 24 April was the advice to be given to donors.<sup>700</sup> Since this was a problem inherent in screening from the outset, widely acknowledged and obviously requiring a solution as soon as the possibility of any form of screening was first suggested, it is difficult to understand how it could take on such prominence in ACVSB deliberations at this stage. A solution along those lines did not depend on any insights that could only have been obtained by new information emerging between January and April 1990.

**31.486** In reality, the advice of Professor Zuckerman and Dr Rejman, possibly supplemented by the reservations of Dr Mitchell, prevailed. There was no commitment to introducing screening, even subject to FDA approval of the test systems for use in the USA.

**31.487** Looking at the record of the proceedings on 24 April, there are several reasons for concern. Papers from the London symposium were produced.<sup>701</sup> Dr Rejman's notes were brief and one can assume that members of the committee would have informed themselves fully. Professor Thomas had reported on the epidemiology of NANB Hepatitis. In particular, he had reported that most anti-HCV positive patients had mild, frequently sub-clinical, hepatitis after an initial incubation period, but half then made a complete recovery and half progressed to chronic liver disease. A proportion of NANB Hepatitis patients progressed to cirrhosis.

**31.488** While the minutes may have provided a less than comprehensive account of discussion, the impression left is that the meeting on 24 April 1990 failed to reflect an appreciation of the seriousness of infection for patients receiving blood, blood components, or products. There was no reference in discussion to Dr Lee's abstract, for example. She had reported that the use of Ortho kits had confirmed anti-HCV sero-positivity in *all* haemophilia patients with well documented NANB Hepatitis. While there were legitimate reservations about the sensitivity and specificity of the ELISA test at that stage, a balance was necessary that recognised the interests of recipients of human blood in whatever form. The minutes do not provide any comfort that the members of the committee had this in mind or gave it sufficient weight on 24 April 1990.

**31.489** Professor Leikola's comment in response to Dr Rejman's observation that the Ortho test was not sensitive or specific enough for reliable testing<sup>702</sup> was apposite: the tests were considered good enough by the Finnish authorities for screening to have been introduced there in early 1990. Dr Metters had noted at the meeting in April 1990 that France, Belgium, Luxembourg and Italy had all introduced anti-HCV testing. There is a distinct sense that a determination to pursue the best was becoming detrimental to finding a practical and acceptable solution to a real problem affecting the health of significant

<sup>701</sup> Report on Ortho HCV symposium [SNF.001.1628]

<sup>702</sup> See paragraph 31.208

numbers of NHS patients. Professor Leikola's assessment of the position is accepted. That position can be summarised as follows:

- The Ortho test was not a perfect test at this time.
- The experts contributing to the symposium in London would rightly take a critical approach to the tests, and emphasise what they had found.
- But to conclude on the basis of the information before the symposium that the test should not be introduced was a view he could not take.<sup>703</sup>

**31.490** Professor Leikola found the change of attitude in the ACVSB between January and late April 1990 'remarkable'.<sup>704</sup> While other countries were largely moving towards a policy of introducing the new tests, the ACVSB's reservations on routine screening had grown in that period. Dr Rejman, a DoH medical officer, had emerged as a contributor to the case against introduction. The next meeting of the committee was scheduled for 24 July, three months later. There was no sense of urgency. The study proposed would require a protocol to be prepared by the sub-committee nominated and then a considerable period to carry it out, whether the target number to be tested was 25,000, 50,000 or 100,000 individuals.

**31.491** The contrast between the negative tone of Dr Rejman's comments and Dr Boulton's observations is clear. The evidence concerning the Ortho symposium raises the issue, reflected in Dr Perry's evidence, whether consideration at this meeting of the topic of screening was dominated by reports and discussion from academic virologists.<sup>705</sup> Dr Perry's view at this time in the process was that the best was becoming the enemy of the good.<sup>706</sup> In his note to Professor Cash about the meeting he concluded:

[Gunson] and [Perry] felt there was sufficient data to justify testing now (based on U.S data suggesting 50% reduction in PTH) but the majority and the D.O.H. preferred more cautious approach.<sup>707</sup>

**31.492** Drs Gunson, Mitchell, Mortimer and Tedder constituted the study protocol sub-committee to organise the trial. It met on 23 May 1990. By letter dated 5 June 1990, Dr Metters brought forward the meeting of the ACVSB previously scheduled for 24 July.<sup>708</sup> In the light of 'subsequent events,' namely FDA approval of the ELISA test for use in the USA and 'some additional scientific information' that had become available, an extended study of RIBA and PCR techniques might not be appropriate. The next meeting of the ACVSB would be brought forward to 2 July. The questions to be addressed are set out in paragraph 31.215. They provided for a wide-ranging re-assessment of the approach to screening.

**31.493** At the meeting of the ACVSB on 2 July,<sup>709</sup> the committee concluded that it should recommend to Ministers that testing should be introduced, but that first there should be a pilot study comparing the first generation Ortho and Abbott tests to decide which test was better for RTCs to introduce.

<sup>706</sup> Day 68, page 136

<sup>707</sup> Dr Perry's report [SNF.001.1710] at 1712. As was observed in the submissions from the patient representatives, this was not cautious from the perspective of prospective recipients of HCV positive blood.

<sup>708</sup> Letter [SNB.002.0245]

<sup>709</sup> ACVSB Meeting Minutes 2 July 1990 [SNF.001.1705]

**31.494** The papers disclose that there had been additional information on the effectiveness of screening to reduce transmission of HCV infection. The extensive discussion at the previous meeting was not dealt with, and the resolution of the scientific issues then set out – if it occurred – is obscure. The most obvious substantial change was that the FDA had in fact approved the ELISA tests.

**31.495** While the decision of the ACVSB in July 1990 to recommend to Ministers that HCV screening should be introduced was policy advice of the kind properly within the remit of that committee, it is less easy to understand why the ACVSB appears to have sought to retain responsibility for deciding which test kit should be used by RTCs. On the face of it, that was very much an operational decision which could have been left to the ACTTD, members of which had long standing practical experience and expertise in evaluating and introducing new screening tests. At that point, however, there does not appear to have been a meeting of the ACTTD scheduled to take place in the then foreseeable future: it did not meet between 16 March 1990 and 8 January 1991.

**31.496** It was forecast that four months would be required for the pilot study, after finance had been agreed. At the meeting it was anticipated that the next meeting of the ACVSB would be in October. The date was later amended to 21 November, a date which appears to have allowed for completion of the pilot study. As noted at paragraph 31.233, Dr Gunson reported to the November 1990 meeting of the ACVSB that both the Ortho and Abbott first generation screening tests could be deemed to be satisfactory for routine use within RTCs from an operational viewpoint, and that the results of the supplementary testing would be the decisive factor when considering whether one test was better than the other. In the event, the final report was not available until February 1991.<sup>710</sup> Had the introduction of screening truly been dependent on the completion of this pilot study, the result of the decision of 2 July would have been that until its completion no decision would have been possible on advice to be given to Ministers as to the preferable test until its completion.

**31.497** There were conflicting views before the Inquiry on whether a completed pilot study was required before screening was introduced. Dr Mitchell and Dr Perry, for different reasons, thought that it was. Professor Leikola thought that comparative studies could have been carried out after introduction of screening. Professor Leikola's view appears correct. As it transpired, the study did not add much to the process apart from delay.

### *Eighth Meeting of the ACVSB*

**31.498** By the date of the November 1990 meeting of the ACVSB<sup>711</sup> enough information was available about the pilot study for Dr Gunson to give the information already noted. Equipment would be a factor, but the results of supplementary testing would be decisive in making the choice. After hearing Professor Tedder and Dr Mortimer, the Committee concluded that a combination of RIBA and PCR would provide a useful confirmatory service. Professor Zuckerman observed that, on the results available, it was impossible to choose between the tests. The Committee agreed that it was important to start screening as soon as possible.

---

<sup>710</sup> An Investigation of the Use of the First Generation Ortho and Abbott Anti-HCV EIA Screening Tests [SNB.001.9032]

<sup>711</sup> ACVSB Minutes 21 November 1990 [SNF.001.1777]

**31.499** Although there is no reference to a particular date in the minutes, there clearly was discussion of a start date for screening. Dr McIntyre's note<sup>712</sup> that Dr Metters had proposed 1 April 1991 is accepted as factually correct. Mr Canavan's note to Ministers dated 21 December 1990 indicated that routine screening was unlikely to be possible before 1 April 1991.<sup>713</sup> That was consistent with discussion of that date by the committee. Dr Mitchell's letter to Professor Cash dated 23 November<sup>714</sup> was in line with paragraph 10 of the minute. It was on that basis, rather than a precise set date, that Professor Cash contacted RTDs in Scotland to find out when they could begin routine testing. So far as the Inquiry has been able to discover, those who replied could all have commenced screening before 1 April 1991. Subject to the problems that arose later with the Gulf War, meeting that date would not have been a practical problem for RTDs in Scotland. At the November meeting, Dr Metters once more stressed the importance of a common date of introduction of screening throughout the United Kingdom. Since there was no technical or scientific basis for this view, it appears simply to have represented a re-assertion of the continuing policy position of Ministers as understood by the committee.

**31.500** In November the ACVSB discussed the counselling of HCV-positive donors. Dr Mitchell advised the committee that the issue had been discussed in Scotland and that a draft document was available which could form the basis of discussion at the meeting of the ACTTD which was to consider the matter. Since the ACTTD was at all times the committee likely to have the responsibility for resolving the practical issues relating to counselling, it is clear that this was a decision that could have been taken at any time over the long period during which the introduction of screening had been discussed by the ACVSB. Had the ACTTD been asked for advice on counselling and failed or delayed in providing it, matters might have been different. But on the evidence available, there was no such failure or delay, and consideration of arrangements for counselling was never a legitimate reason for the ACVSB to delay the provision of scientific advice to Ministers.

### **The policy of a uniform start date – implementation of screening**

**31.501** Items 7 and 5 of the series of issues identified by Inquiry Counsel noted at paragraph 31.431, can conveniently be taken together:

The formulation of policy regarding the co-ordination of the starting date for the introduction of screening in Scotland with the starting date for England and Wales, the flexibility of such policy and whether such policy as existed resulted in delay in the introduction of screening in Scotland;

and

Why was there a delay of almost ten months between the decision by ACVSB on 21 November 1990 to recommend the introduction of screening as soon as practicable and the introduction of screening in Scotland on 1 September 1991?<sup>715</sup>

<sup>712</sup> Dr McIntyre's note of the ACVSB Meeting held on 21 November 1990 [SGH.002.8501] at 8502. Dr Perry thought the proposed date might have been edited out of the minutes: Day 68, page 124.

<sup>713</sup> Note [SGH.002.7893] at 7896

<sup>714</sup> Letter [SNB.005.3696]

<sup>715</sup> Closing Submission – list of issues – Inquiry counsel [PEN.019.0843] at 0855 – questions 7 and 5.

*Uniform start date*

**31.502** As emerges from the discussion of November 1990, UK Government policy appears to have been static from its earliest articulation down to the end of 1990. Commitment to a unitary start date became almost an article of faith. There is no evidence that the Scottish Office Minister of State with responsibility for Health, or the Secretary of State were ever minuted by officials with a proposal that there should be a different, earlier, start date in Scotland than in the rest of the UK, or that this possibility was ever raised with Scottish Ministers. Without such a step, there was no mechanism by which the political implications of a suggested change of policy could have been addressed and resolved. While that may have been understandable during much of 1990, when it became clear in late 1990/early 1991 that the introduction of testing would be delayed in England, it is a matter of concern, given the public health issues involved, that the matter was not brought to the attention of Ministers in Scotland to consider the earlier introduction of screening.

**31.503** There was evidence that the consent of the Secretary of State to a start date of 1 April 1991 was implicit in the approval of the PES for 1991–92. In terms of accountability for public expenditure that was clearly so: the public accounts auditor would have found an appropriate vote authorising the expenditure on screening had it been commenced at any date after the beginning of the financial year. It would, however, be a total fiction to infer detailed knowledge on the part of Scottish Office Ministers of the practical implications and policy background to every line of the PES.

**31.504** What is clear is that there was marked reluctance on the part of Scottish officials to bring the question of implementation of screening to the notice of Ministers at all. A full submission was sent to UK Ministers on 21 December 1990.<sup>716</sup> Mr Canavan's note identified 1 April 1991 as the earliest practicable date. It is not obvious that there was any obstacle to a parallel course being taken in Scotland. Dr McIntyre understood the date to be 1 April 1991. It would have been appropriate for Scottish Office Ministers to have been informed. They were not. If there were good reasons for the delays in presenting a 'Hep C submission' to Scottish Office Ministers during the first half of 1991, they have not become clear in the course of the Inquiry. In the result Mr Forsyth, Minister of State with responsibility for health from September 1990, did not receive a submission until 24 July 1991,<sup>717</sup> by which time the commencement date of 1 September had been set in stone.

**31.505** Scotland's policy had been subordinated to the requirements of England and Wales, effectively the DoH. When Mr Panton wrote to the CSA on 8 August 1991 formally communicating the Minister of State's agreement to testing,<sup>718</sup> it was too late for any other course to be put to Mr Forsyth. It would, of course, be a matter of pure speculation to suggest any course of action that might have followed an earlier submission that Scotland should commence screening at an earlier date.

*Implementation of screening*

**31.506** The more substantial question is the second: why was there delay from November 1990 to 1 September 1991?

<sup>716</sup> Note [SGH.002.7893]

<sup>717</sup> Submission to the Minister on HCV Screening [SGH.002.7828]

<sup>718</sup> Letter [SGH.002.7802]

**31.507** Dr McIntyre had the impression that the ACVSB had reached a decision that screening should be introduced with effect from 1 April 1991. Dr Mitchell, who had been at the same meeting, thought that the exact date would be 'the earliest practical moment'. That discrepancy is, in itself, indicative of a lack of clarity about implementation. It is also noteworthy that the only steps Dr McIntyre appears to have taken on his return were to report orally to Mr Panton and to prepare a note of the meeting, which was sent to Mr Tucker and copied to the CMO, Mr Panton and Dr Skinner.<sup>719</sup> According to Professor Cash, Dr McIntyre had previously made the position very clear to him in relation to the ACVSB meetings. Dr McIntyre's position was that he would advise Professor Cash when he believed that there were things Professor Cash should be told.<sup>720</sup> A decision such as that reported by Dr McIntyre, namely that screening should be introduced from 1 April 1991, would fall within that description.

**31.508** As it happened, however, Dr Mitchell informed Professor Cash of the position, although without the specification of 1 April as the date. One could not be critical of the SNBTS response to this news: Professor Cash responded quickly to Dr Mitchell's letter of 23 November 1990<sup>721</sup> by writing to Directors on 27 November.<sup>722</sup> There was some uncertainty over the meaning of 'start date', but in the event that had no bearing on any relevant decision required in Scotland. Preparation for donor counselling was put in hand and instructed the ACTTD's thinking on the subject. Again, work in Scotland was ahead of the rest of the United Kingdom and did not adversely affect UK-wide progress towards testing.

**31.509** External events affected progress. The Gulf War changed the pattern of demand for blood components, generated a surge in blood donation and for a period into 1991 was an understandable block on progress towards routine screening. But in the early months of 1991, the CSA was on track to deliver funding which would have enabled commencement of screening on 1 April 1991.

**31.510** From the beginning of 1991, Professor Cash knew that funding for screening in England and Wales was a problem. He was present at the meeting of the NBTS/SNBTS liaison committee on 7 January 1991, where Dr Gunson explained his concerns about the failure of the DoH to decide on a start date, and indicated that funding was the major problem.<sup>723</sup> Uncertainty about dates persisted: on 16 January 1991, government commitment was limited to introducing screening 'as soon as is practicable', without a date being indicated.<sup>724</sup> Lack of funding was related to the UK Government policy position, noted by Dr Metters on 17 January 1990, that 'funding would have to be found from the existing health vote allocation'. The position in Scotland regarding funding was materially different.

**31.511** On 21 January 1991, Mr Tucker in the SHHD reported to Mr Panton a conversation he had held with Mr Canavan in the DoH. Mr Tucker had accurately foreseen slippage in timing, and had suggested setting a date of 1 April to prevent all parts of the UK being required to wait for the last area to be ready.<sup>725</sup> But he viewed this as a suggestion he made

<sup>724</sup> Policy memo [PEN.016.0259]

<sup>725</sup> Memo [SGH.002.7890]

to the DoH, rather than as a basis for action by the SHHD to set a date for Scotland.<sup>726</sup> He regarded the policy of a uniform start date as firmly established; the Scottish Minister 'would not have taken a different course'.<sup>727</sup>

**31.512** Dr Pickles' memorandum dated 5 February 1991,<sup>728</sup> which was copied only to Dr Metters, Dr Rejman and another official, paints a telling picture of the stage reached at the DoH. It emphasised the practical problems in the way of implementation, and the 'real concern about how the necessary money will get into the system'. Against this background, Dr Gunson's suggestion of a start date of 1 July seemed 'OK', though it would result in some stragglers being left behind. The memorandum was not copied to anyone in the SHHD. It suggests a distinct lack of urgency given the public health issues at stake.

**31.513** In Scotland, Professor Cash maintained the commitment to the commencement of screening at the same time in both Scotland and England. On 24 January 1991, he repeated the commitment of the SNBTS to a uniform start date; if pressed he would suggest 'a May/June date'. On 13 February, the SHHD learned from the DoH that it was hoped that screening would commence on 1 July. The SNBTS was specifically identified as a body not to be informed of this.<sup>729</sup> On 15 February 1991, Professor Cash wrote to Dr Gunson reiterating the SNBTS wish to stay in line with the NBTS/BPL. On the same day, Dr Gunson wrote to regional transfusion directors in England and Wales advising that screening would commence on 1 July 1991.

**31.514** The ACVSB met on 25 February 1991.<sup>730</sup> The need for 'proper' evaluation of the second generation Abbott and Ortho tests was emphasised. It was thought that the kits would 'in principle' be available from 1 July. It was noted that patent rights 'had not yet been determined'. There was no discussion of the problems anticipated. In particular there is no record that members were told that finance was a real concern. So far as the Minute discloses, that remained an internal issue for the DoH, as did the selection of a start date. Those were by this stage properly in the hands of the DoH (at least in so far as England and Wales were concerned).

**31.515** In the course of the 'difficult' telephone conversations on 23–24 March, Professor Cash learned from Dr Gunson that there was to be a further postponement. As he described it, only with great difficulty did he support Dr Gunson at the meeting of the ACTTD on 25 March 1991, where the ACTTD accepted the postponement.<sup>731</sup>

**31.516** On 27 March 1991, Professor Cash wrote to Mr McIntosh<sup>732</sup> and stated that it was clear the NBTS was struggling to meet the 1 July commencement date and that he believed there was a fundamental problem with financial resources. He copied the letter to Dr McIntyre (SHHD), causing concern among the civil servants who had access to it. Why he did not personally speak to the SHHD became an issue for the Inquiry. Professor Cash was asked in oral evidence why he did not confirm the SHHD policy position with them directly. He reiterated that, regrettably, 'Harold Gunson convinced me that SHHD had been party to the decisions that were made'.<sup>733</sup>

<sup>731</sup> Paragraphs 31.314–31.327

<sup>732</sup> Letter [SGF.001.2026]

<sup>733</sup> Day 82, page 76

**31.517** Professor Cash said that following his letter he spoke to Mr McIntosh, urging him to approach the SHHD and ask whether Scotland needed to continue to ‘hang in’ with the English dates.<sup>734</sup> He maintained that at this point he was firmly of the view that an approach needed to be made to the SHHD to consider decoupling the plans for Scotland from those for England and Wales, and expected Mr McIntosh to make the approach, which he would support as National Medical and Scientific Director.<sup>735</sup> Mr McIntosh did not accept Professor Cash’s account of briefing him on the current position in 1991 regarding the introduction of testing and suggesting to Mr McIntosh that he rather than Professor Cash should contact the SHHD.<sup>736</sup> Professor Cash’s account of wanting to see the plans for Scotland proceeding separately from those for England at this point was difficult to reconcile with his evidence that he did not confirm the SHHD position directly because he had been convinced by Dr Gunson that the SHHD was ‘party’ to the decisions made.

**31.518** On his return to complete his evidence, Professor Cash explained that as National Medical and Scientific Director he had to report ‘exclusively’ to David McIntosh. Mr McIntosh had ‘insisted that all communications from the SNBTS ... into the Scottish Office was his job’. Mr McIntosh had support from Jim Donald for this.<sup>737</sup> He said that he had no direct access, in terms of management line access, into the Scottish Office.

**31.519** This was not an entirely convincing explanation: Professor Cash had a long track record of direct communication with the SHHD when he considered that there were issues to address. The conflict in evidence between him and Mr McIntosh – whether Mr McIntosh was asked to take the initiative – casts doubt over the sequence of events. But it appears to be clear that no approach was made to the SHHD to re-consider a phased introduction of testing across the United Kingdom, rather than the existing ministerial commitment to unified action, in order to avoid the further postponement of screening beyond 1 July 1991.

**31.520** If issues concerning the introduction of screening were indeed matters of management, it would be difficult to reconcile that with Professor Cash’s communications with Dr Gunson over the issue. The question concerns Professor Cash’s role as National Medical and Scientific Director. From at least 5 June 1990 he had special responsibility for operational quality, and for research and development, and he was charged with convening and chairing the Medical and Scientific Committee of the SNBTS (MSC).<sup>738</sup> The MSC remit was professional and scientific matters. In contrast, the SNBTS Management Board was the body through which all key policy and strategic decisions were to be channelled.<sup>739</sup>

**31.521** The introduction of screening clearly involved professional and scientific matters within the remit of the MSC, as well as policy and strategic matters within the remit of the SNBTS Management Board. The selection of a start date would have required advice on technical feasibility. Funding would have been a matter of policy on which the SNBTS Management Board might offer views, but it would then have been for the SHHD and Ministers to take a policy decision. On no view of Professor Cash’s role as National Medical and Scientific Director was he entitled to negotiate and conclude an agreement with Dr

<sup>738</sup> Management of the SNBTS in the ‘90s – Part 1 – The Skeletal Structure [SNB.002.4674] at 4675-76

<sup>739</sup> *Ibid* [SNB.002.4674] at 4674

Gunson as to Scottish, much less UK, policy on the date for the introduction of screening, without reference to the MSC and the SHHD. That this is what happened is supported by the contemporaneous documentation; as the submission for the Scottish Government observed, there is no evidence from 1991 to support the suggestion that Professor Cash was in favour of a reconsideration of the policy of a common UK start date, and much that is against it.<sup>740</sup>

**31.522** Even on Professor Cash's account of events, direct discussions between him and Dr Gunson (who did not, in the opinion of Mr McIntosh, have executive authority for the NBTS)<sup>741</sup> had illustrated the vague nature of policy making for Scotland in relation to the introduction of screening. The manuscript note on the SHHD copy of Professor Cash's letter to Mr McIntosh dated 27 March 1991, implies that officials did not know until that point of the further postponement of the introduction of screening.<sup>742</sup>

**31.523** Formally, it was open to Scottish Office officials at any time to make a submission to the appropriate Minister, and onwards to the Secretary of State for Scotland, that the commitment to a uniform UK start date for the introduction of any form of screening, but specifically anti-HCV, should be withdrawn and that screening should be introduced in Scotland when the SNBTS regions were equipped, funded and fully prepared to implement the decision. It would have become a political issue for Scottish Office Ministers in the first instance, and no doubt thereafter for discussion with UK Departments, whether to make a change of direction.

**31.524** This is precisely what was to happen at the end of 1994 in respect of Hepatitis C look-back. Lord Fraser of Carmyllie, then Minister for Home Affairs and Health at the Scottish Office, was advised that the SNBTS was ready to proceed with look-back and that, on medical and legal advice, the Secretary of State and he had a duty to initiate the process notwithstanding earlier UK policy.<sup>743</sup> In the result, UK policy was changed. However, the obligation of Scottish Ministers to act independently of UK colleagues where Scottish health issues were concerned, was asserted unequivocally.

**31.525** In the end, problems of funding the NBTS in England and Wales to start screening pushed the start date for the UK back to 1 September 1991. Mr McIntosh's assessment of the position is accepted. The successive delays over the period March to September 1991 were exclusively a direct result of giving priority to the UK solidarity argument. That was underlined by the financial problems in England and Wales.

**31.526** The 'device' of presenting the implementation in Glasgow – along with Newcastle and two other centres – as a further study, was related to Newcastle's decision to take unilateral action. As a practical matter, the result was that for half of Scotland agreement on a UK-wide start date ceased to matter. In Edinburgh, testing began on 30 July 1991.<sup>744</sup> For the remaining parts of Scotland, UK solidarity may have been a significant disadvantage. In this regard, however, it has been pointed out to the Inquiry that in Dundee, contemporaneous documents suggest that assessment of, and familiarisation with, testing kits began in the middle of July, with all units producing other than negative results being withheld from issue.

## Summary and conclusions

**31.527** It is now necessary to try to draw the material together. The topic addressed in this chapter is conveniently viewed in two parts. First, there is the period between the summer of 1988 when the establishment of the ACVSB was first mooted, until the committee decided to recommend the introduction of screening for Hepatitis C on 21 November 1990. Secondly, there is the period after that decision when implementation was arranged, with screening finally starting across the UK on 1 September 1991. The Inquiry does not have enough information to be critical of the composition of the ACVSB, or to assess the dynamics of particular meetings. All those appointed were experts in their respective fields and there is nothing to suggest that they acted other than in good faith at all times. There is therefore no basis on which individual members of the committee or officials in attendance can be criticised in relation to the workings of the committee, and no observation made or conclusion reached by the Inquiry should be understood as making any such criticism.

**31.528** Reverting to the questions posed at the conclusion of the Inquiry,<sup>745</sup> the first three of those questions concern the construction of processes for reaching a decision about introducing screening, and implementing any decision to proceed. It is therefore appropriate to consider these matters together.

1. Until the establishment of the ACVSB, the UK did not have in place an appropriate mechanism for providing Ministers with independent scientific advice on the risks presented to NHS patients by transmission of viruses in blood, blood components and blood products. The decision to establish the ACVSB was therefore well founded.
2. The emergence of two committees – one established by the DoH in consultation with the other health departments of the UK and one established by the transfusion services – created a risk of confusion as to the respective remits of each and the relationship between them. The formation of the ACTTD appears to have been due to a perception on the part of Dr Gunson and Professor Cash that nothing had happened to progress matters, after the creation of a government committee had been mooted by Dr Harris in July 1988.
3. In retrospect, a better model would have provided for advice as to policy and arrangements for implementation to be coordinated, for example by the establishment of an ACVSB with a sub-committee, consisting mainly of members with transfusion expertise, to address the implementation of policy. Thus, what Dr Perry termed 'scenario planning' could have been addressed in a dedicated forum whilst policy was being finalised by the ACVSB.
4. There was a lack of clarity as to how there was to be implementation in Scotland of decisions reached by the committees. There was asymmetry in that the Director of the NBTS, Dr Gunson, served on the ACVSB whereas his equivalent in Scotland, Professor Cash, did not. The requirement of confidentiality relating to the proceedings of the ACVSB, coupled with a lack of routine communication back to the SNBTS, contributed to the perception in Scotland that there was little direct involvement in decision making. That said, it is not clear that the deliberations of the committee would have been influenced by additional Scottish representation, and it is clear that when the decision to recommend the introduction of screening was finally made by the

---

<sup>745</sup> See paragraph 31.431

ACVSB in November 1990, Scottish centres were well placed promptly to implement the decision.

**31.529** The fourth question posed related to factors which contributed to there being no decision until November 1990 to recommend to Ministers that screening should start as soon as practicable:

5. From around the end of 1989, the ACVSB became involved in more than expert scientific advice; the committee was considering wider policy issues and addressing the practical implementation of policy.
6. In retrospect, the meetings of the ACVSB on 24 April and 2 July 1990 were missed opportunities to recommend the earlier implementation of screening.
  - a) At the meeting on 24 April 1990, the committee was presented with a particular impression of the symposium held by Ortho in London in February. That impression appears to have influenced the committee against the test. Dr Boulton, Deputy Director of Edinburgh and South East Scotland BTS, had also attended the seminar, and reported on it to Professor Cash. The Inquiry considers that Dr Boulton more accurately identified and weighed the relevant considerations in suggesting to Professor Cash that screening should be introduced at the earliest opportunity than did the members of the ACVSB at their meeting of 24 April.
  - b) It had been pointed out by Professor Zuckerman at the beginning of 1990 that the introduction of screening could not be delayed much beyond FDA approval of the test, but it appears that the committee was taken by surprise by news that approval had been granted on 2 May 1990. When that occurred, as Burton J pointed out in *A v National Blood Authority*, it completed the three requirements set out in the minutes of the ACVSB meeting of 6 November 1989: successful pilot trials in the UK, the grant of FDA approval and the existence of a RIBA supplementary test (albeit not strictly a confirmatory test).<sup>746</sup> An inference that FDA approval was imminent could have been drawn: an export permit had been granted in the USA in November 1989 and guidelines for testing had been issued there in February 1990.
  - c) The decision at the meeting on 2 July 1990 to delay implementation until the completion of a further trial – this time to compare the Ortho and Abbott tests – was not warranted in the circumstances; local centres could have made their own choices and comparisons of the kits could have been made once screening had started.
7. In all the circumstances, a decision to recommend to Ministers the introduction of routine screening of blood donations for anti-HCV could and should have been taken by the middle of May 1990. It appears unlikely; however, that screening in any centre could have started much before the autumn of 1990. Having regard to the supplies of test kits available.

**31.530** The remaining questions concern the period after the decision to recommend the introduction of screening. The Inquiry has endeavoured to assess why there was a delay of almost 10 months between the decision by the ACVSB on 21 November 1990 to recommend the introduction of screening as soon as practicable and 1 September

---

<sup>746</sup> Judgment [PEN.017.0302] at 0393, paragraph 154

1991, the point from which donations across Scotland were all being screened. It has also analysed the original policy that introduction of screening should take place at the same time across the UK, and considered if involvement of the Scottish Health Minister earlier than July 1991 would have led to earlier introduction of screening.

8. It is relatively straightforward to explain as a matter of fact why the time elapsed. There was a delay of almost ten months because a policy set at the outset – that the introduction of screening across the UK should take place at the same time – was maintained despite some areas being ready to begin considerably earlier than others.
9. It is much less straightforward to explain why there was no deviation from this policy. The period 21 November 1990 to 12 June 1991 included a number of missed opportunities for more prompt introduction of screening in Scotland.
  - In the first place, if Dr McIntyre had communicated to Professor Cash his understanding that the date for introduction of screening was to be 1 April 1991, the efforts of the SNBTS would have been directed towards achieving that implementation date.
  - In the second place, if Mr Tucker had been less diffident in communicating his perception in January 1991 that ‘to delay for the slowest could mean a long wait’, there would have been an opportunity for the date of 1 April to be confirmed as the date for introduction of screening in Scotland.
  - In the third place, if Dr Pickles had copied her memorandum of 5 February 1991 to any officials in the SHHD, it would have been appreciated more clearly that the funding problems in England and Wales were delaying the introduction of screening in Scotland.
  - In the fourth place, if the SNBTS, especially Professor Cash, and Mr McIntosh had explained the situation fully to the SHHD at the end of March 1991, and had put to them the suggestion that Scotland was in a position to move ahead with the introduction of screening in July 1991 as previously intended, a decision to adhere to that start date could have been taken. Instead, Professor Cash in effect determined the policy for Scotland, by agreeing with Dr Gunson a postponement of the introduction of screening to 1 September 1991, to be ascribed to the need for evaluation of second generation test kits.
10. Any suggestion that taking one or more of these steps would have led to earlier introduction of screening involves a determination that the position of the responsible Minister in Scotland would have permitted different dates for the introduction of screening in Scotland and in England/Wales. It is not possible to make such a determination. Viewed now, the reluctance to bring the issue of when screening was to start in Scotland to the attention of Ministers seems odd; the proposition that authorisation of the setting of a date could not be sought until a date had been determined elsewhere appears surprisingly passive. It may be that officials took for granted that there would be no change in direction. But within Scotland, the ultimate responsibility for the safety of patients undergoing NHS treatment with blood and blood products was that of the Secretary of State and his Ministers. Serious problems in relation to the introduction of a measure which would improve that safety should have been communicated to them, in order that they could decide what should be done.

## CHAPTER 32

### AN INVESTIGATION INTO THE SYSTEMS IN PLACE FOR INFORMING PATIENTS ABOUT THE RISKS – ETHICAL CONTEXT

#### Introduction

#### *Scope of this part of the Report*

**32.1** This part of the Report comprises four chapters. They explore the issues raised by Terms of Reference 2 and 3 for the Inquiry:

2. To investigate the systems in place for informing patients treated by the NHS in Scotland of the risks associated with the use in their treatment of blood or blood products with particular reference to the risks of infection with the Hepatitis C virus and HIV.

3. To investigate the systems in place in Scotland for obtaining consent from, and testing for infection with Hepatitis C and HIV, patients treated with blood or blood products, and informing patients found to be so infected.

**32.2** This chapter looks at the development of the relationship between clinician and patient during the reference period. Chapter 33 deals with various aspects of the information provided to patients on HIV/AIDS and at the testing of patients for HIV. Chapter 34 deals with the same matters in respect of NANB Hepatitis/Hepatitis C. Chapter 35, *An Investigation into the Steps Taken to Identify the Individuals who were Infected (Look-back)*, deals with the methods available to identify patients put at risk of HCV transmission by treatment with blood or blood products, and the steps taken in that regard.

#### *Background to this part of the Report*

**32.3** As stated in Chapter 4 of the Preliminary Report, it was a recurring theme in the witness statements which the Inquiry obtained from patients and their relatives that many patients felt that they were given little or no information from their treating clinicians about the risk of infection to which they were exposed as a result of their treatment with blood or blood products. Many of the patient witnesses who received blood transfusions in the 1970s, 1980s and in the 1990s stated that they were not warned of the risk of transmission of infection. The reasons for patients receiving blood transfusions varied, as did the circumstances in which they required medical care. In some cases the circumstances surrounding a surgical procedure will hardly have been conducive to a rational discussion of the long-term risks potentially associated with transfusion, but in others, such as planned medical procedures, there would have been more ample opportunity for discussion of risks. Most patients with a blood disorder who provided statements commented that they were not warned of the risk of infection with HTLV-III/HIV or non-A non-B Hepatitis from the blood products they received, including cryoprecipitate and factor concentrates.

**32.4** The investigations discussed in this part of the Report arose against this background, and reflected the questions that the experiences of many patients and their relatives naturally and understandably prompted. At the most general level, there was a need to know how it came about that materials subsequently found to be infectious were used in treatment without the patient being made aware that there was a risk of transmission of viral infection. Questions expressing that need have ranged from simple, but sometimes desperate, pleas for information to enable people to understand how they, or their relatives, came to be infected with HCV or HIV, to accusations, sometimes angry, against clinicians

responsible for prescribing therapeutic materials capable of transmitting infection. Some patients felt that, as a result of not being warned of the risks of infection from their treatment, they were denied the opportunity to make an informed choice about the treatment they received.

**32.5** Furthermore, many patients complained that they were tested for HIV and/or Hepatitis C without their consent and knowledge. A large number of the witnesses expressed dissatisfaction about the manner in which their diagnosis with HIV and/or Hepatitis C was conveyed to them and about the information which they were given about these viruses. Many witnesses felt that the health implications of the viruses and other matters, such as secondary infection, were not adequately explained to them.

**32.6** In very general terms, the clinicians' position, set out in submissions on behalf of the NHS in Scotland, was that: 'In their interactions with patients, clinicians made every effort to communicate effectively in unprecedented circumstances'.<sup>1</sup> Further it was noted that testing blood samples without express consent was commonplace and acceptable by the ethical standard of the time.<sup>2</sup> With regard to advising patients of the results of their test results, it was stated on behalf of the NHS for Scotland that: 'the preponderance of evidence strongly suggests that patients were told of their diagnosis'.<sup>3</sup> They highlighted evidence which indicated the difficulties for patients of absorbing information, particularly bad news.

**32.7** The Scottish Government recognised, in its closing submissions, that communication between doctor and patient: 'is an important and sensitive topic. Good communication is fundamental to the clinical relationship, and a critical factor in obtaining informed consent to medical treatment or surgical procedures'.<sup>4</sup> It also recognised and welcomed the fact that attitudes to communication and consent had 'progressed significantly' in the last 25 years.

**32.8** These brief comments reflect differences in the evidence of fact: what actually happened in the course of clinical procedures over long periods of time; what protocols were in place for communication between clinician and patient; and whether the differences in recollection and report can be resolved. In this chapter, evidence relating to the development of generally recognised ethical rules and practices will be discussed. Controversial issues emerged and some of them have to be discussed at length in an attempt to define the professional standards in place from time to time. In later chapters these standards inform discussion of the evidence of what probably did happen as between clinician and patient in the particular cases reported. This chapter explores the issues more generally. Resolving the competing evidence of experts proved to be difficult.

### *Evidence*

**32.9** For the purpose of exploring the range of issues discussed in the four chapters of this part of the Report at the Oral Hearings of the Inquiry, the following topics were defined:

#### **HIV/AIDS**

- The information given to patients (or their parents) about the risk of AIDS before their treatment with blood or blood products.

---

<sup>1</sup> Closing submission by NHSScotland on information given about the risk of AIDS [PEN.019.0428] at 0436

<sup>2</sup> Ibid [PEN.019.0428] at 0432

<sup>3</sup> Ibid [PEN.019.0428] at 0436

<sup>4</sup> Submissions on behalf of the Scottish Government [PEN.019.0274] at 0309

- The tracing and testing of patients who might have been exposed to the virus through their treatment with blood or blood products.
- The information given to patients who might have been infected, or who were found to be infected, and their families.

### **Hepatitis C**

- The information given to patients (or their parents) about the risk of non-A non-B Hepatitis before their treatment with blood or blood products.
- The tracing and testing of patients who might have been exposed to the virus through their treatment with blood or blood products.
- The information given to patients who might have been infected, or who were found to be infected, and their families.

Evidence on these topics was taken from the written and oral evidence of patients and their relatives, doctors, nurses, other professionals, and officials.

### ***Expert guidance***

**32.10** It was recognised that the Inquiry would require expert guidance on medical ethics and Professor Vivienne Nathanson and Dr Charles Hay were asked to assist in this respect. Professor Nathanson had been the Director of Professional Activities at the British Medical Association (BMA) for 16 years before coming to give evidence. Before working for the BMA she qualified and practised as a specialist registrar in general medicine. Dr Hay was Chairman of the United Kingdom Haemophilia Centre Doctors Organisation (UKHCDO). He was an experienced haemophilia clinician with a long and distinguished career in haemophilia care.

**32.11** Professor Nathanson attended the Inquiry twice to give evidence on ethical issues and provided two reports in which she answered a series of questions posed by the Inquiry team. The first report<sup>5</sup> dealt with HIV and AIDS. The second report<sup>6</sup> dealt with NANB Hepatitis and Hepatitis C. Dr Hay prepared a report<sup>7</sup> on the communication of information to patients about hepatitis in which he explained his opinion of the information patients should have been given about NANB Hepatitis/HCV against the background of the changing scientific knowledge of the condition in the period 1974–1995. In addition, Dr Hay set his evidence on the relationships between haemophilia patients and their doctors squarely in the context of his clinical experience. He gave oral evidence, based on his experience in practice in haematology medicine from mid-1977 to the present day, on the information and advice he personally gave to patients, or their parents, of the risks of contracting, and the severity of, NANB Hepatitis/HCV.

### ***Scope of this chapter***

**32.12** Although the separation between the two viruses, HIV/AIDS and NANB Hepatitis/HCV, will be maintained in discussion in the following chapters, it is appropriate to set the scene for particular discussion of the questions that have arisen from the evidence by a more general discussion. It is necessary to understand the nature of the doctor-patient relationship at the beginning of the reference period and to follow some of the

---

<sup>5</sup> Professor Nathanson's first report to the Inquiry [PEN.012.0330]

<sup>6</sup> Professor Nathanson's supplementary statement [PEN.018.0419]

<sup>7</sup> Dr Hay's report on communication to patients about hepatitis [PEN.018.0961]

developments thereafter as background to the discussion of the provision of information to patients.

**32.13** The accepted understanding of the way in which doctors should interact with their patients developed during the reference period, as knowledge of the viruses emerged and changed, and clinical practice was adapted to reflect that understanding. In her written reports and in oral evidence, Professor Nathanson commented on the development of the core elements of the ethical practice of medicine during the reference period, as she saw them, such as consent to treatment and testing and communication with patients. In oral evidence she expanded on the interaction of developing medical knowledge and ethical practice:

I think the important issue here is that when you look at ethics, not only has ethics changed during the period in question, or at least the practice of ethics, what we would regard as best practice and what we would expect as the minimum standard but that that has also had to reflect the change in scientific understanding during that period, and the two things have to come together.<sup>8</sup>

**32.14** In considering the response of clinicians to the needs of patients for information it is necessary to bear in mind these two distinct, if interrelated, factors.

**32.15** The clinical settings confronted by medical practitioners vary widely. Most of the discussion in this chapter will relate to the treatment of patients with coagulation disorders, typically Haemophilia A or B, managed over long periods of time. Monitoring patients at regular hospital attendances in that context afforded opportunities for discussion and the informed selection of materials for therapy that would not exist in many other situations involving transfusion, such as surgery or general medical procedures. The treatment of general medical and surgical patients may involve single or multiple sessions with more or less opportunity for discussion, depending on the circumstances. Transfusion in a surgical setting may be elective, providing an opportunity for discussion, or in an emergency setting in which prolonged discussion of options could threaten the life the surgeon is anxious to save. Sometimes a patient is unconscious before the need to give a blood transfusion, possibly to save his or her life, becomes apparent. It is necessary to bear in mind that issues raised by urgency or the immediate demand for relief of suffering may be very different from those that arise from care of patients with chronic conditions. In the first place, however, the focus will be on therapy in relief of blood coagulation disorders.

**32.16** It was to become apparent that, while there was a very substantial overlap between the underlying ethical principles and rules applicable as they developed from time to time, their application to the doctor-patient relationship varied in relation to the specific viruses to which the Terms of Reference relate, HIV/AIDS and NANB Hepatitis/Hepatitis C. Patients were exposed to the risk of transmission of these viruses over very different periods (see Chapter 2, *Patients at Risk*) and the factors driving changes in professional standards varied as between them, both in terms of chronology and in the context of developing medical knowledge.

**32.17** This chapter will therefore deal with what the Inquiry has learned and been told about the history of the doctor-patient relationship from the 1970s to the present day and then more specifically with the development of the ethical background to information

---

<sup>8</sup> Professor Nathanson – Day 84, pages 1–2

given to patients about the tests they were undergoing, the illnesses from which they suffered and about relevant treatment, again from the 1970s onwards. It deals principally with the evidence on those aspects of medical ethics that are of specific importance for the purposes of the Report. It is not a history of medical ethics generally. Nor does it provide a critique of the witnesses' general evidence. Differences between Professor Nathanson and Dr Hay are examined where they are material to the Terms of Reference.

**32.18** In general, it cannot be emphasised too strongly that, as the history of events in Scotland and elsewhere unfolded, in relation to information to patients and the way doctors were expected to interact with patients, the changes that occurred were sometimes dramatic. In relation to knowledge of the relevant diseases, not only were there significant changes over time in the understanding among clinicians of their respective aetiologies and natural histories, developments in knowledge were not consistent across all relevant disciplines. Knowledge among many clinicians inevitably lagged behind cutting-edge research to some degree at any particular point in time. The scientific and clinical developments are fully dealt with in Chapters 8 to 10 (HIV/AIDS) and Chapters 13 to 16 (viral Hepatitis). In this context it is particularly important to avoid being wise after the event and to avoid viewing events and developments in the light of later insights – applying up-to-date clinical knowledge and ethical standards to periods when such rules as applied were at best inchoate versions of later statements of principle and developments in practice.

## Sources of ethical guidance

### *Pre-1980s*

**32.19** There is no central UK committee on healthcare ethics. Clinical advice to practising doctors is provided by the BMA and the General Medical Council (GMC).<sup>9</sup> The BMA has had a committee looking at medical ethics since 1849.<sup>10</sup> The committee provides general advice to doctors in the form of guidance notes and leaflets. In the course of the reference period there were a number of landmark stages, reflected in published guidance documents, which help trace developments. Less formal means of providing guidance to doctors were also adopted. As Director of Professional Activities at the BMA, part of Professor Nathanson's job consisted of answering questions from doctors in practice about ethical dilemmas – advising doctors on what they should do in the specific circumstances brought to her attention.<sup>11</sup> Contemporaneous published guidance from the BMA and the GMC was not the only means of providing advice and was therefore not the exclusive test available of what was considered to be ethical practice. However, published guidance provides an accessible measure of the formal steps taken by representative medical authorities to inform doctors of their ethical duties and assists in setting a chronological framework for discussing other issues.

**32.20** Professor Nathanson recounted the history of medical ethics over the last 40 years in her first report to the Inquiry. It is not necessary to trace all developments in this field for present purposes as the nature and extent of the developments that are relevant can be demonstrated more briefly.

<sup>9</sup> The General Medical Council registers doctors to practise in the UK. Its purpose is to protect, promote and maintain the health and safety of the public by ensuring proper standards in the practice of medicine.

<sup>10</sup> British Medical Association, *Medical Ethics Today: Its Practice and Philosophy*, 1993, BMJ Publishing Group, London XXV.

<sup>11</sup> Professor Nathanson – Day 37, pages 1–3

**32.21** At one level, the requirement for patients to have necessary information relating to their treatment was referred to in documents from as early as the 18th century. Professor Nathanson referred to a quotation from the case of *Slater v. Baker and Stapleton* in 1767 which stated in the context of surgery (before the advent of anaesthesia) that it was 'reasonable that a patient should be told what is about to be done to him, that he may take courage and put himself in such a situation as to enable him to undergo the operation'.<sup>12</sup> This case was referred to in the BMA publication *Medical Ethics Today: Its Practice and Philosophy (1993)* in which it was observed that the comment:

[P]erhaps foreshadows current thinking that most people fare best when they have a clear view of what is being proposed and its implications.<sup>13</sup>

**32.22** Professor Nathanson also referred to the rules on medical research promulgated in 1949 after the Nuremberg trials, stating that they were the first explicit modern statement of the right of every patient to consent to and therefore refuse any medical treatment. Rule 1 of the Nuremberg Code provided:

[T]he person involved should have the legal capacity to give consent; should be so situated as to be able to exercise free power of choice, without the intervention of any element of force, fraud, deceit, duress, over-reaching, or other ulterior form of constraint or coercion; and should have sufficient knowledge and comprehension of the elements of the subject matter involved, as to enable him to make an understanding and enlightened decision.<sup>14</sup>

**32.23** The context for the Rule was medical research and, in particular, experimentation on human subjects. Professor Nathanson commented:

Following the Nuremberg trials legal rules on medical research were put in place. While these were not then well known to doctors throughout the world [Rule 1] was the first explicit modern statement of the right of every patient to consent to, and hence to refuse, any medical treatment.<sup>15</sup>

**32.24** Until 1949, the BMA and its ethics committee resisted preparation of an ethical code.<sup>16</sup> In 1949, the BMA Council produced a 16-page booklet mainly concerned with relationships between doctors and members of other professions.<sup>17</sup> In 1974 it produced a booklet of 50 pages, including a full reprint of the current GMC rules, the Hippocratic Oath and relevant ethical codes, including the Declaration of Helsinki.<sup>18</sup> Professor Nathanson suggested that, at a very basic level, the change in the approach to ethics could be illustrated in the difference in scale between the 50-page 1974 booklet and the current edition which is produced on a CD-ROM and is just under 1000 pages.<sup>19</sup>

<sup>17</sup> Ibid

<sup>18</sup> Professor Nathanson's first report to the Inquiry [PEN.012.0330] at 0330. The Declaration of Helsinki is a set of ethical principles regarding human experimentation developed by the World Medical Association and adopted by the WMA General Assembly in June 1964. It has undergone six revisions since then. The current, sixth revision was adopted by the General Assembly in Korea in October 2008. It was addressed primarily to physicians, and emphasised the physician's duty to promote and safeguard the health of patients, including those involved in medical research. It provided that in medical research involving human subjects the well-being of the individual research subject must take precedence over all other interests.

<sup>19</sup> Professor Nathanson – Day 37, pages 15–17

While superficially attractive, that could only be a sufficient measure of change if the publications were the sole source of guidance on ethical practice. However, as stated in paragraph 32.19 above, the BMA also produced specific advice sheets and guidance notes to its practitioners on a variety of areas and gave advice to doctors who contacted its ethics advice services. The proliferation of less formal advice suggests that the scale of change was even greater. However, on any view, the change in scale of the handbook reflects an appreciation of a growing need for formal written advice over the period that is relevant to this Report.

**32.25** More fundamentally, the nature of the advice given by the BMA to members has varied widely, reflecting the ethical mores and standards of the times. A reviewer of the 2003 edition of *Medical Ethics Today*, perhaps cynically, captured the flavour of the BMA's 1974 booklet from a modern medical perspective:

The 1974 edition ... provided guidance on important matters such as whether a consultant or a GP should enter the room first when both visited a patient.<sup>20</sup>

**32.26** Both the hierarchical structure of the profession and the paternalistic attitude towards patients were reflected in the 1974 guide. The culture of the time was summed up in a quotation from Dr CO Hawthorne who was the Chairman of the BMA Central Ethical Committee for many years. He was reported to have written between the wars that:

In the relations of the practitioner to his fellows, while certain established customs and even rules are written and must be written, the principal influence to be cultivated is that of good fellowship. Most men know what is meant by 'cricket' and the spirit of the game. Difficulties and differences will arise, but most of them can be successfully met by mutual goodwill and recognition of the other fellow's point of view.<sup>21</sup>

**32.27** As Professor Nathanson noted, this statement seemed to envisage a practitioner who already knew what the ethical rules were. At that time there was little in the way of specific guidance. She noted that the only reference to patient consent in the first edition of this guide related to the particular issue of organ donation. Academic texts discussed consent but it was rare for patients to question doctors' advice and consent was seen as a non-contentious issue.<sup>22</sup>

**32.28** In her evidence, Professor Nathanson undermined the notion that it could be assumed that practitioners would know the ethical rules. By way of background, she said that, in reality, the teaching of ethics lacked consistency and was of variable quality. In the 1970s, for more general ethics teaching, most medical students in London were educated by attending voluntary lectures given by the London Medical Group, an informal group of practitioners. Studies by the Institute of Medical Ethics in 1987 and 2006 demonstrated a continuing deficiency in ethics teaching of medical students and noted that, although the topic was a course requirement, it was rarely part of the final examination. The subject was taught in every medical school but there was, and remains, concern at the BMA about the consistency and quality of teaching. Although the teaching of medical ethics

<sup>21</sup> Quoted in Professor Nathanson's first report to the Inquiry [PEN.012.0330] at 0330

<sup>22</sup> Professor Nathanson's first report to the Inquiry [PEN.012.0330] at 0330

could be an independent part of the course structure, often it has rather depended on interested and knowledgeable clinicians teaching ethics as an additional element within a clinical discipline.<sup>23</sup>

**32.29** The publication of Ian Kennedy's 1980 Reith lectures, 'The Unmasking of Medicine', had a profound impact.<sup>24</sup> It advocated a more patient-centred approach to medicine in which patients were seen as partners in investigation, management and treatment decisions.

**32.30** According to Professor Nathanson, there was a shift in the period between 1974 and 1980 towards more guidance on specific ethical issues in response to clusters of queries about the correct approach to take in particular clinical situations.

**32.31** With regard to blood transfusion, 'Notes on Transfusion' issued to UK hospitals by the Department of Health and Social Security in 1973 required a record of every transfusion to be made in the patient's case notes.<sup>25</sup> It emphasised that 'the main reason for accurate recording is the protection of the patient'. No mention was made in these notes or their revised version in 1984 of patient information or of consent.<sup>26</sup> According to Dr Derek Norfolk '[i]nformed consent for blood component transfusion does not appear to have been a major issue for clinicians in the 1970s although there was increasing awareness following the emergence of HIV in the 1980s'. In the UK consent for transfusion has not been formalised and, in the surgical setting, has been regarded as part of the normal process of obtaining consent for the overall procedure.<sup>27</sup>

### 1980s

**32.32** The first BMA handbook on medical ethics was published in 1980 and revised in 1981 and 1984.<sup>28</sup> The 1980 BMA handbook, which was written by a sub-committee of doctors, gave more situation-specific advice and, in addition to the handbook, the BMA continued to produce advice sheets and guidance notes (sometimes on broad issues and sometimes focused on very specific issues) for its practitioner members on a variety of areas and gave advice to doctors who contacted its ethics advice services.

**32.33** The style of the 1980s publications before 1988 was to give ethical guidance through a list of generally agreed precepts. That style was abandoned in 1988, when, according to the 1993 publication *Medical Ethics Today: Its Practice and Philosophy*, the handbook set out 'the influences which give rise to the general moral and ethical order and set out principles as a basis for studying practical problems'.<sup>29</sup> The approach adopted by the BMA in 1988 is important for the purposes of this Inquiry, having regard to the evidence of the two principal witnesses dealing with ethical issues, and in particular the use by Professor Nathanson of the 1988 texts to explain wider ethical issues. However, reviewers were not uniformly of the view that the book succeeded in its objectives, as noted below (paragraph 32.45).

**32.34** In addition to BMA guidance, the GMC also published advice. In 1980 the advice produced by the GMC took the form of a list for doctors of what might constitute poor practice and lead to allegations of professional misconduct. By way of contrast, today

<sup>29</sup> Ibid

the GMC produces detailed advice of what constitutes good practice rather than bad. The GMC advice on consent has developed the concept of patient autonomy and, in this area also, the GMC now gives advice on what builds good practice rather than listing bad practice that could result in disciplinary issues. The change in emphasis and approach is stark: over time the GMC's guidance on ethics has become more prescriptive, directing doctors as to what best practice requires.<sup>30</sup>

**32.35** If the brief BMA ethics booklet published in 1974 reflected the attitudes of doctors and patients at the time, little appears to have changed in relation to general attitudes by 1980. Professor Nathanson contrasted BMA advice in 1980 with the more developed position in 1988.<sup>31</sup> In relation to consent, in 1980, the BMA stated:

The patient's trust that his consent to treatment will not be misused is an essential part of his relationship with his doctor.<sup>32</sup>

In 1988, the equivalent passage (quoted in full at paragraph 32.44 below) stipulated for patient consent before any investigation and treatment was carried out.

**32.36** In terms of good ethical practice, as at 1980 there was no specific requirement for consent, or any related procedure. Consent to treatment was still assumed rather than prescribed. By 1988, as Professor Nathanson observed, there was 'increasing comfort in using formal ethics language and concepts in describing the basic principle'.<sup>33</sup>

**32.37** In the interval between 1980 and 1988, a significant development was the adoption by the World Medical Association in October 1981 of the Declaration of Lisbon, a statement on the rights of the patient which provided that:

A mentally competent adult patient has the right to give or withhold consent to any diagnostic procedure or therapy. The patient has the right to the information necessary to make his/her decisions. The patient should understand clearly what is the purpose of any test or treatment, what the results would imply, and what would be the implications of withholding consent.

The patient has the right to refuse to participate in research or the teaching of medicine.<sup>34</sup>

**32.38** The Declaration was the earliest significant, and relevant, general statement on patient consent drawn to the attention of the Inquiry. The rights of a mentally competent adult patient were comprehensively formulated. It was a clear indication, from the autumn of 1981, of recognition by the international medical community of the patient's right to information relevant to, and to participate in any decision on, investigation and treatment, and participation in research. However, acceptance of the statement as part of a definitive code of ethical conduct would inevitably depend on its adoption by national authorities for their own jurisdictions. In the event, the Declaration came after and was not reflected in the BMA's 1980 statement. So far as drawn to the attention of the Inquiry, BMA publications did not reflect the general Lisbon principle of explicit and informed consent until 1988.

**32.39** In May 1988, the GMC set out guidance specifically in relation to HIV and AIDS in a publication entitled *HIV Infection and Aids: the Ethical Considerations* (the GMC Guidance of 1988).<sup>35</sup> It narrated the Council's expectations of doctors intending to carry out investigative procedures related to these conditions and stipulated the need for patient consent, whether explicit or implied, to the procedures being undertaken. The guidance stated that the Council believed that the same principles should apply generally. It appears from Professor Nathanson's explanation of the immediate past history of the guidance on AIDS that the guidance may have related more to what the GMC *wished* doctors to aspire to rather than to established and generally recognised rules of behaviour.

**32.40** As Head of Ethics at the BMA between 1987 and 1989, Professor Nathanson attended a GMC meeting in April 1987 as an observer, ensuring cross-representation in the discussion of ethical issues. A paper on the benefit of routine testing and testing without consent, probably written by GMC staff on the basis of debate at previous committee meetings, was discussed. One of the members, a doctor in general practice, advocated that doctors should be able to test patients for HIV infection without consent. After debate it was decided that it would be unethical to carry out such tests without consent. Professor Nathanson recollected, however, that in about 1986–87 the BMA had actually voted for a policy which allowed doctors to test without consent. As soon as the policy was agreed the BMA took legal advice and they were advised that testing without consent was illegal. The policy was reversed the next year at the BMA's annual meeting of 600 representative doctors. In fact the BMA had received conflicting advice from two QCs on the topic. The rationale of the advice which was followed was that because the HIV test was not a standard test the implied consent given for more general tests, like a full blood count, did not apply and specific consent was therefore required.<sup>36</sup> These discussions, in committee and more broadly, eventually resulted in the GMC Guidance of 1988.

**32.41** It is worthy of comment that, in the legal opinion followed by the GMC, reasons specific to the HIV test were persuasive, differentiating it from 'standard' testing. Specific consent was required for anti-HIV testing, implicitly recognising that 'standard' testing was in a different position. Professor Nathanson's anecdote demonstrated clearly that, until the BMA meeting in April 1987 and the GMC Guidance of 1988, the question of consent to investigation and treatment was capable of generating serious debate even among the members of representative bodies' ethics committees, quite apart from dividing the BMA's legal advisers.

**32.42** That debate was not reflected in the publications in 1988. (In addition to *HIV Infection and Aids: the Ethical Considerations* a BMA publication *Philosophy and Practice of Medical Ethics* was revised that year – see paragraph 32.43). In the GMC Guidance of 1988, in a section headed 'Consent to Investigation or Treatment', the GMC stated:

12. It has long been accepted, and is well understood within the profession, that a doctor should treat a patient only on the basis of the patient's informed consent.<sup>37</sup> Doctors are expected in all normal circumstances to be sure of their patient's consent to the carrying out of investigative procedures involving the removal of samples or invasive techniques, whether those investigations are performed for the purposes of routine screening, for example in pregnancy or

<sup>35</sup> *HIV Infection and Aids: the Ethical Considerations*, General Medical Council, May 1988 [PEN.016.1165]

<sup>36</sup> Professor Nathanson – Day 37, pages 31–35

<sup>37</sup> 'Informed consent' had a specific meaning in the USA, where it was a legal requirement. It was not a requirement of UK law, and the use of the expression in this context is 5 questionable.

prior to surgery, or for the more specific purpose of differential diagnosis. A patient's consent may in certain circumstances be given implicitly, for example by agreement to provide a specimen of blood for multiple analysis. In other circumstances it needs to be given explicitly, for example before undergoing a specified operative procedure or providing a specimen of blood to be tested specifically for a named condition.

....

13. The Council believes that the above principles should apply generally, but that it is particularly important in the case of testing for HIV infection, not because the condition is different in kind from other infections, but because of the possible serious social and financial consequences which may ensue for the patient from the mere fact of having been tested for the condition.<sup>38</sup>

**32.43** The BMA publication *Philosophy and Practice of Medical Ethics* (in revised format in 1988) provided BMA guidance of more general application.<sup>39</sup> It discussed for the first time the underlying philosophical basis of medical ethics.<sup>40</sup> Professor Nathanson said that this allowed doctors to make a judgment for themselves when they came across a situation which had not been specifically detailed, based on the general principles underlying specific guidance. Each subsequent edition of this book has also included a section about unresolved dilemmas where the correct approach was still held to be in the balance. The 1st edition already recognised that there were many situations where the nuancing of the particular patient's situation was so important that doctors had to be given information to help them understand how to judge different things, and to recognise that medical ethics was not fundamentally about whether one or another approach or action was correct, but was about balancing different people's rights, responsibilities and duties.

**32.44** In relation to consent, the passage in the 1988 BMA ethics guide equivalent to the brief statement in the 1980 publication quoted in paragraph 32.35 had become more specific, apparently reflecting the thinking in the Declaration of Lisbon. It stated:

The basis of any discussion about consent is that a patient gives consent before any investigation and treatment proposed by the doctor. Doctors offer advice but the patient decides whether to accept it.<sup>41</sup>

**32.45** The 1988 guide did not meet with universal approval. In a review article in the *Journal of Medicine and Philosophy*,<sup>42</sup> written from a US point of view, it was stated:

Handbooks of medical ethics serve to put a little flesh on the bare bones of a professional code that is necessarily brief. Indeed in its previous incarnations (1980 and 1984) this is just what the British Medical Association's *Handbook* sought to do. The latest edition, retitled *Philosophy and Practice of Medical Ethics*, has a more ambitious aim: "...to set out the arguments and counter-arguments which lead either to universally accepted ethical principles or to consensus views" (... emphasis added). ... Unfortunately, the B.M.A's attempt fails. "Unfortunately", because there is a real need in Britain for thoughtful

<sup>42</sup> Kessel, 'Book Review: British Medical Association: 1988, *Philosophy & Practice of Medical Ethics*, BMA, London', *Journal of Medicine and Philosophy*, 1989; 14/6:709–710 [LIT.001.5839]

discussion of these issues, and especially for one that can reach Britain's doctors. For despite the work of the London Medical Group, and its progeny around the country, and of the efforts of the Institute of Medical Ethics and its *Journal*, doctors and their patients are very rarely exposed to principled arguments concerning issues such as ... informed consent and treatment decisions ... (all topics mentioned in the B.M.A book).

Viewed from a US perspective, the handbook failed to fill the gap in teaching of ethics already noted at paragraph 32.28 above. Perhaps of greater importance, it failed, in the reviewer's opinion, to meet its own aim of providing material for the debate required for consensus to emerge on ethical principles.

### 1990s

With effective screening of donations for anti-HCV from 1 September 1991, the cohort of patients who were carriers of the virus or its antibody as a result of previous therapy but who remained untested for anti-HCV necessarily grew smaller in a relatively short space of time. Most of them would have had a history of testing with the technology available over previous years and would have known that their medical histories reflected the results of tests for anti-Hepatitis B, other virus infections and liver function and other biometric tests. However, in large part due to the debate on testing for HIV, there was, in Professor Nathanson's words, a sea change in the approach to medical testing, and in relation to consent to treatment.<sup>43</sup>

**32.46** The BMA's *Medical Ethics Today: Its Practice and Philosophy* (1993) was the first relevant publication in the 1990s. It offered a summary of the ethical background to the advice set out, as well as the advice itself. The legal basis of the advice was said to have been set out in *Rights and Responsibilities of Doctors* published by the BMA in 1992. The 1993 text stated that, as a prerequisite to choosing treatment, 'patients have the right to receive information from doctors and to discuss the benefits and risks of appropriate treatment options'.<sup>44</sup> The clinicians assisting the patient in making their decision must offer information in an appropriate manner to ensure the patient understands its relevance and is able to ask questions. In Professor Nathanson's view, an understanding developed from the late 1980s to early 1990s that meaningful consent was important. The patient should have the opportunity to make a free and sufficiently informed decision and a doctor could not do anything to a conscious and competent patient without their agreement.

**32.47** In terms of content, and expression, the 1993 handbook reflected development of the philosophical underpinning of the doctor patient relationship. In relation to consent, now expressly twinned with refusal of consent, it stated:

The relationship between doctor and patient is based on the concept of partnership and collaborative effort. Ideally, decisions are made through frank discussion, in which the doctor's clinical experience and the patient's individual needs and preferences are shared, to select the best treatment option. The patient's consent to be examined and to receive treatment is the trigger which allows the interchange to take place .... [T]he basic premise is that treatment is undertaken as a result of patients being actively involved in deciding what is done to them.<sup>45</sup>

<sup>43</sup> Professor Nathanson's first report to the Inquiry [PEN.012.0330] at 0337

<sup>44</sup> British Medical Association, *Medical Ethics Today: Its Practice and Philosophy*, 1993, BMJ Publishing Group, London, page 3

<sup>45</sup> *Ibid* at page 1

**32.48** Professor Nathanson sought general support for her views on the doctor-patient relationship in relation to therapy from the GMC advice on *Serious Communicable Diseases* published in October 1997.<sup>46</sup> She quoted the second half of paragraph 4 from that document:

Some conditions, such as HIV, have serious social and financial, as well as medical, implications. In such cases you must make sure that the patient is given appropriate information about the implications of the test and appropriate time to consider and discuss them.<sup>47</sup>

**32.49** This paragraph was said by Professor Nathanson to be particularly important. It was the first reference (as late as 1997) by the GMC to the non-medical, as well as the medical, implications of diseases. There are conditions other than HIV with social, financial and other similar implications and, while many practitioners may well have thought that 'best practice' implied these should be discussed, this was the first time the GMC made that obligation explicit. Though the title of the booklet was *Serious Communicable Diseases*, Professor Nathanson thought that the guidance set out in this particular section applied to other conditions where there were equivalent consequences. In those cases also the consequences should be discussed. By way of example, she referred to a diagnosis of epilepsy, which would have immediate serious implications, but is not a 'serious communicable disease'. It would, in her view, nonetheless come within the scope of paragraph 4 of the *Serious Communicable Diseases* advice leaflet. She stressed that the consequences of a diagnosis (of any condition) are not solely medical and that other factors such as family circumstances, a patient's role in the community and the workplace have to be considered. In her view, paragraph 4 reflected good practice generally.<sup>48</sup>

**32.50** In 1998, long after the events that are relevant to the Terms of Reference of the Inquiry, the position on consent became more explicit and clear. The GMC produced *Seeking patients' consent: the ethical considerations*.<sup>49</sup> This highlighted the patient's right to information about their condition and the treatment options available, the complexity of the treatment and the risks associated with the treatment procedure, going into some detail about the information which patients might want to have or ought to know before reaching a decision. It provided:

Successful relationships between doctors and patients depend on trust. To establish trust you must respect patients' autonomy – their right to decide whether or not to undergo any medical intervention even where a refusal may result in harm to themselves or in their own death. Patients must be given sufficient information, in a way that they can understand, to enable them to exercise their right to make informed decisions about their care.<sup>50</sup>

**32.51** In 2001 the Department of Health produced a reference guide to consent. In reviewing some of the existing sources of advice the guide commented that the 1998 GMC publication had gone further than the case law required in stating that doctors should do their best to find out about patients' individual needs and priorities when providing information about treatment options and in emphasising the duty to provide truthful

<sup>50</sup> Ibid

answers if a patient asks specific questions about procedures and associated risks.<sup>51</sup> The reference guide noted more generally that the standards expected of health professionals by their regulatory bodies may at times be higher than the minimum required by law.

**32.52** The Scotland Act 1998 and the Human Rights Act 1998 gave direct legal effect in the United Kingdom to the rights enshrined in the European Convention on Human Rights. The Department of Health's *Reference Guide to Consent for Examination or Treatment* mentioned above, set out the Department's understanding of the English common law relating to consent and the possible implications of the Human Rights Act 1998 for English medical law.<sup>52</sup> For present purposes differences between Scots and English law are not material. Among the Articles of the Convention that were thought likely to be relevant to the law, existing and developing, were Article 2 (protection of right to life), Article 3 (prohibition of torture, inhuman or degrading treatment), and Article 5 (right to liberty and security).

**32.53** In 2003 the BMA published general ethics advice as the second edition of *Medical Ethics Today*.<sup>53</sup>

**32.54** The published texts on ethics noted thus far reflect increasing sophistication in the analysis of ethical issues and in the presentation of rules and guidance for doctors to follow in ensuring good ethical standards. Each stage in the development provides focus for discussion as to whether the progression was simply expressive of an ethical standpoint that had been reached independently and was recognised in the published text or reflected innovative thought and the introduction of ideas that would not necessarily have been recognised by doctors generally prior to adoption by the BMA or the GMC as formal statements for publication.

### **The development of relationships between doctors and patients from the 1970s**

**32.55** Medical practice up to the 1970s was described as having been 'paternalistic': doctors felt that they had the necessary knowledge to deal with patients' needs and, as Professor Nathanson put it:

[D]octors would tell patients what they thought the patient ought to know and they would tell the patient what they were going to do as doctors to the patient.<sup>54</sup>

**32.56** Many of the medical witnesses who gave evidence to the Inquiry confirmed Professor Nathanson's description of the paternalism that was endemic at the beginning of the reference period. Dr Winter, who was for most of his career a Haemophilia Director, gave as an example the fact that, when he was working as a leukaemia doctor in 1980, it was by no means standard that a patient would be told about the diagnosis of a serious condition. At that time, it would be normal to speak to the patient's family first to find out if the patient would want to know about the diagnosis. Sometimes the next of kin would say that they did not want the patient to be told. He explained that there was no culture of doctors and nurses working with patients. A patient was 'a passive vehicle with an illness'. The patient went into hospital where an 'active vehicle' – the doctor or the nurse – made the patient better. A patient was not expected to have a view about treatment;

<sup>54</sup> Professor Nathanson – Day 37, page 11

rather, they would be told their treatment and would not be offered any choices about it. Dr Winter thought that this was particularly the case with haemophilia patients who had usually been seeing the same nurse and same doctor at the same centre for years. This made patients with haemophilia very trusting of their doctors and more passive.<sup>55</sup>

**32.57** Professor Nathanson put the matter bluntly:

In the late 1970s many doctors did not tell patients the whole truth, especially where that truth was of a diagnosis of an incurable illness. This was the well-intentioned legacy of Thomas Percival's influential text on medical ethics.<sup>56</sup> The intent was to shield patients from disturbing information. The duty of beneficence was interpreted as an obligation to be reassuring rather than honest.<sup>57</sup>

**32.58** Professor Forbes acknowledged the existence of paternalism in the early days.<sup>58</sup> This position was also confirmed by the one of the patient witnesses in her written statement. She was a retired nurse who contracted HCV from a blood transfusion in the late 1980s. She captured the atmosphere of the period when she was in employment and provided an illustration of the 'paternalistic' doctor-patient relationship that persisted at the material time:

When I received the blood transfusions, nothing was discussed with me regarding the benefits and risks of a blood transfusion. This was not done in those days. When I worked as a nurse in the 1970s and the early 1980s, I gave blood to patients. You never discussed the risks or benefits of this with patients although you maybe told them to watch for a reaction. I was not informed of a risk of infection from any of the blood transfusions. I was not given an opportunity to refuse the blood transfusions. You just did what you were told.

**32.59** Professor Nathanson noted that there has been a continuing move from this essentially paternalistic, 'doctor-knows-best' culture to a working relationship where the patient is fully involved in decision-making, or 'patient-centred medicine'. The emergence of AIDS appears to have accelerated this move. Changes occurred, according to her evidence, due to improvements in doctors' education and training, including improved teaching of medical ethics and training in communication skills so that doctors could speak with patients and relatives in a sensitive manner.<sup>59</sup> Although, in general, '[t]he earlier the time frame under consideration the commoner an essentially paternalistic approach would have been'<sup>60</sup> progress has not been uniform: the attitudes and practices of individual doctors changed at different rates within a broad pattern of historical change.

**32.60** Professor Nathanson commented that many doctors had begun to depart from the historic, paternalistic, approach early in the reference period and began instead to develop a more equal relationship with patients.<sup>61</sup> From the whole evidence on this topic, it appears that the culture of paternalism subsisted beyond the end of the 1970s and characterised practice widely, if not universally, in the early 1980s when formal ethical statements began to appear. The timing of these changes, and the timing of general acceptance that ethical principles had changed, are issues in this chapter.

**32.61** It was not suggested that the BMA handbooks published in 1980, 1981 and 1984 pointed to a significant change in or development of general principles. The advice given in these handbooks was situation-specific until 1988.

**32.62** In the period between 1980 and 1988 the AIDS epidemic struck and the advent of that disease brought about a major change in perception of the relationship between doctor and patient and in clinical practice. It is probably fair to say that the emergence of AIDS and the public and medical responses to it have had a more profound effect on relationships between doctors and patients than any other single event. Not only did it affect attitudes generally, it also impacted on a wide range of specific ethical issues, such as the need for informed consent to testing and treatment. Statements on medical ethics, published in and after 1988 after AIDS became a reality for coagulation disorder patients in the UK, reflected those changing attitudes.

**32.63** As noted above (paragraph 32.42) the statements in the GMC and the BMA 1988 publications were introduced as reflecting long accepted practice. In formulating new rules, as in 1988, it is understandable that bodies such as the BMA and the GMC should seek support in principles thought to be implicit in earlier practice. It is an important stage in the development of any system of regulation of professional behaviour when one can distil from accumulating evidence of particular instances of conduct, on one side of acceptability or the other, a principle or rule of general application. However, the formulation adopted may nevertheless understate what may be a considerable degree of innovation, especially where a regulatory or representative body is seeking clearly to express current expectations of practitioners' approaches to practice.

**32.64** When the stage is reached at which formal expression of principles and rules is appropriate, it is not unusual to find precedents cited.

**32.65** It would not, however, be appropriate to infer from the juxtaposition of the references in Professor Nathanson's evidence that there was a common basis for advice spanning two centuries. The context of the Slater case (see paragraph 32.21) conjures up an image of procedures, life-threatening in themselves, requiring the patient to prepare for all eventualities rather than a rational discussion of options: the doctor had to tell the patient what he was about to do and warn of possible outcomes. The modern approach to providing information and supporting patient choice has much more recent origins.

**32.66** Professor Nathanson's observation, that Rule 1 of the Nuremberg Code (see paragraph 32.22) was the 'first explicit modern statement' of the right of every patient to consent to and hence to refuse any medical treatment, points to a problem inherent in her approach to describing generally accepted standards of ethical conduct. She construed Rule 1 of the Nuremberg Code as expressing the right of every patient to accept or refuse medical treatment. She accepted, however, that the rules would not have been well known to doctors, not just in the United Kingdom but throughout the world. Since this was, on her approach, the first explicit modern statement of the rules, it became necessary to consider the evidence which had a bearing on a broadly based ethical obligation to recognise the patient's rights, apart from their formulation in formal statements in the 1980s.

**32.67** Given the clear evidence noted above of the 'paternalistic' attitude of doctors to patients, it is not possible, on the evidence before the Inquiry, to form a view that in the 1970s proper ethical practice depended on, or drew heavily on, the Nuremberg Rules, or historical judicial observations adapted to particular situations.

**32.68** It is perhaps not surprising that the Nuremberg Rules were not well known to doctors. It would be difficult to read them as a code intended to regulate general clinical practice, rather than specifically concerning experimentation on human subjects, the specific context for which they were drawn up. While one can see reflections of part of the language of Rule 1 in later statements of practice and while it can be accepted that those who drafted later the BMA and the GMC guidance may well have drawn on the language of the Code, it cannot be maintained as a matter of language or substance that Rule 1 was an explicit statement of the right of every patient to consent to and hence to refuse any form of medical treatment. As Professor Nathanson recognised, the modern rule on consent is not unqualified: public health requirements may over-ride individual patient interests, for example.<sup>62</sup> The Nuremberg Code was unqualified because it dealt with a particular and limited context in which more or less absolute rules were appropriate.

**32.69** In contrast to these sources, ethical principles and rules may often be influenced by judicial decisions. Decisions declaratory of the common law are, in principle, not innovative, and may support the view that a professional response, in stating or re-stating current ethical requirements, is an expression of the pre-existing position. *Medical Ethics Today: Its Practice and Philosophy* (1993) stated (in the language of English law):

In many aspects of medicine, the legal and ethical requirements are separate and ethical guidance need make no reference to law. Consent, however, is an issue which binds the two since failure to seek patient consent is not only a moral failing but leaves the doctor liable in the crime or tort of battery or in the tort of negligence.<sup>63</sup>

In Scots law, the doctor might be liable to criminal proceedings for assault or open to a claim for damages for negligence.

**32.70** Some landmark decisions were relevant to the consideration of generally accepted standards of ethical conduct:

- In *Bolam v Friern Hospital Management Group* (1957) it was noted that the test of negligence in treatment of a patient had long been whether the doctor's practice conformed to that of a responsible body of opinion among practitioners skilled in the relevant field.<sup>64</sup>
- In Scotland, similar principles had been expressed in 1955 by Lord President Clyde in *Hunter v Hanley*. The test was said to be whether the doctor has been guilty of such failure as no doctor of ordinary skill would be guilty of if acting with ordinary care.<sup>65</sup>
- The legal standard for deciding whether adequate information had been given to the patient was held in *Sidaway v Board of Governors of the Bethlehem Royal Hospital* (1985) to be the same as in negligence.<sup>66</sup>

**32.71** It is possible that there had been a professional standard relating to explicit and informed consent prior to 1988 that was higher than the standard in negligence. However, Lord Scarman's comments in the *Sidaway* case, quoted in *Medical Ethics Today* (1993), suggest that that would have been difficult. Of the test in negligence, he said:

<sup>62</sup> Professor Nathanson's first report to the Inquiry [PEN.012.0330] at 0332

<sup>63</sup> British Medical Association, *Medical Ethics Today: Its Practice and Philosophy*, 1993, BMJ Publishing Group, London, page 3.

<sup>65</sup> *Hunter v Hanley* 1955 SC 200

<sup>66</sup> *Sidaway v Board of Governors of the Bethlehem Royal Hospital* [1985] AC 871

Ideally, the court should ask itself whether in the particular circumstances the risk was such that this particular patient would think it significant if he was told it existed. I would think that, as a matter of ethics, this is the test of the doctor's duty. The law, however, operates not in Utopia but in the world as it is: and such an inquiry would prove in practice to be frustrated by the subjectivity of its aim and purpose.<sup>67</sup>

**32.72** In *Medical Ethics Today: Its Practice and Philosophy* (1993), at page 11, it was commented:

Thus ideally, the doctor should inform the patient about any risks inherent in the treatment which might be particularly important to that patient as well as explaining the risks and benefits of alternatives and of non-treatment.<sup>68</sup>

**32.73** It is not unlikely that a doctor, also operating in the world as it is in treating a patient, might be as frustrated by the ideal question as is the law. One might think it necessary that a regulatory or advisory body stipulating that the clinician should ask 'whether in the particular circumstances the risk was such that this particular patient would think it significant if he was told it existed' should also provide guidance on how to approach the question and gather the information required for a rational analysis. The 1993 guidance attempted to do that, but that was after the material period for this Inquiry.

**32.74** The Inquiry was not provided with published evidence that there was a generally accepted rule of practice up to 1988, of sufficient specificity, that was more demanding than the test of negligence (namely, did the doctor's practice conform to that of a responsible body of opinion among UK practitioners skilled in the relevant field) and specifically a test requiring a doctor to treat a patient only on the basis of the patient's explicit and informed consent. On the best view of the publications and Professor Nathanson's evidence, the 1988, and then the 1993, publications were the first specifically to adopt that formulation.

**32.75** Professor Nathanson adopted the position that each of the BMA and the GMC 1988 publications represented the general comments on consent as reflecting long accepted practice, well understood within the profession. Though focussed on HIV infection, she considered it clear that paragraph 12 of *HIV Infection and Aids: the Ethical Considerations*, quoted above at paragraph 32.42, described the basis of treatment for all illnesses and not just HIV.<sup>69</sup>

**32.76** Professor Nathanson commented that the best practice standard in 1988 was that doctors only treated patients with their consent. Patients made the decisions and the doctor offered advice and guidance and might assist an individual in deciding between treatments but ultimately it was the patient who made the decision:

[I]t was quite clear to me from published information that we would expect that patients would be given information to make decisions for themselves, certainly about treatment.<sup>70</sup>

**32.77** In presenting her evidence, Professor Nathanson did not distinguish testing from treatment. The 1988 statement in the GMC publication *HIV Infection and Aids: the Ethical Considerations* reflected the Council's view that consent was required for treatment,

<sup>68</sup> Ibid page 11

<sup>69</sup> Professor Nathanson – Day 84, pages 25–26

<sup>70</sup> Ibid page 25

but spelled out specifically its view of the need for consent to investigative procedures. Professor Nathanson thought that the approach of the publication reflected more general changes in attitude among doctors during the 1980s. This led to discussion. Professor Nathanson said that it was a highly complicated issue. In the mid 1980s the BMA sought legal advice from counsel whether consent to treatment included consent for testing (specifically with regard to HIV testing). Counsel's opinion was explicit that treatment included testing, in that it was a necessary implied part of treatment.<sup>71</sup>

**32.78** Professor Nathanson commented in oral testimony:

We had expected that to be the case because you don't do testing if you are not thinking of doing something with that test result and you can't carry out treatment without having done testing, and they are so integrated that treatment is held, and I think in most of medical practice would be held, to include that process of seeing the patient, examining them, taking a history and so on, doing various tests and carrying out treatment and monitoring that treatment and modifying it, and that that is all-encompassed under that word "treatment".<sup>72</sup>

**32.79** So far as related to periods before 1988, the representation that the statements concerning consent published in 1988 were long-accepted practice became a focus for disagreement between Professor Nathanson and other experts. Having regard only to Professor Nathanson's evidence of the background circumstances in which the GMC came to adopt the guidance of 1988 relating to HIV testing, it would be difficult to accept the statements in the 1988 publications as an indication of a generally accepted standard of ethical conduct in, say, 1984, a significant year in the investigation of the prevalence of HTLV-III/HIV infection in the haemophilia population. Professor Nathanson considered that later publications such as *Medical Ethics Today: Its Practice and Philosophy* (1993) also expressed what was already accepted or established as proper ethical conduct by the time of publication.

**32.80** On the evidence available to the Inquiry, the formal documents published by the BMA and the GMC remain the best sources of evidence of when the process of development of thought crystallised into rules of general ethical practice, what those rules were, and how they were regarded by the medical profession, in the material period.

### **Testing for HIV and the communication of test results**

**32.81** As events were to prove, the risk of transmission of NANB Hepatitis/HCV was present before and continued after the AIDS period (broadly 1981 to 1985 in the case of coagulation disorder patients). However, there are questions as to whether AIDS was so significantly different from other viral diseases that the scientific and clinical response to it marked a step change in ethical practice that not only affected later ethical standards relating to hepatitis, but also innovated on previous accepted standards. If the answer to these questions is in the affirmative there is a further question as to whether one can infer from views expressed during and after the AIDS period what the direction of change in standards had been or was likely to have been in relation to NANB Hepatitis/HCV.

---

<sup>71</sup> While Professor Nathanson did not say so explicitly, it appears that this advice was sought separately from the advice referred to in paragraph 32.40.

<sup>72</sup> Professor Nathanson – Day 84, page 31

**32.82** As already noted, the statements of 1988 narrated that the guidance then set out reflected 'long accepted practice'. There is a temptation, to which those seeking to drive forward professional standards are perhaps irresistibly exposed, to make assertions to that effect. The response to an emerging problem such as AIDS may provide an opportunity for a wider and more general re-assessment of standards: anything that disturbs the equilibrium of a more or less static social group can open the way to radical change. Both factors are apparent in the 1988 documents.

**32.83** The impact of AIDS was swift and significant following the first reports in 1981. Dr Hay said 'the presentation itself was fairly dramatic and ... it was associated with death from the very beginning'.<sup>73</sup> Some patients with haemophilia died early in this period. In the mid-1980s an HIV test became available for use and it became apparent that 50% of UK patients with severe haemophilia were infected. There were patches of the UK (and in Scotland in particular) where the concentration of infection was lower.<sup>74</sup> However, under these circumstances, HIV/AIDS became the principal concern of both haemophilia clinicians and their patients. Dr Hay said:

This overshadowed hepatitis, which was considered benign and of little concern at the time to the extent that patients were not counselled to the same degree about non-A, non-B hepatitis as they had been in the immediately preceding period.<sup>75</sup>

**32.84** He also commented that:

The implications of a +ve HIV test could be perceived as a death sentence, led to loss of insurance, marriage breakdown, and even in some cases suicide.<sup>76</sup>

**32.85** Speaking about communication with patients, Dr Mark Winter stated that the culture of medicine 'was completely changed by AIDS'.<sup>77</sup> Many of the clinicians who lived through the period have also stressed that the arrival of HIV and AIDS was responsible for changing medical practice irrevocably. It is important to remember the effect of AIDS when examining the practices and decisions taken by clinicians during the reference period, and the suddenness with which they were confronted by this new disease. Even so, it was 1988 before the GMC responded with the publication of *HIV Infection and Aids: the Ethical Considerations*.

**32.86** The circumstances leading up to the publication of *HIV Infection and Aids: the Ethical Considerations* have been described in paragraph 32.40 above. HIV testing was distinguished from other conditions for which patients were tested. The question of consent to investigation first became prominent in the second half of 1984 when research assays were used to investigate the prevalence of HTLV-III/HIV in a broad range of cohorts including haemophilia patients, and then more generally in early to mid-1985 when the first diagnostic test for antibodies to the virus became available and the significance of the results began to be appreciated. It is not necessarily the case, however, that there would have been widespread appreciation of the issue throughout the medical profession.

---

<sup>76</sup> Ibid [PEN.018.1186] at 1212

<sup>77</sup> Dr Winter – Day 16, page 148

**32.87** Professor Nathanson emphasised the small number of AIDS cases that would have been seen by non-specialist medical professionals, even by 1986 and 1987 when the BMA committee on standards and ethics was considering the topic that resulted in the guidance of 1988.<sup>78</sup> The science on AIDS was at an early stage and still evolving. The majority of doctors in the UK had never seen a patient who was HIV-positive or who had AIDS. Many doctors might have known the symptoms: they would have known the theory but they may not have been completely up to date.

**32.88** There were specialists with intimate practical experience and knowledge of HIV. Infectious diseases doctors and haemophilia clinicians were among those who did see a disproportionate number of patients with HIV and Professor Nathanson's views on the ethical requirements for testing have particular relevance in the context of the management of their patients.

**32.89** Considerable debate developed over whether those for whom a test for HIV might be considered clinically relevant needed to be asked for consent to the test. In the early days of testing many doctors believed that HTLV-III antibody tests could and should be carried out without consent and that taking blood for the test at the same time as other routine medical tests would mean that 'necessarily implied consent' had been given. In her report Professor Nathanson commented:

If patients are aware that they are routinely and regularly being tested for a panel of infections, for example blood borne viruses, it was certainly arguable that testing for hepatitis C was no different from other such routine tests. Many would then have considered testing for HIV in the same way, given that there was at the beginning of the period considerable doubt as to its nature, transmissibility and relevance to the newly emerging medical condition of acquired immune deficiency.<sup>79</sup>

**32.90** Professor Nathanson commented on what specific consent requires:

The General Medical Council's advice is that consent requires that the patient understands what you are doing, why you are doing it, what the consequences are and what you will do about it. It's a counsel of perfection. How much we all, as individual patients, remember about what we are told is always variable and arguable, but certainly all that information should be made available and should be offered to the patient and there should be no limit .... You should be prepared to tell the patient everything.<sup>80</sup>

**32.91** She also described what was meant by 'necessarily implied consent':

Necessarily implied consent really means that the patient is doing something which makes it clear that nobody would argue that they are doing anything other than consenting to that test. The interesting issue around this was, for example, if you go in to see a doctor and the doctor says, "I want to take some blood tests" and you roll up your sleeve and hold your arm out to have the blood taken, then you are clearly necessarily implying [consent] to having a needle stuck in your arm and some blood taken.<sup>81</sup>

---

<sup>78</sup> Professor Nathanson – Day 37, pages 33–35

<sup>79</sup> Professor Nathanson's first report to the Inquiry [PEN.012.0330] at 0336

<sup>80</sup> Professor Nathanson – Day 37, pages 86–87

<sup>81</sup> Ibid page 90

**32.92** In relation to HTLV-III/HIV testing, Professor Nathanson's own view was unequivocal. Put simply, testing required specific consent. The concept of necessarily implied consent could not be held to apply to testing for this virus. In principle, implied consent could only be held to apply to procedures in hand and not to new procedures.

**32.93** How that related to the general clinical environment can perhaps best be understood in the light of Professor Nathanson's observations on the steps she considered it was necessary for her to take as head of ethics at the BMA:

[O]ne of the first things I did in April 1987 – when I took over as head of ethics, I was involved ... in developing a series of videos for doctors, which Wellcome actually sponsored, and we got pharmaceutical reps to take it around the country into every GPs surgery: three films on testing for HIV, including getting consent, upon all the issues around control of blood-borne infections and particularly the kind of advice that they could give to families. We were developing a lot of advice to individuals, but also schools and churches were contacting the BMA for advice on the risks of cross-infection and there was just a lack of good solid, simple consolidated information on the science for the non-experts and the people who might be seeing a case for the first time.<sup>82</sup>

**32.94** The observations are significant. They reflect the lack of previous advice from regulatory, advisory and other official sources; they underline Professor Nathanson's own role among those driving developments in ethical practice; they provide a reference date for the provision of effective advice about HIV to the wider profession; they define the background to the publication of the BMA's advice in 1988; and they express the lack of relevant knowledge of the disease among the medical profession generally. Finally, they reflect the contemporaneous understanding among those leading the development of professional thought, that guidance on questions such as consent was required.

**32.95** At this time, the BMA was moving towards the provision of explicit advice generally. Professor Nathanson commented, specifically in relation to testing, but with wider relevance:

Throughout medicine, consent was obtained for most things that are done. The question was always about whether a test was something that was so much inherently part of the treatment, including the diagnosis, of that patient that it was covered by necessarily implied consent or whether it was something that was less common, less usual, less standard and therefore needed to be explicitly taken out of that and to be absolutely explicitly the subject of consent. We were in the process of moving towards being as explicit as possible about everything that is done and that included the HIV test, and many people who were content with the concept of necessarily implied consent for many other tests were not content for it on HIV, for example, because of other reasons, not necessarily purely medical ones but because of the consequences of the test result.<sup>83</sup>

---

<sup>82</sup> Professor Nathanson – Day 37, pages 34–35

<sup>83</sup> Professor Nathanson – Day 37, pages 154–55. The observation was made in the context of questions related to testing stored samples, but had general significance.

**32.96** Pre-test counselling for HIV raised specific issues. Professor Nathanson explained:

Pre-test counselling is a little different. When you are testing for some conditions, what you would then do is say, “In this one area of testing there are some very specific things which you need to understand about the limits of the test or the implications of the test”. With HIV we really started to discuss pre-test counselling in a very formal basis, not necessarily because of the diagnosis clinically but predominantly because of the social and economic consequences. So the inability, for example, to get life insurance, mortgages, those sorts of things, for patients. And particularly early on, when we didn’t know whether people would survive or not ....<sup>84</sup>

**32.97** The 1988 guidance highlighted the specific non-medical consequences of a positive result, such as social stigma or employment and financial consequences. Professor Nathanson noted that such consequences may emerge and develop over time; they may not be recognised when a procedure is first introduced, although HIV did quickly come to have obvious and serious non-medical consequences, essentially financial and social.

**32.98** By 1988 it was also recognised that consent was particularly important in the case of testing for HIV infection because of the possible serious social and financial consequences which might ensue for the patient from the mere fact of having been tested for the condition, irrespective of the result of that test.

**32.99** Professor Nathanson explained that the modern approach is to offer full information to a patient about the results of a test but not to oblige them to receive that information if they indicate that they do not want to know.<sup>85</sup> Where there are health benefits to a patient from knowing their diagnosis or where a third party (such as a sexual partner) could benefit from knowing about the diagnosis, a clinician can and should press harder to encourage a patient to agree to be told of their results. However, she said that she would be reluctant to ‘force’ a patient to know the results of any given test, but that a medical practitioner should use appropriate communication skills to assist the patient in understanding the implications and to agree a plan of action. She explained that in some circumstances a clinician might increase the ‘amount of weight’ that they put in to persuading a patient about the benefits to them of receiving results.<sup>86</sup> She said that most clinicians in these circumstances found that patients: ‘don’t ever say they don’t want to know something when you are telling them that there is a benefit to them in knowing’.<sup>87</sup> She acknowledged that it is ‘extraordinarily difficult’ for a doctor to approach the question of positive test results without signalling to the patient that they have bad news to impart.

**32.100** Professor Nathanson explained that it was essential for the doctor to let the patient know that s/he has information about him, that tests had been done, and that results were available, and to ask whether the patient wanted the results. She said that it became easier to communicate results as time went on because coagulation disorder patients, who had access to the literature, and were a well-informed group, knew what was happening and realised that ‘more and more of their number were being found to be positive’.<sup>88</sup>

<sup>84</sup> Professor Nathanson – Day 37, pages 87–88

<sup>85</sup> Ibid pages 121–127 and 155

<sup>86</sup> Ibid page 124

<sup>87</sup> Professor Nathanson – Day 37, page 125

<sup>88</sup> Ibid pages 126–127

**32.101** The GMC guidance in 1988 stated that:

The Council takes the view that any doctor who discovers that a patient is HIV positive or suffering from AIDS has a duty to discuss these matters fully with the patient.<sup>89</sup>

**32.102** In relation to the Council's view, Professor Nathanson said:

I think that that's the first time that the GMC was as explicit as this and I'm not aware in any of their earlier publications that they had been as explicit, in any condition, about informing the patient. It had been implicit in a great deal of what they have said but not explicit. So certainly at that time, in 1988, it would have been clear to all doctors on the basis that the GMC advice goes literally to all doctors on the register.

It didn't go into any more detail about it but I think that the duty to discuss these matters fully is pretty explicit and would make it clear that you had to discuss all the relevant matters.<sup>90</sup>

**32.103** She contrasted the position adopted with what had generally been the situation previously. The Council's published view of the doctor's duty to discuss with the patient, in her view:

[R]ecognised, of course, that that hadn't been the case in the past. If all doctors had always told all patients the full details, fully informed, fully discussed, then they wouldn't have needed to make the statement or the statement would have been made something like, "As with all other conditions," or something of this form.

The fact that they felt it necessary showed that they recognised that doctors didn't always tell patients everything or fully discuss and that this was essential. And certainly in the late 1970s, it would have been extremely rare to tell patients everything but this was part of this evolution towards patient-centred care that I described earlier, that this was becoming a commoner practice anyway.<sup>91</sup>

**32.104** That period, in Scotland and indeed generally, was a time of great change in coagulation disorder therapy. HTLV-III/HIV infection had been identified in haemophilia patients and widely publicised, causing great disturbance. The majority, if not all, of haemophilia patients in Scotland (at least in the two major regions with centres in Glasgow and Edinburgh) had been tested using stored samples from routine management of their primary condition. Virus inactivation processes in the manufacture of Factor VIII concentrates were quickly devised at the end of 1984 and implemented from January 1985, changing the context in which risks associated with continuing therapy might be discussed: patients newly diagnosed with Haemophilia A after January 1985 were not exposed to risk of transmission of HIV by SNBTS concentrates. The emphasis was changing from testing (in many cases a past event) to repeat testing of established patients and the communication to them of test results. While Professor Nathanson's evidence was uncompromising that patient consent to testing was necessary, in the short period when risk was at its highest (roughly from 1982 to the end of 1984) the context for providing information and advice and seeking consent to investigation was changing rapidly. Her own actions on appointment as Head of Ethics in April 1987 were clearly innovative.

<sup>89</sup> *HIV Infection and AIDS: the Ethical Considerations*, General Medical Council, May 1988 [PEN.016.1165] at 1169

<sup>90</sup> Professor Nathanson – Day 37, page 113

<sup>91</sup> Professor Nathanson – Day 37, page 114

**32.105** In the circumstances, it is difficult to infer from Professor Nathanson's evidence alone that there were generally accepted ethical standards relating to the management of patients actually or potentially exposed to risk of HIV infection in the critical, short, period between 1982 and the publication of the 1988 guidance.

**32.106** Other evidence on this topic indicated that there were variations in approach. Dr Winter said that in 1984 and 1985 the way that results of HIV tests were communicated to patients varied very widely. At his Centre he personally met with each of his patients to give them news of the outcome of tests.

**32.107** In a paper produced in response to Professor Nathanson's first report, Dr Hay commented on consent to testing and the communication of test results.<sup>92</sup> He said that paragraph 4 of the 1988 GMC Guidance *HIV Infection and Aids: the Ethical Considerations*, which dealt with obtaining consent to testing, reflected normal practice for HIV infection only from the late 1980s onwards. He explained that most haemophilia centres counselled patients at the time of HIV testing, from 1985, and then communicated the results in face-to-face interviews. Much of what the patients were told in those interviews turned out to be incorrect but it was the best information or opinion available at the time. Some centres took a different approach. He said that in Liverpool and Manchester HIV results were communicated to the patient by letter. He commented:

This practice was widely considered reprehensible, even at the time, and left an understandable and enduring legacy of anger and bitterness in the affected families. There was no agreed policy about this at the time, however. Counselling for HIV testing became more formalised and universal in the later eighties.<sup>93</sup>

**32.108** In that respect, the management of patients exposed or potentially exposed to risk of HIV infection was not distinguished from practice in relation to viral infection generally. It appears to be clear that Professor Nathanson's observations relating to the doctor's duty to discuss HIV with patients were equally applicable to the wider context. There was no settled ethical standard relating to NANB Hepatitis, for example, available to the BMA or the GMC as a model or point of reference for the development of standards specific to HIV.

### **Testing for NANB Hepatitis/HCV and the communication of test results**

**32.109** The evidence of Dr Hay and Professor Nathanson in respect of testing for NANB Hepatitis/HCV and the provision of information to patients is recounted below. It will become apparent that there were some differences between them.

#### *Testing for NANB Hepatitis/Hepatitis C*

##### **Dr Hay**

**32.110** So far as haemophilia and other coagulation disorder patients are concerned, Dr Hay's approach to HCV testing and the provision of information did not vary according to the therapeutic products that had been administered, though he commented on the different levels of risk to which those receiving large-pool products were exposed in comparison with those who had received single donor products, and transfusion patients.

---

<sup>92</sup> Dr Hay's commentary on Professor Nathanson's first report to the Inquiry [PEN.018.1349]

<sup>93</sup> Ibid [PEN.018.1349] at 1353

**32.111** Dr Hay's assessment of the risk of HCV transmission by way of large-pool blood products was clear: 'Patients treated with pooled blood products prior to the introduction of viral attenuation in 1985–87, will have been infected with hepatitis C'.<sup>94</sup> With donor pools for manufacturing concentrates containing 20,000–50,000 donations in the commercial sector, even with a low prevalence of infection in the donor population,<sup>95</sup> inevitably there would be a number of infected donations in each plasma pool. He reiterated the point in oral testimony: 'all the concentrates prior to viral attenuation would transmit Hepatitis C'.<sup>96</sup> Given the large number of donor units in each pool,<sup>97</sup> there was realistically no difference, in terms of HCV-infectivity, between different product brands sourced from the UK, mainland Europe or the USA or between large-pool products based on paid or voluntary donations.<sup>98</sup>

**32.112** By contrast, the risk of HCV transmission for transfusion patients (or haemophilia patients using cryoprecipitate) was considerably lower. Dr Hay described a methodology for estimating the risk of transmission of HCV from single-donor blood products:

The risk of transmission of hepatitis C from ... single-donor blood products depends on the number of units transfused, the year in which the donations were collected and the prevalence of hepatitis C in the relevant donor population at that time .... The prevalence was considered relatively high in the USA and in Southern Europe but relatively low in Northern Europe: the UK, France and Holland.<sup>99</sup>

**32.113** As applied to the UK around 1982–84, Dr Hay estimated the risk as 'probably significantly in excess of 0.4% .... This would place the risk during 1983-4 at between 0.6% and 1% per unit of single-donor blood product transfused, say 0.75%'.<sup>100</sup> On this assessment of risk, many coagulation disorder patients would have been infected with HCV before they were given concentrate, especially those with severe haemophilia who were regularly treated with cryoprecipitate.<sup>101</sup>

**32.114** The situation changed from around the mid-1980s with the introduction of donor self-exclusion for at-risk groups and HIV testing of blood donated for clinical use.<sup>102</sup> Some evidence suggested an approximately tenfold reduction in the risk of post-transfusion HCV transmission as a result. Although Dr Hay observed that this would not make much difference to the risk from concentrates derived from large donor pool plasma, for the reasons already given, the risk of transmission from single donor units such as cryoprecipitate or red cells was considerably reduced.<sup>103</sup>

<sup>94</sup> Dr Hay's statement on communication to patients [PEN.018.1186] at 1199. See Chapter 15, *Knowledge of Viral Hepatitis 2 – 1975–1985*, paragraph 15.122. Dr Craske reported in September 1983 that the risk of contacting NANBH following first exposure to large pool concentrates was 100%.

<sup>95</sup> The prevalence of Hepatitis C in the donor population during the 1970s and early 1980s was not known with certainty but was subsequently estimated to have been approximately 0.4–1.0%. Pool volumes of the order mentioned were typical of commercial production. NHS pool volumes were considerably lower but still large enough for the same general conclusion to apply.

<sup>96</sup> Dr Hay – Day 83, page 85. Whilst effective in eliminating HIV, early attempts at viral inactivation were not completely effective in eliminating the risk of Hepatitis C transmission.

<sup>97</sup> Dr Hay – Day 83, page 86

<sup>98</sup> Dr Hay's statement on communication to patients [PEN.018.1186] at 1200; Fletcher ML et al, 'Non-A non-B Hepatitis after transfusion of factor VIII in infrequently treated patients', *British Medical Journal*, 1983; 287:1754–57 [LIT.001.0239]

<sup>99</sup> Dr Hay's statement on communication to patients [PEN.018.1186] at 1200

<sup>100</sup> *Ibid* at 1204

<sup>101</sup> Dr Hay – Day 83, pages 88–89

<sup>102</sup> Dr Hay's statement on communication to patients [PEN.018.1186] at 1192

<sup>103</sup> Dr Hay – Day 83, page 82

**32.115** The mid-1980s marked the point at which there was growing appreciation of the severity of the risks associated with NANB Hepatitis. For transfusion patients that was offset to some extent by the reduced risk of transmission but the risk of transmission was not materially reduced for those receiving large-pool concentrates. For all patients, the risks of progressive liver disease became more fully understood in about 1991, when anti-HCV testing was introduced, and there was a further step change in understanding in 1995 when the link between HCV and hepatocellular carcinoma was established.

**32.116** Dr Hay said that from the mid-1970s to the early 1980s very little would have been said to patients about NANB Hepatitis because little was known about the condition and because, insofar as it was understood, it was not thought to be a serious clinical concern.<sup>104</sup>

**32.117** Although local practices varied, in Dr Hay's experience haemophilia centres had started to check liver function tests regularly in about 1980.<sup>105</sup> Patients may have had 'persistently' or 'intermittently' abnormal liver function test results. At this time, if a patient had at least two abnormal liver function tests over at least six months, the condition was described as 'chronic'. Dr Hay said:

From the late 1970s onwards, most regularly reviewed patients would have had liver function tests conducted and I would expect most of those affected to have been told that they had non-A, non-B hepatitis but that it was probably nothing to worry about.<sup>106</sup>

**32.118** Advice on NANB Hepatitis in the mid-1980s was similar to the advice given in the previous period. Dr Hay commented that in the mid-1980s patients would have been told that NANB Hepatitis was, comparatively at least, nothing much to worry about at around the same time as they were being informed of life-threatening HIV in the blood supply. The risk of HIV/AIDS had come to dominate thinking.

**32.119** Dr Hay said in oral evidence that he provided counselling for patients prior to testing for HCV. In his haemophilia centre, the staff informed patients they were testing them for Hepatitis C, discussed the result face-to-face with them when available and wrote to their GP and documented the discussion.<sup>107</sup>

**32.120** The patient would have the opportunity to refuse the test. Although some patients did not want to be tested for HIV, Dr Hay could not recall anyone refusing an HCV test. Clinicians would have had an idea of the likely results when patients were tested for HCV for the first time on the basis of a history of abnormal liver function tests. Dr Hay said that he would discuss the implications of a positive HCV test result and, if the patient had a history of abnormal liver function tests, he would have prepared them to expect a positive result.<sup>108</sup> He explained:

[I]f I was testing for hepatitis C, I would tell the patient that I was going to conduct the test. I would take the opportunity to talk to them again about

---

<sup>104</sup> Dr Hay's evidence reflects his experience, and in particular the Sheffield studies of NANBH. In other areas, such as south east Scotland, until a test for HCV was available, people found to have abnormal liver function test results would not often have a diagnosis of NANBH on that basis alone: see Chapter 16, *Knowledge of Viral Hepatitis 3 – 1986 Onwards*, paragraph 16.32. Clinical jaundice was a required diagnostic feature.

<sup>105</sup> Dr Hay – Day 83, page 104

<sup>106</sup> Dr Hay's statement on communication to patients [PEN.018.1186] at 1208

<sup>107</sup> Dr Hay went on to comment (Day 83, page 123) that what he did went beyond what a Hepatologist would have done for a patient, then and now.

<sup>108</sup> Dr Hay – Day 83, page 121

hepatitis C. I would have expected that conversation would already have taken place about liver disease. I would not take written consent for the test.<sup>109</sup>

**32.121** Dr Hay compared the national guidelines for testing patients for HIV.<sup>110</sup> The circumstances surrounding HIV testing required a much longer and more involved conversation, having regard to the wider consequences for the patient, and patients should have been given the opportunity to go away and think about it before providing a blood sample for a test.<sup>111</sup>

**32.122** The implications of a positive HCV test result were, and are, quite different from those associated with a positive test for HIV and the pre-test conversation would be different in each case. Dr Hay considered that pre-test counselling for HIV was not an appropriate model or point of useful comparison for HCV testing. The discussion with a patient prior to an HCV test would typically take five minutes, unless the patient had a great many questions.<sup>112</sup> Now, the discussion tends to be about the side-effects and relative merits of treatment. That would not have been part of the subject matter prior to the introduction of Interferon in the mid 1990s. Dr Hay was of the view that haemophilia clinicians talked more about HCV tests with their patients than hepatologists would, in part because of their experience with HIV testing. He thought this may have created an expectation of what ‘counselling’ entails in that patient group different to that in the general population. He thought that, when thinking of the HCV test, haemophilia patients tended to draw a parallel with their experience of counselling related to HIV and respond critically, in comparison, to the discussion that took place prior to HCV testing. In reality, according to Dr Hay, there were probably never any guidelines on taking consent for Hepatitis C testing.<sup>113</sup>

**32.123** Dr Hay commented on the differences in approach adopted by hepatologists and haemophilia practitioners respectively.<sup>114</sup> In his view, a hepatologist was likely to tell a patient more assertively that they intended to test for hepatitis viruses because the patient’s liver function was abnormal. A haemophilia clinician was more likely to tell a patient they thought a test for HCV was appropriate since it was a probable cause of their signs of liver disease. He acknowledged that there was a distinction between the approaches, but he did not agree that the approach of haemophilia practitioners involved asking for the patient’s consent to test. He thought it was more likely to be down to the style of the individual doctor involved.<sup>115</sup>

**32.124** He considered that haemophilia clinicians were obliged to test everyone for HCV and would be open to criticism if they did not. If a patient had said ‘no’ to a test, there would have been a further conversation and in Dr Hay’s view consent would have been obtained by persuasion. In reality, he thought that some of his colleagues may have tested for HCV without informing the patient specifically that they were testing for the virus.<sup>116</sup> They may have regarded it as just another liver function test and with this came the view that there was no need to discuss it or to request consent.<sup>117</sup>

<sup>117</sup> Minutes of AIDS Group of Haemophilia Center Directors, 12 February 1990 [LOT.003.4450] at 4453. Professor Bloom commented that he did not see why consent was required for a HCV test as it was just another liver function test.

## Professor Nathanson

**32.125** Professor Nathanson's view was that the best practice standard of 1988, that a patient give consent to any investigation and treatment proposed by the doctor, still applied in the 1990s. In her view the best practice in the early 1990s, when an HCV test became available, would have been for the patient to be told they were being tested for Hepatitis C before a sample of blood was taken for that purpose. She said:

So it was quite clear to me from published information that we would expect that patients would be given information to make decisions for themselves, certainly about treatment. The question that always comes then is whether testing is counted as treatment, and the best practice advice, again from the 1980s, is very much that it does, that testing is the beginning of medical treatment. It is the precursor to actually offering a treatment, whether that treatment is surgery or drugs or whatever else it is, that you have to first establish a diagnosis and that testing is part of that process. So you would expect the patient to consent to that test.<sup>118</sup>

**32.126** However, she said that much would depend on the individual patient. For all but new patients introduced to testing for the first time the history of prior testing was an important factor. If the patient had already been informed on the basis of previous monitoring that it was likely that they had NANB Hepatitis, the HCV test became in effect a confirmatory test for a specific virus. Professor Nathanson explained that the preference in those circumstances would be for patients to have been told specifically that they were being tested for one of the viruses that appeared to cause NANB Hepatitis:

That didn't mean you went back to first principles every time you did a repeat test; it just meant that the patients already knew that they had non-A non-B Hepatitis. It might simply have been, "We now have a test for a particular type of non-A non-B and we are going to carry out that test for you ...."<sup>119</sup>

**32.127** However, she would expect that at that time there would be some clinicians who would not have given patients that explanation.<sup>120</sup> Some doctors embraced the new ethical imperatives more quickly than others.

**32.128** Telling a patient that they were being tested for HCV would have involved counselling the patient about the test before it was performed, a provision that left considerable scope for flexibility in dealing with individual patients. She explained that counselling prior to HCV testing was a means of giving patients the information they needed to help them make a choice on whether to have the test or not.

**32.129** Professor Nathanson was asked about the information relating to HCV that should have been given to patients before a test was carried out after 1997. She explained that much depended on the specialist carrying out the test. From 1997, a liver specialist seeing a patient on referral from another clinician would not have to explain to a patient that they had liver function problems. The aim of the liver specialist was to carry out a series of tests to ascertain what could be done to determine the cause of and to treat the abnormalities for which the patient had been referred. A clinician seeing a patient earlier in the process, when it was unclear what their medical condition was, would have

---

<sup>118</sup> Professor Nathanson – Day 84, pages 25–26

<sup>119</sup> Ibid page 35

<sup>120</sup> Ibid pages 56–57

a different approach and would discuss with the patient the need to have their liver function examined. Much of the counselling would have been done before the patient was referred to the liver specialist.<sup>121</sup>

**32.130** Professor Nathanson said that, in comparison with pre-test counselling for HIV, she would expect pre-test counselling related to HCV to be relatively brief for most patients. Some patients would require a longer time if they found the diagnosis more difficult to accept. She would expect patients to be told it was a kind of hepatitis that had a long natural history and that it could be treated. The treatment could be unpleasant but it could be successful. If the patient's HCV test proved to be positive, it would be advisable to have further tests and almost certainly treatment would be offered.

**32.131** She would not expect there to have been much of a discussion of non-medical implications unless the testing doctor was aware of something specific for a particular patient. If a patient was a healthcare worker, for example, there would be particular concerns regarding the possible risk of transmitting the virus through their work. She was uncertain about advice to patients regarding sexual transmission as her understanding was that the evidence showed that HCV was not readily transmitted that way. The very limited evidence that it could be transmitted could be mentioned to the patient so that they would have the ability to protect their partner from any risk of transmission.

### *Communication of results*

#### **Dr Hay**

**32.132** As detailed in paragraph 32.116 above, from the mid-1970s to the early 1980s very little would have been said to patients about NANB Hepatitis. The general message to a patient diagnosed with NANB Hepatitis would have been reassuring. In his report Dr Hay summarised the position relating to NANB hepatitis at this stage:

In the late 1970s and early 1980s patients should have been told what was known about this type of hepatitis at that time. This would include:-

- a. Patients were generally asymptomatic
- b. That it was benign and non-progressive
- c. There was no test [for the condition]
- d. It was thought not to be readily transmissible
- e. There was no treatment at that time
- f. Patients should minimise alcohol intake.<sup>122</sup>

**32.133** As noted above, however, understanding of the natural history and severity of NANB Hepatitis had developed by the mid 1980s and the information available to clinicians, and therefore their patients, had improved. Dr Hay set out what haemophilia patients infected with NANB Hepatitis ought to have been told in this period:

In the mid 1980s most affected patients will have been told:-

- a. That they had non-A, non-B hepatitis,
- b. But since hepatitis was still considered non-progressive they would have been told that it was benign and non-progressive in most patients

---

<sup>121</sup> Ibid pages 34–35

<sup>122</sup> Dr Hay's statement on communication to patients [PEN.018.1186] at 1208

- c. That a minority, perhaps 20%, developed cirrhosis eventually
- d. That it was generally asymptomatic.
- e. That it was slowly progressive if it did progress
- f. That there was no test or treatment
- g. But we needed to monitor the liver disease systematically
- h. That they should minimise alcohol intake<sup>123</sup>

**32.134** Most patients received their first HCV test result in 1992 or 1993, shortly after tests became available.<sup>124</sup> Dr Hay explained that many patients had gained the false impression that they *contracted* HCV in 1992 or 1993 because that was the date of their first specific positive HCV test. In fact, as discussed above, clinicians had been aware of NANB Hepatitis for some years through routine monitoring of liver function tests. Dr Hay believed that patients with intermittent or persistently abnormal liver function tests should already have had that discussed with them and been given a diagnosis of NANB Hepatitis, although they may have forgotten that earlier diagnosis. Whether or not a clinician had previously told a patient that they were infected with NANB Hepatitis, and whether or not the patient remembered any such conversation, because of a history of abnormal liver function tests<sup>125</sup> it was assumed by clinicians that these patients had hepatitis and the newly developed HCV test in 1992 acted as a confirmatory test.<sup>126</sup>

**32.135** Dr Hay said that from the early 1990s clinicians were seeing more severe liver disease in HCV-positive patients. This was particularly so in patients co-infected with HIV since HCV progresses more rapidly in an immunosuppressed patient. Conversations about liver disease became more frequent and adopted a higher profile. Dr Hay summarised what patients were being told by the mid-1990s:

- a. That the condition was benign and non-progressive in most patients
- b. That there was eventual progression to cirrhosis in up to 30% of patients
- c. That HIV was a co-factor for hepatitis C progression as was alcohol
- d. That there was a small risk of liver cancer
- e. That there was treatment available with interferon but the treatment lasted six months and response-rate was only 25%
- f. That we needed to monitor the liver disease systematically<sup>127</sup>

**32.136** The background understanding against which to consider Dr Hay's evidence of practice in relation to the provision of information to patients differed as between coagulation disorder patients treated with concentrates and cryoprecipitate users and transfusion recipients of blood components. Notwithstanding the differences in risk, Dr Hay did not describe differences in approach to patients depending on whether they had received low or high risk therapy. It appears that if the circumstances indicated the need for an HCV test the same approach was adopted.

<sup>123</sup> Ibid at 1211

<sup>124</sup> Dr Hay explained that a small number of patients, typically those with mild haemophilia who are treated infrequently, may have been tested some time after 1992–93. In general, he felt that 'no harm will have come from this delay in diagnosis, because the rate of progression of hepatitis C is slow' and because early treatment had a low success rate. Dr Hay's statement on communication to patients [PEN.018.1186] at 1199

<sup>125</sup> Dr Hay remarked in oral evidence that some of these results could be due to alcohol consumption or obesity as in the general population, but because of the patient profile it was assumed abnormal LFTs were attributable to HCV. Some patients who tested positively for anti-HCV had normal liver function tests.

<sup>126</sup> Dr Hay – Day 83, pages 83–84

<sup>127</sup> Dr Hay's statement on communication to patients [PEN.018.1186] at 1213

**32.137** Developments in the 1990s also led to a change in the advice given to patients about the risks of sexual transmission of HCV. Dr Hay explained that, until then, nothing was said to patients about the risks of sexual transmission as, without a specific test for the disease, very little was known about the possibility of sexual transmission. Clinicians were not advising patients to use barrier contraception unless they were HIV-positive.<sup>128</sup> The advice to patients in this regard did not change until a test for HCV infection became available. It then became apparent that there was a small risk of sexual transmission and the partners of HCV-positive patients were offered tests.

**32.138** The mid-1990s also saw the introduction of therapeutic treatment for HCV infection, with Interferon available from 1995–96, and this became an important part of discussions with patients. The response rate to treatment at that time was low (early literature suggested a possible 25% response rate but a lower response rate of 10% was actually experienced by clinicians). Many patients were, and continue to be, put off by side-effects of Interferon treatment, which can be particularly unpleasant and debilitating, and many patients still refuse treatment altogether. Discussions about Interferon were often delayed for patients co-infected with HIV; partly because their response rate was even lower, partly because HIV was a sufficient burden for them to carry and partly because the clinicians were waiting for improvements in treatment. In contemporary practice, all patients are offered anti-HCV treatment. Current combination therapy is much more effective than the treatment used in the late 1990s.

### Professor Nathanson

**32.139** Professor Nathanson said that, during the period between 1991 and 2000 the correct way of communicating results of a test for HCV was essentially the same as it is today. However, while the theoretical approach was the same, it had to be recognised that medical practice and ethics were still evolving from the paternalistic basis of earlier in the twentieth century to the patient-centred model embraced today. Doctors were increasingly expected to conform to best practice, but adapted to this at different rates, not always related to their own age.<sup>129</sup>

**32.140** She also explained that it was important to recognise that in the 1980s there was great uncertainty throughout the medical profession about what a diagnosis of infection with NANB Hepatitis/HCV meant. There was a slow emergence of understanding of the disease and the very long natural history of the illness. In the early period of making a diagnosis of NANB Hepatitis/HCV this natural history was still emerging and uncertain. She explained that while doctors are used to dealing with uncertainty, including risks, many patients and relatives find that very difficult.<sup>130</sup>

**32.141** Professor Nathanson and Dr Hay had a common position relating to the patient's response to information. Dr Hay noted that some patients later denied that the conversations he described as taking place in the 1970s and early 1980s occurred. There might be no physical record detailing the conversations that did happen: he said that '[m]any of these conversations will have been forgotten and may not have been documented'.<sup>131</sup> He stated that most counselling of patients in the early 1980s was completely dominated by HIV. In addition, in the case of HCV, up to 40 years may have passed from the time of the

---

<sup>128</sup> Dr Hay – Day 83, page 118

<sup>129</sup> Professor Nathanson's supplementary statement [PEN.018.0419] at 0422

<sup>130</sup> Ibid [PEN.018.0419] at 0422–23

<sup>131</sup> Dr Hay's statement on communication to patients [PEN.018.1186] at 1208

original diagnosis of NANB Hepatitis to clinically significant manifestation of the disease. It is doubtful that, in the late 1970s and early 1980s at least, a treating doctor would have reminded their patient of their NANB Hepatitis diagnosis at every appointment in the intervening period. By way of contrast, Dr Hay told the Inquiry he now discusses his patients' liver function tests with them at every meeting and reminds them of the date of their next ultrasound.<sup>132</sup>

**32.142** In his report, in discussing what he considered to be a vital distinction between pre-test counselling for HCV as compared to the equivalent process before testing for HIV, Dr Hay noted:

Some patients have complained, many years after the event, that they were tested "without their permission". In some cases they may, indeed, have been tested without being specifically informed and in other cases it is documented that they were informed both that they were being tested and of the result. The idea that a hepatitis C test should engender prolonged pre-test counselling derives from the practice adopted after 1985 by most centres of counselling prior to HIV testing. The implications of a +ve HIV test could be perceived as a death sentence, led to loss of insurance, marriage breakdown, and even in some cases suicide. There is no comparison between this and hepatitis C testing. For that reason, there has never been a specific consent process attached to hepatitis C testing even though it would be normal practice to inform the patient that they were being tested and to inform them of the result.<sup>133</sup>

**32.143** In the mid-1980s, AIDS overshadowed hepatitis. He said of his patients that:

If they were counselled about hepatitis in the context of a consultation also about AIDS they would often "deny" hepatitis C and deny that it had been discussed. Denial is a common psychological defence mechanism. I have found that patients commonly deny that they have been counselled about hepatitis C even when such counselling has been documented in the notes.<sup>134</sup>

**32.144** In the mid-1980s clinicians telling patients that NANB Hepatitis was, comparatively at least, nothing much to worry about at around the same time as they were being informed of life-threatening HIV in the blood supply may well have contributed to the phenomenon of patients forgetting their initial diagnoses with NANB Hepatitis, particularly for those co-infected with HCV and HIV. HIV would have assumed much greater importance compared to a disease about which little was known and which was suspected of being relatively benign. In the course of a single consultation a number of things would be discussed: a patient's haemophilia, the frequency and location of bleeds, as well as their hepatitis and HIV. If they had HIV, that would be the issue with immediate importance. Discussion was dominated by HIV – a condition that rapidly led to illness and then death – for which there was no test or treatment.<sup>135</sup>

**32.145** Dr Hay added that these conversations about NANB Hepatitis would have been short and not particularly memorable. Patients would have been advised that NANB

---

<sup>134</sup> Ibid [PEN.018.1186] at 1209

<sup>135</sup> Ibid

Hepatitis was not thought to be particularly infectious and that, unless they also had HIV, condoms were not required. Spouses were generally not tested at that time.<sup>136</sup> This advice differs slightly from the advice given to patients in the late 1970s to early 1980s.<sup>137</sup> The advice to patients in that earlier period of time would have been ‘relatively reassuring’.<sup>138</sup> Dr Hay added that, even if clinicians quoted the 20% risk figure, this may well have been regarded as reassuring; again, he knew of patients who could not remember these conversations at all. Even with discussion of a risk of progression to serious liver disease, he thought that many patients left with the impression that they would not themselves be amongst those who progressed to that stage.<sup>139</sup>

### ***Dr Hay’s Commentary on Professor Nathanson’s second report***

**32.146** Dr Hay was invited by the Inquiry to comment on Professor Nathanson’s report on practice relating to HCV management (discussed above) and he produced a commentary on it.<sup>140</sup> In general terms, he noted that, of the four publications she referred to, two, the GMC *Guidance on Serious Communicable Diseases* (1997) and *Consent: patients and doctors making decisions together* (2008) were not contemporaneous with the period under discussion. None of the four was specific to HCV and only the 1997 *Guidance* made a (single) mention of the disease.<sup>141</sup> Dr Hay said that there had never been any specific advice from the GMC, the BMA, or any other body relative to consent or counselling for HCV testing.

**32.147** He observed that, although Professor Nathanson acknowledged that the approach to consent to testing would be tempered by knowledge of HCV at any particular point in time, she did not develop this point in her report and offered no opinion on the way in which changing states of knowledge would have affected consent at specific times. Professor Nathanson had not offered any evidence of the extent to which the GMC 1997 *Guidance* had ever been applied to consent for HCV testing. He also questioned whether HCV was a ‘serious communicable disease’ in terms of the 1997 publication of that name.<sup>142</sup>

**32.148** Professor Ludlam also disagreed with the view that HCV was a serious communicable disease in terms of the GMC 1997 Guidelines. In his view:

HCV was known to be a slowly progressive disease in some individuals, treatment was effective in some, the chance of death was small, in the early 1990s it was not known to be sexually transmitted (and even with current information sexual and needle stick transmission is rare), it rarely affects the type of employment, it does not affect the ability of individuals to travel and does not reflect sexual orientation.<sup>143</sup>

**32.149** Dr Hay also commented on Professor Nathanson’s reliance on a comparison between testing for HIV and HCV and, in line with the comments noted above, suggested that the situation for HCV was different in a number of important respects. First, most patients with haemophilia had been monitored for liver function from the late 1970s and

<sup>136</sup> Ibid [PEN.018.1186] at 1211

<sup>137</sup> Dr Hay – Day 83, page 115

<sup>138</sup> Ibid page 116

<sup>139</sup> Ibid pages 117–118

<sup>140</sup> Dr Hay’s commentary on Professor Nathanson’s report [PEN.018.1349]

<sup>141</sup> The other texts were the GMC *Guidance on HIV Infection and AIDS* (1988) and the BMA *Philosophy and Practice of Medical Ethics* (1988).

<sup>142</sup> Dr Hay’s commentary on Professor Nathanson’s report [PEN.018.1349] at 1352

<sup>143</sup> Professor Ludlam’s commentary on the evidence of Dr Hay and Professor Nathanson [PEN.018.1246] at 1249

would (or should) have been told that they had NANB Hepatitis if their liver function tests were abnormal and other causes had been eliminated. In such cases, an HCV test would have been confirmatory and, if discussed with the patient, may well have been presented as such. Once the Hepatitis C virus had been isolated in 1989 it was assumed to be the cause of most abnormal liver chemistry in this group. Secondly, at the time routine testing was introduced in 1992-93, treatment was available and the prognosis, even without treatment, was regarded as generally very good, in marked contrast to HIV/AIDS before the introduction of HAART in 1995.<sup>144</sup>

**32.150** He commented that in most cases it was likely that HCV testing would have been mentioned in passing in the early 1990s, as a test they intended to carry out. Formal consent for testing would not necessarily have been sought and the patient would (or should) have been told the result at their next clinic visit. He again contrasted the practice of hepatologists and haematologists. He stated:

I should also point out that hepatologists have never had a policy of taking specific consent for HCV testing. I have discussed this with our current Hepatologist and his two predecessors all of whom told me that it would be just one of a battery of [perhaps 15–20] tests conducted as part of the investigation of every patient they investigated for abnormal liver function tests and that each of these tests would not be discussed with the patient individually. As our current Hepatologist said: “Everyone checks the Creatinine [test of kidney function] all the time and that is never discussed with the patient in advance and yet the prognosis of a patient with an elevated Creatinine is very much worse than the prognosis of a patient with HCV”. He re-iterated the point that HCV is potentially curable and even untreated has a generally very good prognosis and that there is no specific guidance.<sup>145</sup>

**32.151** In contrast to hepatologists, Dr Hay understood that haematologists tended to tell their patients that they were testing for HCV and discussed the condition prior to testing. That was his practice. It was influenced by experience with HIV but counselling for HCV testing was never as involved or as prolonged as for HIV testing.<sup>146</sup>

**32.152** As Dr Hay understood it, most HIV and HCV tests are currently conducted in community or STD clinics where the counselling which now always takes place can be ‘relatively perfunctory’.<sup>147</sup> It will often take the form of the patient being given an information leaflet and being asked prior to testing whether they have any questions arising from reading the leaflet. Routine testing of blood donors follows the same pattern.

**32.153** Having also considered Professor Nathanson’s first report (on HIV/AIDS), Dr Hay took up her comparison of the position in the USA. He said:

Professor Nathanson makes the very valuable point that: “In general the UK, unlike the USA, does not have a legal requirement for treatment to require fully informed consent. Ethics advice [in the UK] over three decades has been that

<sup>144</sup> Dr Hay’s commentary on Professor Nathanson’s report [PEN.018.1349] at 1353

<sup>145</sup> Ibid [PEN.018.1349] at 1354

<sup>146</sup> Professor Ludlam was critical of Professor Nathanson’s attempt to equate HCV testing with HIV testing from 1990 onwards, as he understood it. In his view this was an inappropriate comparison. He said that there are many potential causes of abnormal liver function, and to explain all of the implications of these many causes would be impossible in the everyday clinical setting. Once the cause of the abnormal liver function has been identified and HCV is the source, then the doctor can concentrate on the specific implications of the HCV infection. Professor Ludlam’s commentary on the evidence of Dr Hay and Professor Nathanson [PEN.018.1246] at 1248

<sup>147</sup> Dr Hay – Day 83, page 136

the patient must have sufficient information to understand the choice they are making and to make that choice freely.” We tell patients about common complications, not every possible thing that could possibly happen, however unlikely. By the same token, we do not go into chapter and verse about every single test we do. If we did, we would do nothing else. There are practical limitations to informed consent.<sup>148</sup>

**32.154** These practical limitations are (a) the time required to provide full information and take full consent for every test (over 20) to be conducted following a routine appointment for someone co-infected with HIV and HCV would take two or three hours for every patient and even then would be incomplete; and (b) given that first limitation, the difficulty in selecting which of those tests to explain and obtain consent for.<sup>149</sup> The definition of a life-changing result from testing was not straightforward and perceptions changed over time. He noted that the consent process for HIV infection had actually been ‘downgraded’ since 1995, when the disease became well-controlled.

### *Professor Nathanson’s views on Dr Hay’s commentary*

**32.155** Professor Nathanson was referred to Dr Hay’s commentary on her Inquiry statement.<sup>150</sup> Her analysis of Dr Hay’s comments led her to believe that her use of the word ‘counselling’ was perhaps the cause of the sticking point between their two views.

**32.156** Dr Hay’s practice was described to Professor Nathanson by counsel, namely that he would advise patients that he wanted to carry out an HCV test, give them an ‘exposition’ of the disease, and effectively secure their agreement to proceed. Professor Nathanson said that that accorded with best practice for counselling in the period relating to HCV testing.<sup>151</sup>

**32.157** Leaving aside the semantics that occupied some time at the Oral Hearing of her evidence, Professor Nathanson’s views on the appropriate approach to patients offered HCV testing emerged clearly. In the first place she distinguished the requirements for pre-test counselling from those developed for HIV testing. HIV presented a much more complex situation and a correspondingly complex level of information was necessary. Some people assumed that that level of information was necessary for every test but that was never the position in practice. Counselling had to be appropriate to the test in question. HCV and HIV/AIDS were different conditions, with very different medical and social outcomes.<sup>152</sup>

**32.158** She thought that Dr Hay had considered that she was ‘writing from an ivory tower’ without considering the practicalities and that he had missed the nuances in her report: best practice was about being sensitive to the needs of the particular patient and the elements of the medical condition in question.<sup>153</sup> She said that, because the UK does not have informed consent as a legal requirement for almost any treatment, the BMA continued to refer to ‘real or valid consent’ which means that patients must understand enough about the options to be able to make a choice, and to then make that choice. Doctors give patients information, helping them to understand what options are available to exercise their choice. She considered that pre-test counselling was, ultimately, a very

---

<sup>148</sup> Dr Hay’s commentary on Professor Nathanson’s report [PEN.018.1349] at 1355

<sup>149</sup> Ibid

<sup>150</sup> Ibid

<sup>151</sup> Professor Nathanson – Day 84, page 38

<sup>152</sup> Ibid pages 38–39

<sup>153</sup> Ibid page 39

simple concept: it was the process of giving people enough information to make an informed decision.<sup>154</sup>

**32.159** Professor Nathanson suggested that Dr Hay appeared to assume ‘full consent’ was analogous to lengthy pre-test counselling and that a practitioner was expected to give every single piece of information on testing to a patient. She stated that she was not saying in her report that patients need to be told everything about testing in order to consent but rather that information has to be adapted to their individual requirements. Professor Nathanson concluded this aspect of her evidence by stating: ‘The problem is that ... consent is not necessarily a highly complicated process. It just has to be a process that is specific and appropriate for that patient and that test’.<sup>155</sup>

**32.160** Professor Nathanson’s attention was then drawn to Dr Hay’s view that, if informed consent was required for every test that a doctor did, it could take up most of the day and normal work would not be done. In response, Professor Nathanson remarked one had to establish what was meant by ‘real consent’. A doctor may not necessarily explain to the patient all of the tests that would be done on a blood sample. The doctor’s skill would be in communicating with the patient that a series of tests will have to be done on a blood sample and tailoring further information to the individual patient. Some patients will simply want to get on with those tests and not ask for an explanation of them at this stage; others may want to know from the beginning what all of the tests are, in which case the doctor should recognise that they have to explain them and what their purpose is. The doctor should respond to the requirements of the individual patient.<sup>156</sup>

**32.161** Professor Nathanson noted that some tests are more risky or hazardous. For example there are specific risks with performing a biopsy and those risks should always be explained to the patient. However, in her view, a doctor may not necessarily go into all of the risks associated with every intervention with a patient but, rather, should explore the most common and the most serious of the risks in the first instance. If, after that, a patient wants to have more information then it should be provided. Professor Nathanson summarised her position:

[S]ome patients will want to know more and some patients will want to know very little, and that is consent, because that is valid because the patient has been offered information and the opportunity to ask questions and has said, “That satisfies my need.”<sup>157</sup>

**32.162** Professor Nathanson was asked to comment on Dr Hay’s distinction in approach taken by different specialists and, in particular, the example given of the difference between a hepatologist and a haemophilia clinician in obtaining consent to conduct tests. She agreed that patients are referred to a hepatologist because they already have abnormal liver function and the hepatologist would then carry out the appropriate investigations. It is likely that such a patient will have already been treated by another clinician who made the referral to the specialist so that the patient should have knowledge that there is something wrong with their liver and consent to further investigatory tests is implied. Professor Nathanson would consider this to be ‘necessarily implied consent’.<sup>158</sup> She would

---

<sup>154</sup> Ibid pages 40–41

<sup>155</sup> Ibid page 46

<sup>156</sup> Ibid page 44

<sup>157</sup> Ibid page 45

<sup>158</sup> Ibid page 49

expect a hepatologist to obtain specific consent for a liver biopsy, because of the specific, well-documented and occasionally serious risks associated with the procedure, but not for tests carried out on blood samples. She would expect a hepatologist to explain that blood was being taken for testing to try to identify the cause of the liver disease and also expected that the patient would acquiesce to that general statement and, in those circumstances, that in her view would constitute consent.<sup>159</sup>

**32.163** Professor Nathanson was also referred to the final section of Dr Hay's commentary where he listed the main differences between HIV and HCV that he felt were relevant to counselling:<sup>160</sup> Dr Hay's comparison is shown in Table 32.1 below.

**Table 32.1: Dr Hay's comparison of characteristics of HIV and HCV**

<u>HIV</u>	<u>HCV</u>
Incurable, even now	Curable in 40-100%
70% Mortality prior to 1995	Mortality <2% prior to 1995
Prior to 1995 expected 100% mortality	Good prognosis, slow or no progression
Treatment ineffective prior to 1995	No treatment until late eighties
Ready sexual transmission	Low infectivity
Symptomatic when advanced	Generally asymptomatic until end-stage
Causes AIDS	30% cirrhosis, eventually 5% hepatocellular carcinoma
Uninsurable	May have an adverse effect on premium

**32.164** Professor Nathanson agreed with the details Dr Hay had listed in his table and accepted the distinctions he had made between the two viruses and, in particular, their relevance to counselling. She observed this was 'an entirely appropriate background to the way in which you would talk to the patient about consent or indeed about what the diagnosis would mean to them'.<sup>161</sup>

### *Dr Alexander*

**32.165** Dr Alexander was Consultant Hepatologist at Addenbrooke's NHS Trust from August 2003 and had extensive experience in hepatology prior to that appointment. He provided the Inquiry with a report about the tracing and testing of patients who might have been infected with Hepatitis C and the information given to patients who might have been or were infected with the virus.<sup>162</sup> Dr Alexander was asked how he advised patients that they had a positive HCV test, both in the early days of testing and after 1995. He had a similarly pragmatic approach to Dr Hay. He said that the introduction of HCV testing was a major step forward, allowing him and his colleagues to separate patients into those who had probably cleared the infection from those with ongoing infection. There were, however, concerns about the quality of the tests themselves and a lack of knowledge of the natural history of Hepatitis C.<sup>163</sup>

<sup>159</sup> Ibid page 48

<sup>160</sup> Dr Hay's commentary on Professor Nathanson's report [PEN.018.1349] at 1358

<sup>161</sup> Professor Nathanson – Day 84, page 50

<sup>162</sup> Letter from Penrose Inquiry to Dr Alexander requesting a report [PEN.018.1241]

<sup>163</sup> Dr Alexander's statement on HCV testing [PEN.018.1360] at 1365

**32.166** Dr Alexander said that in the early 1990s patients with positive HCV tests were warned that the doctors did not understand fully the implications of the test and as a consequence patients underwent regular testing for HCV. In his centre in Cambridge all HCV-positive patients were also offered the opportunity of a liver biopsy. Patients with liver damage were offered close follow-up and regular liver biopsies. At this time there was no available therapy for such patients.<sup>164</sup>

**32.167** He observed that knowledge gained by physicians seeing patients with NANB Hepatitis may not have been applicable to dealing with patients when HCV tests were introduced. He commented:

It was not possible to transpose the information we gained from non-A, non-B hepatitis epidemiology studies to HCV infection because introduction of testing had identified a far greater spread and number of patients than we had imagined prior to 1991.<sup>165</sup>

**32.168** Dr Alexander also commented on changes in the information given to patients from 1995 onwards. In his statement he said that ‘issues such as the natural history were still being resolved but studies of vertical transmission and sexual transmission were allowing us to fine tune the information given to patients’.<sup>166</sup> He added in oral testimony that in this time period the clinicians could advise on the effect on HCV of co-factors such as age, gender and obesity.<sup>167</sup>

*Differences of opinion regarding the provision of information to patients about NANB/Hepatitis C*

**32.169** It appeared from the written statements of Professor Nathanson and Dr Hay that there might have been significant differences of opinion between them concerning proper ethical practice in relation to the provision of information to patients about NANB Hepatitis and HCV and about the proper approach to discussions about testing in that context. Dr Hay was concerned that Professor Nathanson, despite acknowledging changes in scientific knowledge throughout the period, had not properly taken into account the significance of those changes. Professor Nathanson thought that Dr Hay had misinterpreted her evidence as prescribing a higher level of counselling than she had intended to convey was necessary. That there were differences is obvious but, in the end, after their oral testimony is taken into account, the differences appear to be largely differences of expression rather than of substance.

**32.170** Professor Nathanson acknowledged that best practice had to reflect changes in scientific understanding over time. Dr Hay, as a haemophilia practitioner with experience of dealing with those changes, gave considerable weight to their significance and in particular emphasised the chronology of emerging knowledge as it bore on practice.

**32.171** It is consistent with Dr Hay’s evidence that by 1985, when the first diagnostic test for HTLV-III/HIV was becoming available, neither the GMC nor the BMA had published specific guidance on NANB Hepatitis in the management of patients. There was no test for any NANB Hepatitis virus and therefore no trigger for discussion of the implications of testing patients. Thereafter, as Dr Hay put it, there was ‘much discussion and a plethora of

---

<sup>164</sup> Ibid [PEN.018.1360] at 1365

<sup>165</sup> Ibid [PEN.018.1360] at 1366

<sup>166</sup> Ibid

<sup>167</sup> Dr Alexander – Day 85, page 143

guidelines issued over the years to cover HIV-testing',<sup>168</sup> culminating in the GMC publication *HIV Infection and AIDS: the Ethical Considerations* (1988). It would be impossible to hold that, before the AIDS era began, there was a generally recognised obligation on doctors to single out NANB Hepatitis as a subject for specific discussion with patients, either in the course of haemophilia therapy or more generally.

**32.172** Professor Nathanson recognised that dealing with HIV/AIDS changed the way that medicine was practised. Dr Hay emphasised that HIV/AIDS overshadowed hepatitis. In the critical period, 1982 to the mid-1980s, patients were not counselled about NANB Hepatitis to the same degree as had been common in the immediately preceding period. There was growing knowledge that a proportion of patients with NANB Hepatitis were developing severe progressive liver disease but it was still believed that the majority would have a non-progressive or very slowly-progressing disease and, as noted, HIV/AIDS assumed a position of paramount importance at this time.

**32.173** So far as formal statements of practice are concerned, the ethical position relating to NANBH/HCV remained relatively ill-defined, depending on general rather than specific guidance even in 1988. UKHCDO guidance was related primarily to the selection and use of therapeutic products. Professor Nathanson's views were largely based on the 1988 *Guidance*. That BMA publication did not refer specifically to hepatitis, however. By 1988 it was understood that NANBH/HCV was a disease with a potentially serious prognosis, as set out in Dr Hay's table (Table 32.1). If the 1988 *Guidance* had been intended to specify proper ethical practice in relation to that disease it would have required discussion and express guidance, not least to differentiate the guidance offered from that applicable to HIV/AIDS. The debate over the need for 'counselling' and what that meant in different contexts makes that clear.

**32.174** Further, Professor Nathanson's view that much would depend on the individual patient is inconsistent with the notion that there was a well-developed and understood ethical rule requiring haemophilia clinicians invariably to adopt a particular approach to procedures relating to testing patients as a matter of general practice in the early 1990s. Implementing the general guidance left much to the discretion of the clinician in managing patients.

**32.175** Examination of proper practice in the period from 1997 further undermined the case for a specific duty to advise patients before testing for HCV infection at any earlier period. Dr Hay stated that hepatologists have never had a policy of taking specific consent to HCV testing: it was just one of a battery of tests to be performed routinely on blood samples taken from patients referred to them.<sup>169</sup> Haemophilia clinicians tend always to tell the patient if they are testing for HCV and to discuss the condition prior to testing.<sup>170</sup> Professor Nathanson's explanation was that liver specialists would expect that at an earlier stage in the process another clinician would have provided the necessary information. It appears reasonable to suggest, however, that if there had been a specific ethical rule that patients required to be counselled before being tested for HCV, a hepatologist would have had to check that prior counselling had been given. On the evidence of both experts, counselling was and is perfunctory in those situations.

---

<sup>168</sup> Dr Hay's commentary on Professor Nathanson's report [PEN.018.1349] at 1355

<sup>169</sup> Ibid

<sup>170</sup> Ibid [PEN.018.1349] at 1354

**32.176** In the circumstances, Dr Hay's evidence that there has never been any specific advice from either the BMA or the GMC or any other body about consent or counselling for HCV testing is accepted.<sup>171</sup>

**32.177** Apart from express guidance, both experts in the end looked to the wider context of growing scientific knowledge and changing perceptions of the doctor/patient relationship in identifying milestones in the development of the requirements of good ethical practice. Professor Nathanson expected that as knowledge of NANB Hepatitis and later HCV developed clinicians would pass on that information to their patients. By 1985 clinicians would have been expected to advise patients clearly of the risk of contracting the disease from the use of factor concentrates. By 1991 a clinician would have been expected to advise patients clearly of the risks associated with any medical intervention, including testing. Dr Hay considered that the years 1991–92 were particularly significant because of the introduction of specific testing for anti-HCV. However, he observed that by then treatment was available and the prognosis for patients infected with HCV was regarded as generally good. Dr Hay said that in most cases HCV testing would be mentioned in passing and formal consent to testing would not have been sought.

**32.178** It is not possible to find that up until 1988 there was a well-developed and widely recognised ethical duty, of any degree of specificity, to advise patients about the nature and implications of NANB Hepatitis or (after the isolation of HCV in 1988) of Hepatitis C. Indeed, on detailed discussion, Professor Nathanson's evidence fell short of suggesting that there was.

**32.179** As far as testing was concerned, Professor Nathanson considered that the 'gold standard' of care would involve obtaining patients' consent before testing blood samples for HCV, whether they were stored or fresh. However, she acknowledged that haemophilia patients monitored for liver function throughout the 1980s could have expressly consented to a future HCV test when blood was taken or have been held to have implicitly consented on the basis that a specific HCV test was effectively a confirmatory test for a patient who had already been told that it was likely that they had NANB Hepatitis due to persistent irregular liver function tests. However, once results were obtained, as with an AIDS diagnosis, they should have been communicated to the patients.

**32.180** There are difficulties with this as a basis for a rule of practice. Professor Nathanson acknowledged that some patients had difficulty processing bad news or complex information during consultations with clinicians and she offered this as an explanation of why some patients may not have retained information that they have been given. The memories of clinicians can be similarly fallible, and, without a record, clinicians in succession would not know what consents their predecessors had obtained.

**32.181** In practice, based on general guidance from the late 1980s and influenced by the experience of HIV/AIDS, haematologists and haemophilia specialists in particular have provided information about HCV and about testing for the disease as an aspect of their care and management of their patients. Practice has been variable, reflecting the approaches of individual practitioners, including Dr Hay and Dr Alexander. In adapting general ethical principles to specific circumstances that is inevitable.

---

<sup>171</sup> Ibid [PEN.018.1349] at 1352

**32.182** However, broadly speaking, Professor Nathanson and Dr Hay agreed that, as knowledge increased, patients should have been told about the risk of infection with HCV and that patients should have been told about the changing views about the severity of the disease as they developed. They agreed that it was appropriate to obtain consent before proceeding with an HCV test although a failure to do so for a haemophilia patient who had already given consent to have their liver function monitored for the purpose of investigating, amongst other things, NANB Hepatitis was understandable. Both agreed that the extended pre-test counselling that was appropriate before an HIV test in the 1980s is not necessary today with regards to HCV and was not necessary during the earlier period either. This level of common understanding left considerable scope for variation in individual practice.

### **The current position in general**

**32.183** It is clear from the evidence that there have continued to be significant developments in the provision of information to patients. As Professor Nathanson saw it, the modern approach to the doctor/patient relationship involves the patient fully in the decision-making process: it sees medical practice as being about sharing. The doctor does not assert that he knows everything but adopts the approach that 'This is how I would interpret the information you are giving me and what I'm learning about you from tests'. There was a radical shift from 'Doctor knows everything and will give orders' to 'We will share information and my role is to help you make a decision'.<sup>172</sup>

**32.184** Professor Nathanson explained what would constitute best practice in terms of the provision of information to patients:

[T]he most important thing is about offering information to patients, not pushing information at them. It's about helping patients to come to terms with information, giving them the opportunity to think and to question, and being open to a repeated set of questions, rather than delivering a measured amount of information each time, which is identical for each patient .... It has to be what's right for that patient at that time ... and trying to test, which is where the communication skills also come in ... that they have understood sufficient to be able to make a decision based upon the information that you are offering.<sup>173</sup>

**32.185** In modern practice in the UK, in contrast to much of the reference period, this extends to providing the patient with sufficient information to allow the patient both to understand the choice they are making and to enable the patient to make that choice freely. What is 'sufficient' will vary from patient to patient and will depend on what the patient wants to know as well as what the major risks, benefits and alternatives are. In the modern situation, a doctor is trying to make sure that the patient understands enough to make an informed decision: it is more complicated than under the regime that obtained until the late 1980s and early 1990s. In addition there are many more treatment choices available. In modern practice, ethics is considered to be far more complex and nuanced than in the past and the right thing to do is not always clear.

---

<sup>172</sup> Professor Nathanson – Day 37, pages 11–12

<sup>173</sup> Professor Nathanson – Day 84, pages 4–5

**32.186** The aim of the GMC publication *Good Medical Practice* (see paragraph 32.191 below) is to give advice, supplemented by the BMA, the Medical Defence Union and other medical defence bodies, which will help doctors to be better at their job and to follow best practice. The general direction of movement in medicine after the 1970s, away from paternalism and towards patient-centred medicine, had taken a long time, however, and according to Professor Nathanson it is still ongoing.

**32.187** There was broad agreement that there had been significant change over the reference period. As with any progressive, but relatively unstructured, development in patterns of behaviour, it can be difficult to define with any precision the point reached in general understanding of the evolving scene at any given time, in the absence of specific regulation or guidance providing a reference date. It can be particularly difficult to relate general understanding to the position of a doctor trying to assess the needs of patients presenting with a particular set of circumstances. This was particularly true in the mid-1980s with the advent of AIDS. Even now, there are still unsettled or unresolved issues.

**32.188** Quite what 'patient-centred care' requires of the doctor varies with circumstances. Two patients with the same medical condition may not necessarily want the same solution. Doctors now recognise that different patients may have different views and priorities. One patient with a serious condition might prefer to be pain free and another might prefer to be more alert and aware and able to interact with their family. The underlying concept is that the patient should be comfortable with whatever is done: it is the patient's body or illness that is being treated. The doctor has the responsibility of knowing as much as possible about the patient, of looking at the patient holistically as a person and not as a physiological, anatomical specimen. The complexity in any individual case arises because the doctor is trying to give the patient the power to decide whether they want to make a decision about treatment, but not forcing them to do so. The patient's decision could be that they want the doctor to make the decision for them. The fundamental change from the 'paternalistic' approach is that power has transferred to the patient.

**32.189** Professor Nathanson did not think that responsibility had transferred to the patient as well as power. Patients do have the responsibility to tell their doctors the truth about themselves but the patient should not be forced into taking the final decision about their treatment: the patient has to be protected from taking decisions with which they are uncomfortable. It can become very uncomfortable for the doctor where a patient may say that they know that they have a fatal disease and there is a curative treatment but they do not want to accept treatment. The picture painted by Professor Nathanson of the requirements of current ethical practice is very different from that described relative to practice in the period that is of concern to the Inquiry.

**32.190** She explained that there has been a dialogue with the public on the principles of medical ethics. Half of the BMA committee are now lay people or non-doctors. The BMA commissions pieces from members of the public and involves them in conferences. For example, with topics such as consent and assisted dying the BMA has taken into account the views of the public. The aim is to produce an ethical framework that is a balance between what doctors and the public expect.<sup>174</sup>

<sup>174</sup> Professor Nathanson – Day 37, page 27

## Current guidance on HCV

**32.191** In terms of formal guidance, the current approach was set out in the GMC booklet, *Good Medical Practice* and the supplement from June 2008, *Consent: patients and doctors making decisions together*.<sup>175</sup> Professor Nathanson noted the GMC's current guidance on the information that should be given to patients in her first report to the Inquiry:

You must give patients the information they want or need about:

- (a) The diagnosis and prognosis
- (b) Any uncertainties about the diagnosis or prognosis, including options for further investigations
- (c) Options for treating or managing the condition, including the option not to treat
- (d) The purpose of any proposed investigation or treatment and what it will involve
- (e) The potential benefits, risks and burdens, and the likelihood of success, for each option; this should include information, if available, about whether the benefits or risks are affected by which organisation or doctor is chosen to care
- (f) Whether a proposed investigation or treatment is part of a research programme or is an innovative treatment designed specifically for their benefit
- (g) The people who will be mainly responsible for and involved in their care, what their roles are, and to what extent students may be involved
- (h) Their right to refuse to take part in teaching or research
- (i) Their right to seek a second opinion
- (j) Any bills they will have to pay
- (k) Any conflicts of interest that you, or your organisation, may have
- (l) Any treatments that you believe have greater potential benefit for the patient than those you or your organisation can offer.<sup>176</sup>

**32.192** Professor Nathanson explained that the GMC had been producing versions of *Good Medical Practice*<sup>177</sup> for some years and it became clear over time that more detail was required on the issues of both 'consent' and 'confidentiality'. The GMC therefore put together a more detailed document on consent:

[T]o help doctors in making decisions about whether or not a patient could give consent, whether it was appropriate for somebody else to consent for that patient and about how to go about the process of giving patients information so that those decisions could be made ... this is about patients and doctors making decisions together. And that's a very deliberate decision by the General Medical Council, to stress that consent is not about a doctor deciding to do something and the patient then agreeing the doctor could do it, it's about that process of decision-making together, and that is very much a change of

---

<sup>175</sup> 'Guidance for Doctors', *Consent: patients and doctors making decisions together*; General Medical Council [PEN.018.0430]

<sup>176</sup> *Ibid* [PEN.018.0430] at 0441

<sup>177</sup> The GMC's general ethical guidance.

emphasis from say, the 60s or 70s, when it would be more about a patient agreeing to what a doctor had suggested.<sup>178</sup>

**32.193** Professor Nathanson identified what she took to be the key statement on consent in the 2008 guidance:

5(b) The doctor uses specialist knowledge and experience and clinical judgement, and the patient's views and understanding of their condition, to identify which investigations or treatments are likely to result in overall benefit for the patient. The doctor explains the options to the patient, setting out the potential benefits, risks, burdens and side effects of each option, including the option to have no treatment. The doctor may recommend a particular option which they believe to be best for the patient, but they must not put pressure on the patient to accept their advice.<sup>179</sup>

**32.194** Professor Nathanson explained that the importance of this paragraph was its emphasis on setting out all medical treatments, or options for treatment, and making it clear that the role of the doctor is to use his or her knowledge, skills and experience to understand what a patient wants and using that to identify what investigations or treatments will result in overall benefit. This section is not specific to a particular condition or type of test but encompasses all conditions and all tests.<sup>180</sup>

**32.195** She said that doctors are expected to offer their patients all of the elements of information identified in the guidance. In addition she said:

Many doctors today back up their information sharing with leaflets, or web links, so that patients and relatives are better able to make sure they have all the information they want and can test their recollections of the conversation with the doctor.<sup>181</sup>

**32.196** She commented that patients have a basic right to information about themselves. This does not mean that doctors simply hand over the information, including test results, however. Information should be shared with the patient in an appropriate manner:

In practical terms this means telling the patient where this places him/her in terms of a differential diagnosis, and what further tests are necessary, or what treatment now seems to be indicated.<sup>182</sup>

**32.197** Professor Nathanson was of the view that the guidance given by the GMC was a 'counsel of perfection' but she did not accept that it was provided by a body that was out of touch with the realities of clinical practice. She stated that it was not necessary for a practitioner to set out 'every single detail of every single option'. The guidance in this paragraph concerned the offering of information, understanding the patient's views and exploring options with them. By understanding the patient's views some options could be discounted and would not need to be explained further. In her view the guidance was that a skilled doctor should prioritise the most important pieces of information for their patient. The process is often somewhat easier in the relationship between a patient and

<sup>181</sup> Professor Nathanson's supplementary statement [PEN.018.0419] at 0420

<sup>182</sup> Professor Nathanson's first report to the Inquiry [PEN.012.0330] at 0337

their GP, because GPs often know their patients better than specialists to whom they may be referred and a lot of decision-making is broadly similar for different conditions. She accepted that for some patients and for some tests and procedures it can take a long time to obtain valid consent but, equally, very often it takes a short time. She explained that ‘practising doctors on my committee, for example, ten people who are in everyday clinical practice, say, “This doesn’t cause a problem”’.<sup>183</sup>

**32.198** The family members of competent adult patients have no right to know a diagnosis. Doctors should work with patients to help them understand the benefits of sharing their diagnosis with others but cannot force them to share the information.

**32.199** In oral evidence Professor Nathanson expanded on the issue of what, and how much, information a doctor should offer to a patient. She explained that the BMA is aware that the amount of information a patient can take in and accurately recall from one-to-one meetings with their doctor can be very limited. This can be affected by the patient being upset and anxious about what is happening to them. Increasingly, doctors will offer brief information leaflets or links to helpful and specific websites to their patients so they can conduct their own research and find out more themselves.<sup>184</sup> It is hoped that this approach obviates the risk of patients using unreliable or inaccurate websites, which can be unsafe, in their own research. The doctor can try to steer the patient to the sites that are reputable and this should help the patient to ask the right questions of the doctor.<sup>185</sup>

**32.200** Professor Nathanson explained that, when seeking agreement to carry out a test, information should be offered to explain why it is being performed, what the test might show and what decisions will be made in respect of the results.<sup>186</sup> In oral evidence she expanded this point by explaining that the contemporary approach to ‘seeking agreement to tests’ will depend on the circumstances. For example an individual may approach their GP because they have been feeling unwell and this may lead to the GP conducting tests for possible anaemia. The doctor could explore the patient’s medical history with them in their discussion and, based on what they found out, decide which tests are appropriate. Some patients will want to know what these are and some will prefer to await the results and then have the test results explained.<sup>187</sup>

**32.201** Offering information about testing, and deciding how much information to give, depends on the patient and what the doctor thinks they might discover in the test. The test for anaemia may be routine but there are many causes of anaemia, with some being minor and some very serious, such as leukaemia. It is not necessary that the doctor should tell the patient about the most serious possibilities at the outset: ‘How much you offer, how much information really depends upon what you think is likely to come out of that test’.<sup>188</sup> If the patient asks specifically if there could be a serious reason for the anaemia, such as cancer, then the doctor should be honest that it is a possibility, but go on to explain there is a more likely less serious cause.

**32.202** The information that a clinician gives to a patient may depend on the suspicions they have about the patient’s diagnosis or likely test results; but it also depends on the implications of the test results. If a clinician thinks the result will be negative and the test is

---

<sup>183</sup> Professor Nathanson – Day 84, pages 8–9

<sup>184</sup> *Ibid* page 10

<sup>185</sup> *Ibid* page 11

<sup>186</sup> Professor Nathanson’s supplementary statement [PEN.018.0419] at 0420

<sup>187</sup> Professor Nathanson – Day 84, page 12

<sup>188</sup> *Ibid* page 12

one of exclusion, they may not give a detailed explanation of what a positive result would mean. By way of contrast, if the clinician thinks the test result will be positive they should go into more detail about the implications of such a result. Once there is a diagnosis, the amount of information given to the patient will increase and become more detailed.<sup>189</sup> As explained by Professor Nathanson, the provision of information may be a graduated process, depending on what the clinician expects to find from a test and whether it is the initial test of a possible series of tests, at which point a relatively small amount of information may be offered.<sup>190</sup> Generally speaking a clinician should modify every piece of information that is given to the patient depending on their circumstances.

**32.203** She also explained that, in the case of ongoing, routine monitoring tests, doctors may require to provide more information than that given at an earlier period as the implications of the test results may change over time. These changes may be due to emerging knowledge about the natural history of the illness or different treatment options becoming available. They may also be due to non-medical factors such as changing public perceptions of a disease:

Another element that is relevant when testing for medical conditions with specific non-medical consequences, such as social stigma, or employment and financial consequences is that these should be part of the discussion. It should again be noted that such stigma or financial consequences emerge over time.<sup>191</sup>

**32.204** Testing for HIV has had obvious non-medical consequences, financial and social, from a very early stage. Some people think HCV is also stigmatising and can have social consequences; it can also have employment consequences in some circumstances.<sup>192</sup> In 1992, when a great deal of HCV testing was first carried out, doctors conducting the tests could not have known what the non-medical implications of a positive diagnosis would be. Professor Nathanson added that doctors would also have had limited knowledge of the medical consequences as HCV was a condition that was learned about by tracking infected patients over a long period of time.<sup>193</sup>

**32.205** Professor Nathanson was asked to sum up what she considered to be best practice today in testing for Hepatitis C:

It comes back to the consent paragraph that I quoted from the General Medical Council's book. It's about giving the patient enough information to make a decision about having that test. That means a short discussion. It is not the most serious chronic illness. It is a serious chronic illness but it is not the most serious. It is not the worst diagnosis you could be faced with. You do need to give patients some information about it, not least to make sure that they are aware that this is something that, if it's positive, you are going to want to follow them up with, and that you would want, therefore, this to be potentially the beginning of quite long period of follow-up, including potentially some quite complex treatment.<sup>194</sup>

<sup>194</sup> Ibid page 20

**32.206** In light of the discussion of terminology in this chapter, it is appropriate to make a general observation about the use of the word 'counselling'. It was clear from the evidence heard by the Inquiry that this term was used by different people in different ways and at different times. While the guidance given by the GMC and the BMA to doctors is a matter for them, the confusion that entered the evidence, especially of Professor Nathanson and Dr Hay, from the use of a term of uncertain meaning should encourage the responsible bodies to ensure that official guidance and rules are expressed with sufficient clarity to have an obvious meaning or are supported by clear definitions of the scope of significant terms in context, in order to avoid confusion. The written guidance that they produce is and has always been important to practitioners but perhaps increasingly it is also important to patients, who are entitled to look to these official sources as indications of what they are entitled to expect from their medical practitioners.

**32.207** In conclusion, this chapter has discussed the medical profession's views on ethical practice relating to consent for testing for HIV and HCV, and in relation to the information provided to patients on these conditions. Although the three experts featured have some differences of opinion and emphasis, they broadly agree that best practice now in relation to informed consent and even in the sharing of information differs from the practices which prevailed during the reference period, or at least up until 1988 when the influence of HIV/AIDS helped to bring about significant changes. Dr Hay and Professor Nathanson agree that there was a qualitative difference between the nature of HIV/AIDS and Hepatitis C which, they concluded, meant the requirements for informed consent and information to patients were less onerous in relation to Hepatitis C. While their evidence is accepted, it must be acknowledged this will not bring consolation to the many patients and relatives troubled by what they see as a lack of informed consent or a lack of information in their own particular circumstances. Those suffering from HCV, especially those who progress to liver cancer, may find views that compare their condition favourably with other infections unpalatable. Some people who struggle with chronic Hepatitis C may also be experiencing repeated failed treatments for the virus. Whilst HCV is perhaps, in Professor Nathanson's words, 'not the worst diagnosis you could be faced with', for such individuals it was and continues to be devastating.

## CHAPTER 33

### AN INVESTIGATION INTO THE SYSTEMS IN PLACE FOR INFORMING THE PATIENTS ABOUT THE RISKS – HIV/AIDS

#### Introduction

##### *Scope of the chapter*

**33.1** The background to the development of doctor/patient relationships during the reference period has been discussed in Chapter 32, *An Investigation into the Systems in Place for Informing Patients about the Risks – Ethical Context*. Particular matters dealt with in this chapter include: (i) the information and advice given by doctors about the risks associated with the therapeutic use of blood and blood products, (ii) the clinical information and prognosis given to patients and, where appropriate, their families in the investigation and diagnosis of HIV/AIDS and (iii) the testing of blood samples of patients in specific situations.

**33.2** The HIV/AIDS epidemic had little impact on the treatment of blood coagulation disorder patients anywhere until 1982 and in the United Kingdom few patients (and none in Scotland) were known to be infected or to have AIDS until mid-1983. In late 1984 and in 1985 testing and screening for anti-HTLV-III/HIV<sup>1</sup> disclosed a prevalence of infection, in particular in coagulation disorder patients, which had not been anticipated. The main events bearing on developing relationships between doctors and patients occurred for the most part in and after 1983.

**33.3** Changes in knowledge of the risk of transmission of HIV, and of the threat that the infection posed for patients, did not occur uniformly throughout the UK, or within Scotland. There are few landmark dates that apply generally. The publication in *The Lancet* of 1 September 1984 by Cheingsong-Popov and others of their study of the prevalence of antibody to HTLV-III in AIDS and AIDS-risk patients in a number of English Haemophilia Centres was one such event.<sup>2</sup> So far as Scotland is concerned, the first reports in late 1984 of HTLV-III/HIV infection in patients in the west of Scotland, treated with both NHS and imported products, and in the south east of Scotland, in patients treated with SNBTS factor concentrates exclusively,<sup>3</sup> demonstrated that the findings of the Cheingsong-Popov study had direct relevance in this country and shattered any continuing belief that the AIDS epidemic was confined to those treated with commercially produced coagulation products.

**33.4** The treatment of events in this chapter is largely chronological. Specific topics discussed include:

- Issues relating to tests of patients' immune functions carried out in Edinburgh and Glasgow in the period 1983–85.
- The circumstances in which testing of patients' sera stored from earlier investigations was carried out in research laboratories in Edinburgh and Glasgow following the advent of the first anti-HTLV-III tests.
- The problems which arose subsequently over obtaining informed consent for anti-HTLV-III testing and pre- and post-test counselling.

<sup>1</sup> See Chapter 29, *The Discovery of HIV and the Development of Screening Tests* for a discussion of LAV/HTLV-III, the early names for what became known as HIV.

<sup>2</sup> Cheingsong-Popov et al, 'Prevalence of antibody to human T-lymphotropic virus type III in AIDS and AIDS-risk patients in Britain', *The Lancet*, 1984; 477-480 [LIT.001.0417]

<sup>3</sup> See Chapter 10, *Knowledge of the Geographical Spread and Prevalence of HIV/AIDS 2*

The evidence of the witnesses who spoke about the effects of their own or their relative's infection with HIV and/or Hepatitis C included evidence on some of the matters discussed in this chapter.<sup>4</sup> Where appropriate the evidence of these witnesses has been referred to in order to give context to each topic. So as not to detract from the main purpose of the oral evidence of these witnesses (for the Inquiry to learn about the full effects of infection) the Inquiry did not investigate each criticism made by these witnesses but instead took account of them when considering and reaching conclusions about the practices of their treating doctors.

### **The threat of HIV transmission, haemophilia therapy in Scotland and the provision of information to patients**

**33.5** As noted in paragraph 32.3 of Chapter 32, *An Investigation into the Systems in Place for Informing Patients about the Risks – Ethical Context*, many of the patient witnesses who provided statements to the Inquiry stated that they were not warned about the risks associated with their treatment for haemophilia.

**33.6** The evidence available to the Inquiry indicates that, as in other areas, individual haemophilia clinicians formed and followed their own views of the appropriate approach to telling their patients about therapy, and the risks associated with it. It is thus not possible to distil one single approach that might be described as common among them.

#### *Practice in Edinburgh and south east Scotland*

#### **The evidence of patients in Edinburgh and south east Scotland**

**33.7** The witnesses who gave evidence about the effects of their own or their relative's infection with HIV and Hepatitis C included four patients or relatives of patients who were treated in Edinburgh.<sup>5</sup> Three of them gave evidence about the provision of information to them or their relatives. As detailed in Chapter 5, *An Examination of the Effects of Infection with HIV on the Patients and their Families, including Treatment*, the witness given the pseudonym 'Mark' recalled the risk of infection with AIDS being discussed at his clinic appointments, usually at the end of the appointment, from 1983–84.<sup>6</sup>

**33.8** The witness 'Elaine' said that, had her husband, 'Brian', known about the risk of HIV/AIDS from his treatment, he would not have taken Factor VIII treatment. She believed that Brian would have reverted to the old treatment (with cryoprecipitate) instead.<sup>7</sup> As detailed in paragraph 5.213 of Chapter 5, Elaine first heard of a person with haemophilia contracting HIV when she read a newspaper article while on holiday in Canada in the summer of 1984. When she discussed the article with Brian on her return home, he completely dismissed it and said that it wouldn't affect him because he was receiving blood products manufactured in Scotland from Scottish blood. It is, unfortunately, clear on the evidence that, unknown to all, Elaine's husband was already infected with HIV when she returned from Canada with the article. However, it would appear from her evidence that her husband had been aware of the risk of infection from commercial concentrates but had been advised that there was no risk, or much less risk, from SNBTS concentrate.

---

<sup>5</sup> See Chapters 5 and 6. Frances, Elaine, Mark and Laura were the witnesses referred to.

<sup>6</sup> Mark – Day 32, page 114

<sup>7</sup> Elaine – Day 31, pages 131–132

**33.9** The witness given the pseudonym ‘Frances’ was unable to say if her father, ‘James’, was specifically warned about the risks associated with his treatment for haemophilia. James took an active interest in his treatment and liked to be kept fully informed, however,<sup>8</sup> and it seems likely that he would have asked and would have received the explanations typically received by those of Professor Christopher Ludlam’s patients who asked about HIV.

### The evidence of Professor Ludlam

**33.10** Professor Christopher Ludlam said that in 1982 very little was known about AIDS in haemophilia patients. By the end of that year a total of seven patients in the USA had been reported to have AIDS out of a population of 20,000 people with haemophilia.<sup>9</sup> He did not discuss AIDS with his patients during 1982 unless they specifically asked him about it and he did not recall there being much concern about AIDS at that time.<sup>10</sup> He said that if he had discussed AIDS in 1982 he would not have had a great deal to say to patients: all he could have said was that there was a possibility that AIDS might be transmitted by blood products.<sup>11</sup>

**33.11** He thought that by the spring of 1983 he had become convinced that AIDS was a syndrome specifically related to a transmissible agent like a virus.<sup>12</sup> There was a meeting of the haemophilia and blood transfusion working group at St Andrew’s House on 22 March 1983,<sup>13</sup> which both he and Professor Charles Forbes attended. It is clear from the minutes of the meeting that there was concern at that time that AIDS might appear in the UK.

**33.12** As the position was understood by Professor Ludlam at that time, the virus was likely to be transmitted through blood products but he did not think that his patients were at risk. It appeared to be a US phenomenon and most of the Edinburgh patients were receiving NHS concentrate manufactured from plasma collected in Scotland, where there was then no evidence of AIDS. The likelihood of the virus being in the Scottish donor pool was small.<sup>14</sup> In early 1983 he therefore did not discuss with his patients the possibility of AIDS infection, or whether they wished to continue with concentrate therapy.<sup>15</sup>

**33.13** Professor Ludlam said that he would not have initiated a discussion about switching from concentrate therapy to cryoprecipitate with patients, although if a patient had asked him he would have discussed it with them. He would have told them that switching from concentrate to cryoprecipitate would not abolish the risk of AIDS but might (or might not) reduce it. He would not have encouraged patients to switch to cryoprecipitate if they were being given home treatment with concentrate.<sup>16</sup>

**33.14** He told the Inquiry that he was not aware of any haemophilia centres in the UK where clinicians initiated discussion of a switch to cryoprecipitate with patients, although he knew of one or two haemophilia centres at which patients had asked about the use of cryoprecipitate.<sup>17</sup>

<sup>15</sup> Professor Ludlam – Day 35, page 82

<sup>16</sup> Ibid page 26

<sup>17</sup> Ibid page 22

**33.15** Professor Ludlam was unable to recall specifically whether or not he discussed this question with any particular patient on an individual basis at that time. He thought it was possible that he did, since the issue had been raised in an interview with Dr Peter Kernoff (Director of the Haemophilia Centre at the Royal Free Hospital in London) entitled 'AIDS and haemophilia', reported in one of the Haemophilia Society Bulletins in 1983.<sup>18</sup> During that interview Dr Kernoff had been asked: 'should we stop using concentrates?' His response was:

[Y]ou have to realise that there's no treatment in medicine which doesn't have risks. In deciding to use a treatment, the risks have to be balanced against the benefits. I'm sure that you would agree with me that treatment with concentrates has massive benefits; and there's no doubt in my mind that the benefits far outweigh the possible risks. For people receiving regular treatment with concentrates, I see no reason to make any change from current practice. For particular patients, and at particular Centres, there may be reasons for preferring cryoprecipitate, but these reasons have little to do with AIDS.<sup>19</sup>

**33.16** Professor Ludlam said that if any of his patients had asked him about reducing the amount of concentrate (as distinct from changing to another form of therapy) he would have explained that his investigations into patients' immune systems (discussed below) had shown that there was nothing to suggest that using less concentrate resulted in a lower level of immune abnormalities.<sup>20</sup> By 1983–84, after the AIDS epidemic had been publicised, if a patient had said that they did not want Factor VIII he would have offered them cryoprecipitate. He would have told them, however, that he could not guarantee that cryoprecipitate was free of a putative AIDS agent and that if they wanted cryoprecipitate they would have to attend the hospital for treatment. He could not recall any conversation of that kind taking place.<sup>21</sup>

**33.17** Professor Ludlam said that he made extensive enquiries during 1983 amongst colleagues who might have seen patients with AIDS and people who might collect statistics on AIDS but that he could not find anyone who had any experience of having an individual they thought might have AIDS or who had a 'pre-AIDS' condition or 'AIDS-related complex' disease. At that time there was much less intercontinental air travel and movement of people and the population in Scotland was much more static than in North America or even England. Scotland had a very stable population of people with haemophilia but also he thought the general population was stable. For those reasons he thought the risks were small and that is what he said he told the patients if he spoke about the risk.<sup>22</sup>

### *Practice in Glasgow and south west Scotland: Glasgow Royal Infirmary*

#### **The evidence of patients at the GRI**

**33.18** The witness 'David', who gave evidence about the effects of his infection with HIV and HCV, was treated at the GRI. As detailed in Chapter 5, *An Examination of the Effects of Infection with HIV on the Patients and their Families, including Treatment*, at paragraph 5.171, he stated that he was not warned of risks of infection associated with

<sup>22</sup> Professor Ludlam – Day 35, pages 22–23

his haemophilia treatment, apart from 1984 when he recalled being warned about the risk of Hepatitis A infection.

### The evidence of Professor Forbes

**33.19** Professor Forbes told the Inquiry that very early on in the progress of the HIV/AIDS story he became aware that it was a blood-borne disease probably transmitted by Factor VIII, perhaps more readily by concentrates than by cryoprecipitate.<sup>23</sup> He was unable to recall an actual date for this realisation.<sup>24</sup> He said that, because there was an element of choice of therapeutic products available, he would always discuss with his patients what he was going to do in terms of treatment. He thought that the doctors in the Haemophilia Centre at the Glasgow Royal Infirmary (GRI) would always give patients what was considered the best advice which, at that time, was that cryoprecipitate should be used.<sup>25</sup> As detailed in Chapter 21, *Haemophilia Therapy – Use of Blood Products*, at paragraph 21.316 Professor Forbes frankly admitted that his recollection was not completely reliable. During his evidence, given the passage of time and despite his best intentions, Professor Forbes was often unable to recall specific matters and he spoke of his memory being ‘defective’ in certain respects.<sup>26</sup> The Inquiry established that use of cryoprecipitate at the GRI was a small proportion of concentrate use, whether of SNBTS origin only or of mixed SNBTS and commercial origin.<sup>27</sup>

**33.20** Professor Forbes said that by 1983 most people thought that AIDS would appear in the UK in due course and that he was already starting to look differently at his patients to see if they had any of the symptoms that might be an early warning of AIDS.<sup>28</sup> Although he could not now remember it, Professor Forbes attended the meeting at St Andrew’s House already referred to at paragraph 33.11. He thought that by March 1983 he knew enough to be concerned about AIDS but not enough, even from his knowledge of the US experience, to be clear about what precisely was happening. He described it as still ‘coming up on the horizon’ at that point.<sup>29</sup>

**33.21** Professor Forbes said that patients were very aware of AIDS because it was widely talked about in the media, ‘with some hysteria’, and there was ‘a lot of anxiety’ amongst the patients.<sup>30</sup> He said, however, that ‘the bottom line’ was that the patients needed to be treated; if they did not have treatment there was a real risk that they might die from bleeding. Up until the 1970s and into the 1980s, that was the usual problem. Not treating patients in order to protect them against the supposed danger of AIDS was not an option; they had to be treated and Professor Forbes felt that he had to choose what he considered to be the safest product from all points of view.<sup>31</sup>

**33.22** He said that he told patients about the risk of AIDS and advised them to continue with treatment.<sup>32</sup> He said that the ‘sensible ones’ agreed that they had to have treatment and were usually, but not always, given cryoprecipitate.<sup>33</sup>

<sup>23</sup> Professor Forbes’ statement on information given to patients [PEN.012.0411] at 0412

<sup>24</sup> Professor Forbes – Day 33, page 97

<sup>25</sup> Ibid page 104. The UKHCDO records of the use of blood products at the Glasgow Royal Infirmary between 1982 and 1985 indicate a relatively low use of cryoprecipitate, at about 15% of the total Factor VIII material used in each year.

<sup>32</sup> Ibid page 102

<sup>33</sup> Professor Forbes’ statement on information given to patients [PEN.012.0411] at 0412; Day 33, page 103

**33.23** Professor Forbes said that it was with some excitement that he heard that heat treatment of concentrates was a possibility in 1984. There was, however, a lot of concern about how effective this was and indeed one of the early heat-treated concentrates had transmitted virus, after which set-back it took some time to return to a degree of confidence in the heat treatment process.<sup>34</sup> As indicated in Chapter 21, use of commercial concentrate at the GRI was low in 1982, high in 1983 and very low in 1984. There was significant use in 1985 and that continued thereafter. By 1985 heat treatment of commercial Factor VIII was well established.

**33.24** It appears from his evidence that, at least initially, Professor Forbes did not discuss the possibility of using US heat-treated Factor VIII with his patients. When asked about this he said that he thought there was not enough evidence to say that the commercial heat-treated concentrates were totally safe. He also said that he was a little anxious that the heat treatment which was being proposed might in fact also destroy Factor VIII activity (the effectiveness of the concentrate to contribute to coagulation) and would make the treatment useless. That was certainly his personal view. It was only when clear evidence from studies came from the USA that he started to believe that effective heat treatment was a possibility.<sup>35</sup>

### The evidence of Professor Lowe

**33.25** Professor Gordon Lowe had relatively limited contact with haemophilia patients from 1983 to 1985 when he was on secondment to the NHS Medical Unit at the Glasgow Royal Infirmary.<sup>36</sup> He nevertheless kept an interest in haemophilia and continued to see haemophilia patients when he had the time, perhaps for a few hours a week, although he said that he saw few haemophilia patients at that time apart from treating occasional bleeds.<sup>37</sup> He said that there was increasing concern about AIDS in 1983 and 1984 and some patients did voice concerns about their treatment, but he could not recall any specific patients asking him about AIDS at that time.<sup>38</sup> He also could not recall whether he routinely raised the issue of AIDS with patients he saw.<sup>39</sup>

**33.26** Professor Lowe said that, in addition to telling the patients what he knew about the condition, he would have given them any educational material that was available and referred them to Professor Forbes or, prior to April 1983, Dr Colin Prentice (as the Director and Consultant) if they wanted more information.<sup>40</sup> He said that patients were always encouraged to ask if they had any questions about their treatment.<sup>41</sup>

**33.27** From May 1983 to December 1984 the Haemophilia Society produced a series of Bulletins and other publications on AIDS and haemophilia, including 'Haemofact' fact sheets, which provided information to patients.<sup>42</sup> Professor Lowe recalled that Professor Forbes arranged for these to be made available in the waiting room at the Haemophilia Centre and given to patients. The documents were distributed to patients, partners and families attending the Haemophilia Centre. They provided an update on the developing

information on AIDS; gave the consistent message that, while patients should balance the risks for themselves, Haemophilia Centre Directors continued to recommend factor concentrate therapy, because the advantages of treatment far outweighed any possible risk; they stressed that patients should discuss their personal position with their Haemophilia Centre Director.<sup>43</sup>

**33.28** Professor Lowe accepted that the best way for a doctor to give information to a patient about treatment and prognosis was for the doctor to give the information directly to the patient; that had always been his belief. He agreed that it would not be acceptable for a doctor to rely on a patient getting that information from another source such as the Haemophilia Society.<sup>44</sup> However, his assessment of the likely course of events in such a discussion remained hypothetical, since he did not recall any patient ever saying that they wanted to stop treatment. Nor did he recall any patient actually stopping their treatment.<sup>45</sup>

**33.29** He thought that during review clinics there would have been a discussion about the treatment that the patient was receiving at that time and that the patients would have been asked if they had any questions about their treatment, about hepatitis and, from 1983 onwards, about AIDS.<sup>46</sup>

**33.30** Professor Lowe told the Inquiry that if a patient had raised the issue of AIDS with him in 1983 he would have told them what he then knew about the condition: that some haemophilia patients in the United States had developed the condition; that it was possibly transmitted by blood products; that knowledge about the condition was emerging and there was a lot of research going on to try and find out what the explanation for it was. He said that, from memory, the main question that patients asked at that time was whether there had been any cases in Scotland or Britain. There had not been any reported until 1984.<sup>47</sup>

**33.31** Although there were a number of GRI protocols in place from the 1970s for the treatment of patients, Professor Lowe was unable to recall any specific protocol requiring junior doctors to initiate discussion with patients about the risk of AIDS.<sup>48</sup> It seems unlikely that any such written protocol existed. He was adamant that a major decision about a patient's treatment – for example, not taking treatment at all, reducing it or changing to a different type of treatment like cryoprecipitate – should be discussed with a Consultant and said that that remained the position right up until he became a Consultant in October 1985.<sup>49</sup> It continued even after then because Professor Forbes was the Director of the Haemophilia Centre and, as such, attended all the Haemophilia Directors' meetings and was intimately involved in all the research that was being undertaken. Professor Lowe said that, while he did his best to keep up with developments, he did not have the same level of expertise as Professor Forbes.<sup>50</sup>

**33.32** Having said that, he thought that most patients were very happy to talk through the risks and the benefits of treatment with him or any of the other junior doctors and take it from there.<sup>51</sup>

### *Practice in Glasgow and south west Scotland: Yorkhill*

#### The evidence regarding patients at Yorkhill

**33.33** The witness given the pseudonym 'Christine', who gave evidence about her son's infection with HIV, stated that she and her husband were not warned about the risk of infection with HIV or HCV. Her son was treated at Yorkhill until 1991 when his treatment was transferred to the GRI.

#### The evidence of clinicians: Professor Hann

**33.34** Professor Ian Hann's interests before moving to the Royal Hospital for Sick Children (Yorkhill) in 1983 had been in infections in patients with immune deficiencies and leukaemia and cancers associated with immune deficiencies.<sup>52</sup> Those interests had alerted him to the emerging AIDS epidemic in the United States in 1982 and clearly influenced his clinical response as information about AIDS emerged over time.

**33.35** As the new Haemophilia Director, Professor Hann inherited both stocks of therapeutic materials and a new constituency of patients to meet and become familiar with. He used up the limited existing stocks of commercial products at Yorkhill; thereafter, his treatment options were cryoprecipitate or SNBTS Factor VIII concentrate. This is reflected in the UKHCDO data on the use of clotting factors at Yorkhill over the period 1983 to 1985, as set out in Chapter 21, *Haemophilia Therapy – Use of Blood Products*, at paragraph 21.296 and Figure 21.9.

**33.36** Professor Hann said that, in response to AIDS, he and his colleagues made great efforts to speak to every single patient and offer them the possibility of stopping concentrate therapy and returning to cryoprecipitate treatment. Many patients attended the Centre regularly and he instituted a clinic and a parent support group where these issues were discussed. The Haemophilia Society was also putting out information at that time. He said that it was a matter of regret to him if some of the patients 'fell through the net' and had not been offered this change to their treatment.<sup>53</sup> Very young (and newly diagnosed) patients were usually managed as hospital-based patients.<sup>54</sup> They would be offered cryoprecipitate treatment in the first instance if it was logistically possible to give it to them (that is, if their veins were adequate and they did not have any reactions). Professor Hann said that cryoprecipitate treatment may even have been recommended as the first option for these patients in the difficult interim period.<sup>55</sup> That 'difficult interim period' lasted from May 1983 until late 1984 by which time the HTLV-III virus had been isolated and some of the patients were found upon testing to have antibody to the virus.<sup>56</sup>

**33.37** When he joined Yorkhill, most of the patients were already established on home therapy. He thought that it would have been extremely difficult, and unlikely to succeed, for home therapy to have been maintained with cryoprecipitate.<sup>57</sup> Cryoprecipitate treatment was not suitable for all patients, such as those with 'difficult veins' or those who experienced extreme allergic reactions. Professor Hann recalled that adverse reactions to cryoprecipitate, including life-threatening episodes of anaphylaxis, had been one of the

---

<sup>52</sup> See Chapter 9, *Knowledge of the Geographical Spread and Prevalence of HIV/AIDS 1*, paragraph 9.40

<sup>53</sup> Professor Hann – Day 31, page 27

<sup>54</sup> *Ibid* page 26

<sup>55</sup> Professor Hann – Day 21, pages 68–69

<sup>56</sup> Professor Hann – Day 31, pages 16–17

<sup>57</sup> Professor Hann's response to further questions from the Inquiry dated 13 April 2011 [PEN.012.0270] at 0271

reasons early attempts at establishing home treatment programmes with cryoprecipitate had been unsuccessful during the 1970s, before the introduction of factor concentrates. A return to cryoprecipitate treatment would have meant returning to hospital-based treatment and the lives of patients and their families would have changed dramatically as a result. Professor Hann recalled that the Haemophilia Society made similar observations around this time. For these reasons, most patients and families in the UK did not revert to cryoprecipitate treatment.<sup>58</sup>

**33.38** However, established patients at Yorkhill were given the option to switch to cryoprecipitate in 1983–84.<sup>59</sup> He thought that he and his colleagues would have discussed all possible therapies (including DDAVP) depending on the individual severity of the problem.<sup>60</sup> When asked whether he would have offered a child who was already receiving Factor VIII concentrate in late 1983 the possibility of ceasing concentrate therapy and returning to cryoprecipitate he said that he believed that was what they had in fact done at Yorkhill.<sup>61</sup> He said that he was almost certain that in late 1983 he did change some patients over to cryoprecipitate and that other patients, newly diagnosed or young children, remained on cryoprecipitate treatment for longer than would have been the case previously.<sup>62</sup> His recollection was that there were certainly patients in 1984 who returned to cryoprecipitate treatment for a period of time.<sup>63</sup> That is consistent with the record. UKHCDO data on product use show that use of cryoprecipitate at Yorkhill rose from 7050 units in 1982 to around 30,000 units a year from 1983 to 1985 inclusive.

**33.39** However, Professor Hann stressed that it was not a matter of automatically switching every child over to cryoprecipitate. Although there were suggestions in late 1983 – from Dr Peter Jones (Newcastle Haemophilia Centre) and the UKHCDO – that children should be treated with cryoprecipitate, the decision had to be tailored to each individual patient.<sup>64</sup>

**33.40** Professor Hann said that in early 1983 it was not clear what was causing AIDS and there was a great deal of doubt over whether it was going to become a real problem in haemophilia.<sup>65</sup> He thought that by that stage there had been reports of about eight or nine haemophilia patients who had developed AIDS in the USA; the first cases in the UK did not occur until later in 1983.<sup>66</sup> There were many meetings with other haemophilia directors during the year and his recollection was that it was not plainly obvious until the second half of 1983 that AIDS was an issue of blood product transmission in haemophilia care.<sup>67</sup> He said that it ‘sort of hit’ them later in the year that AIDS was going to be a ‘major issue’<sup>68</sup> and that it became clearer still later in 1983 or early 1984, when the first cases of AIDS were reported from Europe.<sup>69</sup>

<sup>69</sup> Ibid page 32. In fact, the first cases were reported from Europe earlier than this: see Chapter 9, *Knowledge of the Geographical Spread and Prevalence of HIV/AIDS 1*, paragraph 9.26.

**33.41** Professor Hann's approach to the provision of information was also illustrated in relation to new patients. He said that for those patients who were newly diagnosed with haemophilia he had a full discussion with their parents about the disorder and its treatment.<sup>70</sup> The main emphasis in discussion was on bleeds and how to avoid them. In addition, he would have explained what factor deficiency was, how it came about and the genetic aspect of the condition. Parents would have been told how to access the hospital social worker. There would also be a discussion about treatment, which included what it was, when it was required and what the potential side-effects were. He emphasised that the information would not be imparted in one interview; rather, the provision of information was seen as an ongoing process.<sup>71</sup> As well as the initial counselling of newly diagnosed patients, Professor Hann said that he had many discussions with patients following the initial descriptions of HIV transmission risks.<sup>72</sup> He could not recall exactly when these discussions would have taken place but thought that AIDS became a real issue during 1983.<sup>73</sup>

**33.42** He said that he would have explained what he knew at the time.<sup>74</sup> In 1983 he would have said that there had been a few cases of AIDS in haemophilia patients but that it appeared to be a 'rare risk'. He noted that even into 1984, after the prevalence of AIDS in Europe had been reported, experts like Peter Jones were quoting a transmission risk of one in 1200. He said that he hoped and believed that he and his colleagues were not just reassuring the parents but, rather, they were telling them that it was a possibility but that they did not know very much about it or what caused it.<sup>75</sup>

#### The evidence of clinicians: Dr Pettigrew

**33.43** Dr Anna Pettigrew started working at Yorkhill as a part-time Clinical Assistant in May 1980. She thought that she first became aware of the possibility that AIDS was caused by an agent transmitted by blood and blood products in 1983 but could not recall what triggered her awareness at that time.<sup>76</sup> Her recollection was that during 1983 there was a more reliable supply of SNBTS Factor VIII and the doctors at Yorkhill tried to encourage parents to use SNBTS concentrate rather than commercial concentrate.<sup>77</sup>

**33.44** As she recollected matters, the option of stopping factor concentrate altogether and moving back to cryoprecipitate was never raised with parents because of the impracticality of such a change. Dr Pettigrew said that a number of patients were established on home therapy treatment with Factor VIII concentrate before she started working at Yorkhill Hospital and before the risk of AIDS being transmitted through blood and blood products had been confirmed.<sup>78</sup> It would have been very difficult to institute home treatment with cryoprecipitate, although if parents asked about it then she would have discussed it with them.<sup>79</sup>

<sup>77</sup> Dr Pettigrew – Day 20, page 48. Use of SNBTS F.VIII in 1982 was 516,300 i.u. and of commercial concentrates 485,880 units. By 1984 SNBTS F.VIII use had risen to 1,035,396 units, with no commercial material purchased. The change was not a simple function of availability.

<sup>78</sup> Dr Pettigrew's statement on information to patients concerning HIV [PEN.012.0277]

<sup>79</sup> Dr Pettigrew – Day 20, pages 48–49

**33.45** She did not think that discussions about AIDS would necessarily have been recorded in the patient's medical notes because often parents called into the day bed area and she would not have had the child's notes with her. She said that she would only have had the child's notes if the child attended for medical advice or treatment.<sup>80</sup>

**33.46** When asked whether she would routinely discuss the risk of AIDS with parents even if they did not raise it themselves, she said that the majority of parents did voice concerns because they were a well-informed group and most of them were in contact with the Haemophilia Society and were therefore aware of the risk.<sup>81</sup>

**33.47** If parents voiced concerns, she told them that there was a possibility that AIDS was caused by an agent transmitted by blood but that there was no definite proof at that time. There was still a lot of debate, even among the experts, as to whether or not there was definitely an infectious agent and the advice at that time was that they should continue with therapy. She said that she would have been following the advice of her seniors at that time.<sup>82</sup> She could not recall any specific policy regarding discussing the risk of AIDS with parents.<sup>83</sup>

**33.48** She could not recall giving initial counselling to parents of newly diagnosed haemophilia patients, although she did sometimes attend such appointments. The Consultant would normally have a full discussion with parents at this time, with the main aim of these initial meetings being to ensure that the parents understood the risk of bleeding episodes. Her recollection of the meetings that she attended was that Professor Hann would recommend concentrate therapy unless the parents specifically stated that they did not want it, in which case their wishes would have been respected. She did not think that any parents did so.<sup>84</sup>

### The evidence of clinicians: Sister Christine Murphy

**33.49** Sister Christine Murphy provided evidence in a written statement. She began working in the Haemophilia Department as a part-time staff nurse in September 1983.<sup>85</sup> She told the Inquiry that when she started working at Yorkhill there was no talk about HIV although Hepatitis B was spoken about and the children were being tested for that. She said that she presumed the parents had been warned about the risks of Hepatitis B. She thought it was 1984 or into 1985 when HIV was discussed, when it appeared in the press.<sup>86</sup>

**33.50** She said that Scottish Factor VIII was used when she worked at Yorkhill. Although there was 'a bit of panic to start with about the blood products', it was explained to the parents what would happen to their child if they did not use the blood products.<sup>87</sup> She could not recall the exact words that were used but the parents were advised of the consequences of leaving bleeds untreated. They would be informed that joints could suffer irreparable damage and that any internal injuries or head injuries could be life-threatening, depending on their severity. They were also told that untreated bleeds would most likely cause problems later in life, although most parents already knew this.<sup>88</sup>

<sup>86</sup> Ibid [PEN.018.1149] at 1151–52

<sup>87</sup> Ibid [PEN.018.1149] at 1153

<sup>88</sup> Ibid

**33.51** She recalled that at one point one of the parents had their child put back onto cryoprecipitate rather than Factor VIII as at that point in time the parent felt that cryoprecipitate was safer. The child had severe haemophilia so had to have some treatment for bleeds. Eventually the child was returned to Factor VIII, on the commencement of heat treatment of blood products.<sup>89</sup>

### *The wider context*

#### **AIDS and the Haemophilia Society**

**33.52** The Haemophilia Society performed two important functions in this context: it collected intelligence and data relating to what was happening to its members and it obtained and published the views and advice of medical experts. The Society was not responsible for the validity of the expert medical advice published in newsletters and fact sheets and it has to be emphasised that in narrating the evidence that follows, the Society is properly to be seen as a reporter of others' views and advice. However, what the Society put into the public domain inevitably bore the stamp of its authority among its members and helped set the context for their understanding of their condition and their expectations of the clinicians advising and treating them.

**33.53** For present purposes, it is sufficient to note events from May 1983. The first article published by the Society which provided information on AIDS, by Dr Anthony J Pinching, a noted pioneering AIDS clinician from London, appeared in *Haemophilia Society Bulletin* 2, 1983.<sup>90</sup> In the same issue, comments by Professor Bloom in a talk given to the Annual General Meeting of the Haemophilia Society in April 1983 were quoted. In respect of AIDS, he said:

I cannot end without a comment on one new problem which may turn out to be the greatest myth or the most significant reality of all.<sup>91</sup>

**33.54** Professor Bloom was then Honorary Director of the Cardiff Haemophilia Centre and Chairman of the UK Haemophilia Centre Doctors Organisation. His remarks provide a clear illustration of the extent of the uncertainty about the significance of AIDS within the medical community and, consequently, for the Society's members.

**33.55** Professor Bloom underlined his opinion in a letter he wrote in response to what had been seen as unduly alarmist reports on AIDS in the media. The letter, which was published by the Society on 4 May, contained the comment that:

[I]t is important to consider the facts concerning AIDS and haemophilia. The cause of AIDS is quite unknown and it has not been proven to result from transmission of a specific infective agent in blood products .... [W]hilst it would be wrong to be complacent it would equally be counter-productive to alter our treatment programmes radically. We should avoid precipitate action and give those experts who are responsible a chance continually to assess the situation.<sup>92</sup>

---

<sup>89</sup> Ibid

<sup>90</sup> *The Bulletin*, 1983 No. 2, The Haemophilia Society [PEN.016.0607] at 0617

<sup>91</sup> Ibid [PEN.016.0607] at 0608

<sup>92</sup> Professor Bloom's letter, issued by the Haemophilia Society, 4 May 1983 [DHF.001.4474]

**33.56** Leaving aside the media comments that had prompted the Society to approach Professor Bloom,<sup>93</sup> Mr David Watters, General Secretary of the Society between 1986 and 1994 (and Coordinator for five years before that), explained that the Society's letter was intended to reassure members that there were no known cases of AIDS in the UK haemophilia population. He was confident that the letter had been circulated in draft to members of the Society's medical advisory panel. No one expressed dissent from what was said in the letter.<sup>94</sup>

**33.57** Dr Frank Boulton, a former Deputy Director of the SEBTS who had a long and distinguished career in haematology in both Scotland and England, proposed a theory to explain the Haemophilia Society's preference for continued use of existing therapy, which included commercial products. He said:

[A]t that time, the early 1980s, I think it would be fair to say that the Haemophilia Society was very reluctant to accept the validity – they wanted the risk of nasty things from their blood products to be really proved before they would agree to reducing the availability of material for their patients.

So there was a drive from the haemophiliacs themselves, including the Haemophilia Society, to maintain the amounts of therapeutic material available.

So there was, in other words, a feeling that the risk was probably acceptable.<sup>95</sup>

**33.58** An excerpt from the transcript of his evidence was read out to Mr Watters who commented that what Dr Boulton said sounded reasonable.<sup>96</sup> He added:

I think that what he says is not too different from the attitude taken by both the Haemophilia Society and by the medical advisory panel of the Haemophilia Society. That is that people with haemophilia and the Society and the treaters were in a very difficult situation and they could either decide not to treat patients or to continue treating patients because there was no magic solution, and as such they took the judgment in the light of knowledge in those days – not in the light of knowledge in 2012 but in the light of knowledge available at that time – that it would be best to continue to treat with imported plasma products.<sup>97</sup>

**33.59** A similar view was taken by haemophilia clinicians. The Haemophilia Reference Centre Directors met on 13 May 1983 to discuss AIDS.<sup>98</sup> By that stage, as they understood it, there was one suspected case of a haemophilia patient suffering from AIDS in the UK. The importance of immediate reporting of any suspected cases was stressed so that the clinical course of the patient could be followed and a definitive diagnosis of AIDS attached if the patient developed intractable disease, at that time the sole criterion for a positive diagnosis in the UK (applying the definition of AIDS adopted by the US Centers for Disease Control). General treatment policy was discussed and it was agreed that there was, at that point, insufficient evidence to warrant restriction of the use of imported concentrates in patients other than children and mildly affected haemophilia patients, in view of the immense benefits of therapy.

<sup>97</sup> Mr Watters – Day 87, page 109

<sup>98</sup> Minutes of Special Meeting of Haemophilia Reference Centre Directors, 13 May 1983 [DHF.001.4384]

**33.60** The Haemophilia Society's medical panel and the Reference Centre Directors collectively represented the views of senior, and eminent, UK haemophilia clinicians. Other experts may have taken different views, as noted below, but a balanced assessment of the position was given by Professor Andrew Lever. He emphasised that around mid-1983 there were competing hypotheses as to the cause of acquired immunodeficiency in patients, some of which had powerful advocates. He thought that the balance of evidence at that stage was in favour of an infectious agent.<sup>99</sup> He continued:

However, as one knows, the amount of distress and concern and worry, sometimes unnecessarily, that you can induce in people by raising the fear of an infectious agent in something like a blood product would be undesirable unless it was absolutely the case, or as near certain as you could be that that was the case.

I think people would not necessarily have been very understanding had this turned out to be a false alarm and individuals had either bled or died by withdrawal of the clotting factors and then it having been found that there was not the threat which had been assumed.<sup>100</sup>

### The evidence of Dr Winter

**33.61** Some haemophilia clinicians took the same view of the cause of AIDS as Professor Lever. Dr Mark Winter discussed his experience in England. He was appointed Consultant Haematologist at the Canterbury and Thanet Health Authority in 1983, and thereafter managed haemophilia patients throughout his career. In 1984 he was designated HIV physician for the area and was responsible for all patients who had AIDS. For the rest of his career he specialised in AIDS. He was also the medical officer appointed by the Department of Health (DoH) to serve on the MacFarlane Trust and the Eileen Trust.<sup>101</sup>

**33.62** With this background, Dr Winter was in a position to speak from first-hand experience about developments in the response to AIDS during the reference period. His contact with haemophilia patients had begun before 1983 while he was a Senior Registrar at Guy's Hospital, London where he discussed with his patients the risk of contracting the new virus. He would explain that there were worrying data which suggested that a new virus might be transmitted by concentrates but that, on balance, the advice was to continue with treatment because the risk of giving up treatment was greater.<sup>102</sup>

**33.63** Due to policy decisions in England and Wales, Dr Winter did not have ready access to NHS concentrates in his Kent centre, and largely had to rely upon licensed commercial concentrates of US origin.<sup>103</sup> By 1984 he and his colleague, Professor Savidge (St Thomas' hospital) had concluded that NHS Factor VIII concentrates not only transmitted NANB Hepatitis but also probably contained the new virus.<sup>104</sup> In May 1984 heat-treated concentrate from the USA became available on a named patient basis and he managed to obtain a small supply of the product.<sup>105</sup> The heat treatment was intended to destroy viruses including

---

<sup>99</sup> Professor Lever noted that by this stage HTLV-I had been implicated in human disease, targeting lymphocytes; that AIDS was associated with dysfunction of the lymphocytes; and that there were similarities in epidemiology, among factors suggesting an infectious aetiology.

<sup>105</sup> Dr Winter – Day 16, page 107

NANB Hepatitis and HIV. That same month, he approached a small number of patients with mild haemophilia who required major surgery, or who had suffered acute trauma, and had received little or no Factor VIII concentrate in the past. He offered them a choice between the currently available licensed, unheated NHS concentrate, prepared from voluntary donations, or the new, unlicensed, heat-treated Alpha Therapeutics concentrate prepared from paid donations.<sup>106</sup> He advised his patients to take the new American product in preference to the licensed, unheated US product and the unheated NHS concentrate.<sup>107</sup>

**33.64** He described it as an especially critical and difficult time because patients were being asked to switch from concentrate of UK origin to concentrate of US origin which they had always distrusted. He told the Inquiry that considerable time had to be spent with each patient and their family to explain the basis of this recommendation.<sup>108</sup> He thought that he would have spent about half an hour with each patient.<sup>109</sup>

**33.65** During these meetings he conveyed the following information to the patients:

- There was increasing evidence that AIDS could be transmitted through the use of Factor VIII concentrate which was a matter of growing concern.
- There was a new type of Factor VIII concentrate which was heat-treated and therefore in theory might inactivate the (very recently discovered) virus that caused AIDS. There was however no proof of this at that stage.
- There was strong evidence that patients were likely to get hepatitis from unheated NHS Factor VIII concentrate if they did not already have it and that it might also contain the new virus that was causing AIDS.
- The new heat-treated commercial Factor VIII was designed to inactivate hepatitis viruses.
- The new heat-treated commercial Factor VIII came from US blood donors and was not licensed in the UK.<sup>110</sup>

**33.66** Many of the patients he approached instinctively resisted his advice, relying on their long-held belief that UK concentrates were safer than US concentrates. In the event, all agreed to the use of the heat-treated product.<sup>111</sup> By July 1984 he was able to get sufficient supplies of the heat-treated Factor VIII and the heat-treated Factor IX, to switch all of his haemophilia patients to whichever product they required. From 1 July 1984 the St Thomas' centre and Dr Winter's centre in Kent used, exclusively, heat-treated concentrate.<sup>112</sup>

**33.67** On the evidence available to the Inquiry, the practice described by Dr Winter was followed in a few centres only. The majority of treating doctors in the UK in 1984 continued using unheated NHS Factor VIII rather than switching to imported, heat-treated commercial Factor VIII. Dr Winter said that to the best of his knowledge, only the centres in Sheffield, University College Hospital, St Thomas' and Canterbury made the decision to switch to heat-treated commercial Factor VIII in May 1984. The decision was criticised at this time at meetings of the UKHCDO by other Directors who thought that viral transmission of the HIV/AIDS virus through the use of concentrate derived from voluntary UK donors was unlikely.<sup>113</sup>

<sup>113</sup> Dr Winter's statement [PEN.015.0292] at 0299

**33.68** In his evidence Dr Winter noted<sup>114</sup> that what he did was contrary to what Professor Bloom had said a year earlier in the letter of 24 June 1983<sup>115</sup> about heat-treated commercial product.

#### Developing UKHCDO advice: 1984

**33.69** The UKHCDO response to imported heat-treated Factor VIII had, meantime, moved forward. On 29 March 1984, Professor Bloom sent a memorandum to all UK Haemophilia Centre Directors advising on the appropriate response to proposals by commercial companies to trial new heat-treated products.<sup>116</sup> The memorandum listed different types of Factor VIII concentrate available for trial at that time, with another about to become available:

- (1) Heated products from Armour, Cutter, Travenol and Alpha Therapeutics. The three former are 'dry heat' preparations and the latter (Alpha Therapeutics) is a wet heat product.
- (2) NHS factor VIII prepared from a specially selected donor panel which is monitored for abnormal LFT's, hepatitis etc.
- (3) Heated NHS factor VIII; one brand is manufactured at the PFC in Edinburgh and will be shortly available. The second, manufactured at Elstree, should be available later this year.
- (4) A heated preparation manufactured by Behringwerke ....<sup>117</sup>

**33.70** The memorandum noted that clinical trials had already been completed on one product, the 'Hemofil HT' Factor VIII concentrate which was prepared using a dry heat method. The results indicated that there was still a 63% attack rate of NANB Hepatitis on first exposure in patients who had not received Factor VIII concentrate previously. The memorandum also noted that all products except those derived from NHS Factor VIII were made from plasma imported from the USA and therefore carried a putative risk of transmission of AIDS. The memorandum did not comment on the approach to be adopted in dealing with patients who might be appropriate subjects for clinical trials. That was left to individual practitioners.

**33.71** Professor Ludlam was not willing to participate in the trials<sup>118</sup> as he thought that there was nothing to be lost and the possibility of a lot to be gained by not using the heat-treated product.<sup>119</sup> Professor Ludlam told the Inquiry that he did not discuss the possibility of using heat-treated commercial Factor VIII (as part of a clinical trial or on a named patient basis) with his patients because he did not think it was in their best interests. He considered that not only would the trials have exposed them to concentrate that was likely to contain hepatitis, but also the product was derived from a donor population that appeared to have HTLV-III and at that stage there was no evidence that heat treatment would inactivate it.<sup>120</sup> Effectively, therefore, Professor Ludlam took the opposite view to Dr Winter at this time. The Inquiry recognises the logic of each position in its context.

## Haemophilia Society publications 1984–85

**33.72** Haemophilia Society publications continued to provide information and advice on treatment, backed by eminent practitioners. In Bulletin 1, 1984, K E Milne wrote:

We have no evidence as yet to whether AIDS may be acquired more readily from commercial Factor VIII than from the NHS product but, of course, if AIDS becomes established in the UK then NHS blood and plasma supplies are just as likely to transmit AIDS as commercial materials. All things considered, haemophiliacs have no reason to be worried about using commercial concentrates.<sup>121</sup>

**33.73** Having regard to the date of publication, and Dr Winter's evidence about supply, this was probably written shortly before the first heat-treated products began to be available. The comment was sustainable only on the assumption that there was no choice whether to have therapy and that the sole question was which form to use. That was a universally held assumption amongst clinicians at the time.

**33.74** It was reflected in the views of haemophilia staff and of the mothers of haemophilia patients when they were expressed in Bulletin 1 of 1985:

All blood products cannot be guaranteed free of the viruses associated with hepatitis and other disorders such as AIDS. However, the minimal risks associated with this treatment are in our opinion outweighed by the advantages of using these products which ensure our children do not grow up crippled.<sup>122</sup>

## Product inserts

**33.75** In the course of the Oral Hearings there was discussion of the function of the leaflets containing information on risks of concentrates, which leaflets were prepared by the SNBTS and issued with products manufactured by the PFC, Liberton.<sup>123</sup> The information was brief and, if it had been directed to patients, was less than comprehensive. A series of questions specific to HIV/AIDS were drafted by Messrs Thompsons for answer by Dr Robert (Bob) Perry relating generally to the period 1982–85. In this part of the discussion, it is appropriate to deal with the period to 1984.

**33.76** Dr Perry explained that the formal product documentation issued by the SNBTS was prescribed by regulatory standards and pharmacopoeia monographs in force at the time. He referred to the British Pharmacopoeia Monograph on dried Factor VIII fraction.<sup>124</sup> The leaflets were included in the packages issued to patients, especially those on home treatment. However, at the material time, manufacturers were not permitted or expected to engage in direct contact with patients.<sup>125</sup> Until 1984 the regulatory requirement was for Technical Information Labels only and the SNBTS leaflets were directed at health care professionals and were primarily intended for prescribing doctors.<sup>126</sup> Until 1984 (and indeed later), the leaflets were not an appropriate vehicle for providing information to

<sup>124</sup> Dr Perry's statement in response to questions on SNBTS package inserts [PEN.018.0543] at 0547

<sup>125</sup> *Ibid* [PEN.018.0543] at 0544; Dr Perry – Day 38, pages 95–96. The position changed in 1994 when Patient Information Leaflets became a legal requirement.

<sup>126</sup> Dr Perry's statement in response to questions on SNBTS package inserts [PEN.018.0543] at 0544

patients and were not prepared for that purpose.<sup>127</sup> In 1994 it became a legal requirement to provide product information leaflets specifically for patients. The SNBTS then issued appropriate patient information with PFC products.<sup>128</sup>

**33.77** While this necessarily limited Dr Perry's attempts to answer the specific questions drafted by Messrs Thompsons, the questions were important to the patient core participants and it is appropriate to set out his evidence. The questions specific to HIV/AIDS related to:

- Discussions between staff about the possibility of including reference to the risk of HIV transmission on package inserts included with factor concentrates between 1982 and 1985.
- Why and by whom it was decided that there should be no reference to the risk of HIV transmission in PFC factor concentrate package inserts between 1982 and 1985.
- From whom the PFC staff took advice about the risks of transmission of HIV via PFC concentrates between 1982 and 1985.
- The advice given to the PFC over that time period about the risk of HIV transmission from PFC factor concentrates.
- Whether there was awareness within the PFC of the fact that US products had such warnings on their inserts from around October 1983.
- To what extent such awareness impacted upon the attitudes of PFC staff to include such a warning on their factor concentrate inserts.

**33.78** The virus, originally LAV/HTLV-III and renamed HIV in 1986, was not generally understood to be the causal agent of AIDS until Dr Gallo announced in the spring of 1984 that he had discovered the virus.<sup>129</sup> Consequently, the relevant period begins, at the earliest in the spring of 1984. Dr Perry's attempt to answer the first question in terms was not productive. He could not recall if he discussed the possibility of including HIV warnings in PFC product inserts with Mr Watt, the PFC Director in 1982 and 1983, and he did not know if Mr Watt had discussed that possibility with any others at the SNBTS.<sup>130</sup> Dr Perry led a review of packaging systems for PFC Factor VIII and IX in 1982–83 but product warnings remained unchanged.<sup>131</sup>

**33.79** In answer to the second question, Dr Perry said that he had been advised by Dr Peter Foster that the inclusion of such an HIV warning had been rejected at a meeting in 1983. The SNBTS has found no record of this.<sup>132</sup> Dr Perry pointed out that PFC products were produced for use by a small group of haemophilia doctors who were well informed about the situation concerning AIDS. He expressed the view that the amendment by the SNBTS of its product leaflet to include an unquantifiable risk warning would have done little to enhance doctors' knowledge or their communications and discussions with patients, especially as the topic of AIDS was being widely discussed by haemophilia doctors.<sup>133</sup> The Inquiry subsequently took statements from Dr Foster and Professor John Cash on this point.

---

<sup>127</sup> Inevitably some witnesses read the leaflets as if they were addressed to patients. However, criticism of their terms on that basis was misconceived.

<sup>128</sup> Dr Perry's statement in response to questions on SNBTS package inserts [PEN.018.0543] at 0544

<sup>129</sup> As discussed in Chapter 9 *Knowledge of the Geographical Spread and Prevalence of HIV/AIDS 1*, Montagnier's discovery of LAV in 1983 was not widely recognised at the time.

<sup>130</sup> Dr Perry's statement in response to questions on SNBTS package inserts [PEN.018.0543] at 0544

<sup>131</sup> *Ibid* [PEN.018.0543] at 0545

<sup>132</sup> *Ibid*

<sup>133</sup> *Ibid* [PEN.018.0543] at 0546

**33.80** In his statement, Dr Foster said that he remembered attending a meeting on 14 November 1983<sup>134</sup> when Professor Cash proposed that a product warning about AIDS should be added to the leaflets issued with PFC concentrates. However the haemophilia doctors were generally against that proposal because such a warning would cause ‘unnecessary anxiety to patients’. He also stated that the Haemophilia Directors believed that there was little or no risk of AIDS being transmitted by PFC products.<sup>135</sup> In his statement<sup>136</sup> Professor Cash agreed in general terms with the recollections of Dr Perry and Dr Foster but recalled that his proposal had, in fact, referred to hepatitis warnings rather than to AIDS. He thought that after one of his trips to Australia he proposed that a hepatitis risk warning should be included. The proposal did not enjoy much support and a legal opinion was sought by Jim Donald (CSA General Manager). No risk warning was included.

**33.81** Dr Perry explained that the PFC did revise its product leaflets in April 1985 when FVIII NY (Factor VIII heat-treated at 68°C for 24 hours) was introduced. The revised leaflet and package label stated: ‘the freeze dried product has been heat treated but cannot be assumed to be non infective’. He explained that the term ‘non-infective’ was intended to encompass all potential blood-borne infections, including HIV/AIDS. In addition, when the new heat-treated Factor IX product, DEFIX, was issued in October 1985 it stated:

In addition, product, plasma pools and individual donations are tested for the presence of antibody to HTLVIII. The product has been heat treated at 80°C for 72 hours in the freeze dried state. This treatment is expected to inactivate viruses associated with the Acquired Immune Deficiency Syndrome.<sup>137</sup>

**33.82** Dr Perry explained that he had been unable to find any evidence of a process whereby individuals had discussed the merits of the introduction of AIDS warnings. Prior to 1985, product information supplied by the PFC/SNBTS reflected the background of knowledge and guidance available between 1982 and 1984. He stressed that, prior to 1984, there was no consensus on a causal relationship between AIDS and treatment with coagulation factor concentrates. The inclusion of such warnings in product literature required some measure of evidence that a genuine risk existed. The inclusion of warnings could cause anxiety to patients who may have read the leaflets and might have caused them to reject life-saving treatment.<sup>138</sup>

**33.83** In answer to the fourth point, Dr Perry explained that there were various discussions and meetings involving the SNBTS and government health departments and other regulatory bodies but he did not recall that this produced any guidance or advice. The PFC maintained an awareness of international developments through its network of professional and scientific contacts and regular discussions with haemophilia directors and SNBTS experts such as Dr Boulton and Professor Cash.<sup>139</sup>

**33.84** Dr Perry mentioned that an application for a licence for the PFC product FVIIIINNY made in 1983 to the Committee on the Safety of Medicines included a product insert leaflet which made no mention of HIV or AIDS. The application was approved. He considered that this indicated that the Committee did not expect leaflets issued with

<sup>136</sup> Professor Cash's response to Dr Perry's statement [PEN.018.1145]

<sup>137</sup> Dr Perry's statement in response to questions on SNBTS package inserts [PEN.018.0543] at 0545

<sup>138</sup> Ibid [PEN.018.0543] at 0546

<sup>139</sup> Ibid [PEN.018.0543] at 0547

plasma products derived from UK donors to carry warnings about AIDS. He stated that 'The PFC received no subsequent request or advice from the Licensing Authority ... to include AIDS warnings'.<sup>140</sup>

**33.85** Dr Perry did not recall the PFC receiving any specific advice or guidance concerning the risk of transmission of HIV/AIDS by its products. Even with the benefit of hindsight, he thought it was difficult to identify what advice could have been given to the PFC which could have been translated into warning statements.<sup>141</sup>

**33.86** In relation to North America, Dr Perry's attention was drawn to a passage from page 399 of the Report of the Commission of Inquiry on the blood systems in Canada (the Krever Commission) which mentioned that US fractionators included warnings about the risk of AIDS to the information in the product inserts.<sup>142</sup>

**33.87** Dr Perry commented that the quotation related to concentrates prepared from plasma collected in the USA. Page 400 of the Krever report noted that, although Cutter Laboratories did include warnings with its products prepared from US plasma, it did not provide such warnings in 1984–85 with products derived from plasma collected in Canada. Dr Perry suggested that the fact that the same company was adopting different positions in relation to the origin of the plasma indicated that the risk of AIDS was still considered to be primarily associated at that time with plasma collected in the USA from paid donors.<sup>143</sup>

**33.88** He explained that, although product literature from commercial companies was periodically received at the PFC, he was unable to recollect the extent to which these documents would have been examined at the time, either by him or other senior PFC colleagues. He would have been aware that products carried warnings of product infectivity but he could not recall if he was aware of specific AIDS or HTLV-III warnings.<sup>144</sup>

**33.89** He said he had been unable to find evidence for the precise time when mandatory AIDS warnings were universally required. His understanding was that different manufacturers adopted them at different times. He explained that when it became clear, in October 1984, that there was a risk from SNBTS products, 'we quickly issued heated NY product (68°/2hr) and subsequently modified the leaflet for inclusion with the later FVIII product (NY 68°/24hr)'.<sup>145</sup>

**33.90** In answer to the final question, Dr Perry responded that he could not recall any discussions amongst PFC staff, or with Professor Cash or Dr Boulton, concerning the introduction of AIDS warnings in PFC product inserts. He believed that the general view held by the PFC, the SNBTS and the Haemophilia Directors was that the epidemiology of AIDS in the US, and particularly amongst US paid donors, was quite different from that in the UK.<sup>146</sup>

**33.91** Dr Perry provided evidence on information leaflets enclosed in packages of PFC products from 1978. The exploration of these questions has not provided the Inquiry with relevant information on the topic of communications with patients and their families in

<sup>146</sup> Ibid [PEN.018.0543] at 0550

relation to HIV/AIDS save in one respect. It is clear from the evidence of Dr Foster, Professor Cash and Dr Perry that, notwithstanding that there was no legal requirement, SNBTS officers discussed modification of the information documents to include warnings related to AIDS (and additional warnings related to hepatitis). Discussions in 1983 were clearly influenced by the views of haemophilia clinicians. Their views primarily reflected their own understanding of risk and their practice in relation to the provision of information, and have been dealt with in the course of this chapter. The concerns expressed were substantially those identified by Professor Lever in paragraph 33.60.

**33.92** So far as the questions posed relate to the provision of information to patients about risks of transmission of HIV, the contents of the SNBTS product inserts do not raise, or provide a focus for, new issues relating to clinical practice in the period to 1984.

### **The testing of patients' blood samples**

**33.93** Two specific issues of some importance arise in relation to the testing of haemophilia patients' blood samples in the period to 1984. The first of these relates to studies carried out in Glasgow and Edinburgh of changes in the immune functions of patients receiving concentrate therapy. Questions arise whether the studies were directly associated with patient management (in which case they might at some stages in developing ethical theory have been considered to be 'therapeutic' research) or were research studies more broadly defined that required ethical consent from an appropriate regulatory research body, and in either case whether patient consent to the use of their blood was required. The second issue relates to testing carried out on stored samples of patients' blood or serum in the late autumn of 1984 following the development of the first assays for anti-HTLV-III. The question arises whether patient consent was required for these tests. There are then consequential questions that extend over some years following the receipt of the results of the tests that relate to the communication of test results to patients and the information and advice that was appropriate in the light of individual patients' results. To set the context for the discussion, it is necessary first to discuss practice relating to the routine testing of patients' blood over the period to 1984.

#### ***Routine blood tests to 1984: practice in Scotland***

**33.94** Throughout the material period, routine testing of coagulation disorder patients' blood for identifiable infections and for biometric indications of the progression of their primary condition and of possible infections was common in Scotland, as elsewhere, as an aspect of patients' general management. Use of stored samples of haemophilia patients' blood for comparison, or to enable a full assessment of a patient's condition to be made and reviewed, was routine.

**33.95** Testing procedures were not static throughout the period, however. Routine testing inevitably changed as knowledge of the natural history of infectious diseases and of the risks of transmission of infection increased. Similarly, the technology available to assess risks and to respond to the implications for patients improved throughout this period. It is important to bear this background in mind as doctors were confronted by what were clearly, with the benefit of hindsight, new risks of transmission of viral infection and by the technology developed to identify and respond to those risks. In an ever-changing environment of therapy and patient management, what is truly new, requiring a step change in practice, may not necessarily appear so at first sight. In this, as in other areas, the scope for variation in clinical practice makes it necessary to look at practices in individual centres separately.

## Edinburgh and south east Scotland

**33.96** Professor Ludlam said that the Edinburgh Haemophilia Centre had a long tradition, starting in the 1960s and 1970s, of systematically studying the bleeding patterns of patients with haemophilia. It was among the first centres to assess hepatitis infection and the risks of virus transmission with the initial studies on Hepatitis B virus (HBV) infection.<sup>147</sup> Blood was taken for testing when patients attended at review clinics for scheduled sessions, for out-patient treatment of acute bleeds, or when patients had been admitted to hospital. While not necessarily carried out on every attendance, taking blood samples for testing was a routine procedure associated with what became the long-term systematic assessment of the viral safety of treatment. Testing of samples to monitor patients' conditions was carried out in a laboratory in the Department of Haematology.<sup>148</sup>

**33.97** The frequency of a patient's attendances depended on their clinical situation. For example, in the early 1980s, when cryoprecipitate was generally used in treating patients at the hospital, those with severe haemophilia might attend the treatment room two or three times a week where they would be seen, reviewed and treated. If they had not been reviewed for a while or if there was something unusual about their clinical state, blood samples would be taken for review or to investigate why they were unwell.<sup>149</sup> Other patients, such as those on home treatment, might only be seen for review every three or four months provided there were no problems. Part of their regular review would involve taking blood samples for routine monitoring.<sup>150</sup>

**33.98** Professor Ludlam explained the routine for taking blood. About a tablespoon of blood (15 millilitres) was taken.<sup>151</sup> Although not a great quantity of blood, the procedure was nonetheless significant: the patient understood the process although perhaps not the precise range of tests then carried out. Professor Ludlam said that a sample would be taken for a full blood count, assessment of blood chemistry (for example, urea and electrolytes and liver function tests), assessment for the presence of inhibitors (resistance to Factor VIII treatment) and assessment for viral infection.<sup>152</sup> He said:

It was important to make sure that the patient's haemoglobin and white [cell] count and platelets were in the normal range .... [O]ne of the complications, particularly of the early Factor VIII concentrates, was they contained antibodies to red cells and so you could get destruction of the red cells and hence anaemia.

The other reason for checking the haemoglobin was that sometimes patients had silent bleeding into their gastrointestinal tract. That was not uncommon. So this was a way of being alerted to that possibility.<sup>153</sup>

---

<sup>147</sup> Professor Ludlam's note on long term safety monitoring for transfusion-transmitted infections [PEN.012.0351]. These practices probably began under Professor Ludlam's predecessor, Dr Davies; see Professor Ludlam's note on the development of the Edinburgh Haemophilia and Thrombosis Centre [PEN.012.0386] at 0395

<sup>152</sup> Professor Ludlam's note on long term safety monitoring for transfusion-transmitted infections [PEN.012.0351]

<sup>153</sup> Professor Ludlam – Day 35, pages 5–6

**33.99** At the laboratory a full blood count of the different types of cells in the patient's blood was carried out. This was a useful test for providing an overview of a patient's general state of health.<sup>154</sup> Testing monitored the patient's total white cell count and the number of different white cells (polymorphs, eosinophils, monocytes and lymphocytes) in the samples. These measurements were routinely made and recorded without reference to the patient for consent.

**33.100** Professor Ludlam said that in the 1980s he did not obtain explicit consent from his patients for each individual test.<sup>155</sup> At that time he relied on implied consent. When a patient came for their routine visit they were used to having blood taken for tests that were deemed to be necessary for monitoring their health.<sup>156</sup> It is very likely that the same practice was followed in many clinics, and for many diseases, throughout the UK at that time. He stated that his practice in this regard had changed (as indeed it had for medical practitioners generally):

I did not go through each individual investigation, like I think I would now. Times have changed and I would [now] very clearly go through [and] list the tests in the case notes and make a note that the patient agreed to these investigations.<sup>157</sup>

#### **Practice in Glasgow and south west Scotland: the Glasgow Royal Infirmary**

**33.101** Practice at the GRI was similar to that in Edinburgh: monitoring blood tests were undertaken as part of routine attendance at the clinic. Blood samples for monitoring were also taken from patients attending for treatment of acute bleeds and from patients who had been admitted to hospital.

**33.102** Professor Forbes said that from about 1987 patients were asked for specific consent before testing but that often before that time they were not. In his experience, seeking consent to carry out tests came in gradually.<sup>158</sup>

**33.103** When asked what obtaining specific consent involved he said:

I think the important thing is that you are telling patients what is going to happen and why it's to happen and to ask their consent for it to happen. This was very much a change in the ethos of medicine. Until then the implication was that if you went to a doctor with a problem, he would do his best to find the cause of it, without asking your consent for blood samples or whatever, and that was how things were at that time.

I'm not saying that's the right thing because I think that now clearly it is not the right thing, and I think that before one does very much to people, there has to be implied consent and if you are doing anything invasive, like blood samples or endoscopy, you actually have to tell them exactly what you are doing, what it will find for them and what you can do about it and that is implied [sic – specific] consent and often [it] is now written down and that is certainly safer.<sup>159</sup>

<sup>159</sup> Professor Forbes – Day 33, pages 123–124

**33.104** At the material time for present purposes, up to 1984, there was clearly no practice of obtaining patient consent to any specific tests carried out on the blood taken from patients on a routine basis in the centres in Edinburgh and the GRI.

*Immunological studies: Edinburgh and south east Scotland*

**33.105** Professor Ludlam said that, by the spring of 1983:

[I]t was becoming clearer that there was [sic] some strange things happening to the immune system of people with haemophilia. A number of reports in the medical press of immune abnormalities in patients with haemophilia who were otherwise feeling well. It was – the interpretation that you could put upon those that was puzzling us. I would say that similar abnormalities were shown in gay men who were otherwise feeling well. And the question is in fact: were all these ... individuals in the United States already infected with a latent, if you like, AIDS virus?<sup>160</sup>

**33.106** The background is set out in Chapter 9, *Knowledge of the Geographical Spread and Prevalence of HIV/AIDS 1*, and Chapter 11, *HIV/AIDS Aetiology*. Until 1983 there had been very few reports of AIDS in haemophilia patients. Most reports of AIDS related to homosexual men and drug users. In patients with clinical AIDS, immune tests revealed a severe deficiency of T-helper (CD4) and an increase in T-suppressor (CD8) lymphocytes, together with disturbance in the normal ratio of CD4:CD8 cells. Many homosexual men who had no symptoms suggestive of AIDS were also found to have similar immune abnormalities although in milder form.<sup>161</sup> A letter highlighting immune abnormalities in haemophilia patients in the USA was published in *The Lancet* on 30 April 1983.<sup>162</sup>

**33.107** These findings led to studies being undertaken in the USA to assess the immune status of apparently well, asymptomatic haemophilia patients. The initial studies demonstrated that many asymptomatic haemophilia patients had immune abnormalities similar to those found in asymptomatic homosexuals. The cause of the immune abnormalities was unclear and it was uncertain whether they were progressive. As with homosexual men, there were, at the outset, a number of possible explanations apart from an 'AIDS virus' for the abnormal immune test results found in haemophilia patients. In his statement, Professor Ludlam explained that the cause of the immune changes might have been related to the widespread prevalence of an 'AIDS virus' or due to some side effect of Factor VIII treatment or it might even have been a previously unreported feature of the condition of haemophilia.<sup>163</sup> For him, the finding in 1982–83 of immune abnormalities in asymptomatic haemophilia patients in the USA was 'perplexing and worrying'.<sup>164</sup>

**33.108** With the possibility that some US haemophilia patients had apparent immune dysfunction which might have been related to their treatment, might have been progressive and might lead to an AIDS state, Professor Ludlam sought the help of a colleague, Dr C. M. Steel, at the Medical Research Council Unit at the Western General Hospital in Edinburgh, to investigate the possibilities. They decided to monitor the immunological status of some

of Professor Ludlam's patients. This was called the 'AIDS study' and these words were written on forms used for requesting blood to indicate that the sample should be sent to Dr Steel for further analysis.<sup>165</sup>

### The 'AIDS study'

**33.109** Professor Ludlam approached Dr Steel around January or February 1983. He thought it took a few weeks to negotiate what they wanted to do and that the first blood samples were probably sent to Dr Steel's laboratory around March 1983.<sup>166</sup> The earliest available evidence known to the Inquiry of blood being taken for the 'AIDS study' is a haematology form so annotated and dated 14 March 1983.<sup>167</sup>

**33.110** In his laboratory, Dr Steel established a facility using specific antibodies to measure by microscopy the proportion of CD4 and CD8 lymphocytes in patients' blood. When patients attended the haemophilia clinic for review or for treatment, blood taken for routine investigations would be sent to the Haematology Laboratory in the Royal Infirmary of Edinburgh (RIE) as normal. There the full blood count would be assessed in the usual way by the haematologists except that instead of counting 100 white cells under the microscope to quantify the different types of white cells, as was usual, 200 cells were counted to obtain a more accurate estimate of the number of lymphocytes. Lymphocytes only constitute a relatively small proportion, approximately 15–25%, of the total number of white cells. Counting a larger number of total white cells made it more likely that a 'precise estimate' of the number of the lymphocytes was obtained before proceeding to divide the number of cells further into CD4 and CD8 lymphocytes.<sup>168</sup>

**33.111** No extra blood was taken for the lymphocyte studies. The same sample was processed and analysed by the RIE Haematology Laboratory and by the Western General Hospital, Edinburgh.<sup>169</sup> Once the Haematology Laboratory had counted the 200 cells, the same blood samples were then couriered to Dr Steel's laboratory, where the proportions of CD4 and CD8 lymphocytes were assessed. By this means it was possible to measure the proportion of each type of lymphocyte in the blood, as well as their absolute number.<sup>170</sup>

**33.112** Professor Ludlam said that he did not specifically select particular individuals for study. The patients studied were attending the clinic for review or for treatment of an acute bleed and needed to have blood taken for their routine monitoring. He said that all the patients would have been seen by either himself or one of his Registrars. It had been agreed between Professor Ludlam and his Registrars that if blood was being taken from patients it would be assessed for lymphocytes. That would have arisen out of discussion, probably initiated by Professor Ludlam.<sup>171</sup>

<sup>171</sup> Professor Ludlam – Day 39, page 30; Note of a meeting between Professor Ludlam and the Penrose Inquiry legal team [PEN.012.0774] at 0779

**33.113** There may well have been patients who attended the clinic but did not have blood taken for the 'AIDS study'. Samples were taken from patients with severe and moderate haemophilia because they were the patients who had received large quantities of factor concentrates. Professor Ludlam said that if a patient with mild haemophilia attended the clinic they might not have sent a sample of their blood to Dr Steel because the patient might not have had any blood product treatment at all in their life. Even amongst patients with severe and moderate haemophilia, Professor Ludlam said that he might not have needed to take blood from them for other routine reasons and, in that case, he would not have taken blood just to do these tests. It also probably depended to some extent on the time of day a patient was seen. Because the samples had to be ferried across from the RIE to the Western General and processed the same day, if a patient came in late in the afternoon the technicians may not have put that sample through for the lymphocyte assessment due to time constraints.<sup>172</sup>

**33.114** Professor Ludlam estimated that 50–70% of his patients had samples taken from them for the purposes of the 'AIDS study' over the 'next little while'.<sup>173</sup> Data published in the follow-up article in *The Lancet* on 30 June 1984 were derived from samples from a smaller cohort, 47 individuals, around 25–30% of his patients.<sup>174</sup>

#### Characterisation of the 'AIDS study'

**33.115** Professor Ludlam told the Inquiry that he did not obtain ethical approval for the 'AIDS study' because he considered it to be an extension of routine monitoring of his patients and not medical research. He considered that the lymphocyte studies became part of the general monitoring of patients for potential adverse effects of therapy in 1983: if the CD4 and CD8 cells could have been distinguished visually in the routine haematology laboratory procedures, there would have been no need to send them to Dr Steel.<sup>175</sup> He said:

We viewed this endeavour as part of our obligation to monitor people with haemophilia .... [I]t was my responsibility to monitor patients for side effects of therapy ....

And as immune abnormalities had been demonstrated in apparently well haemophiliacs in the United States, it seemed appropriate that I should assess our patients here in Edinburgh, to see whether they had any immune abnormalities. This was something completely new and important as part of the monitoring process.<sup>176</sup>

**33.116** This led to discussion of the proper characterisation of the study, in light of accepted ethical rules at the time. Professor Ludlam distinguished the 'AIDS study' described above from a later extension of his study of the immune functions of his patients in 1984 – the 'skin test' series of investigations. It is important to compare and contrast his approach to the two studies in considering the position he adopted.

<sup>176</sup> Professor Ludlam – Day 35, pages 44–45

## Skin tests

**33.117** The skin tests were carried out after the lymphocyte studies and provided another immune function measurement. Professor Ludlam said that he wanted to look at the patients in a 'rather more holistic way' and that the skin tests assessed many more aspects of the functioning of the immune system than counting the CD4 and CD8 cells.<sup>177</sup>

**33.118** Professor Ludlam sought and obtained ethical approval for the new test by writing to the RIE Ethics Committee and explaining what he wanted to do. In particular, he sought approval to ask patients with haemophilia and about 15 or 20 controls if he could use a commercially available 'Merieux multitest' device on their forearm to measure their immune system to try and better define the apparent immune deficiency that had been shown up by the CD4 and CD8 counts.<sup>178</sup> Professor Ludlam's letter dated 3 May 1984 seeking approval is not available but the skin tests were approved by the Ethics Committee by letter dated 24 May 1984.<sup>179</sup> The letter, from Dr de Bono, is entitled, 'Skin tests in patients with congenital bleeding disorders'. It states that Dr de Bono considered that it would be 'perfectly in order to proceed with the tests outlined in your letter'.

**33.119** The 'multitest' device was a much more holistic way of testing the immune system than measuring the CD4 and CD8 counts. Professor Ludlam thought that 20 or 30 patients were tested in this way. Although some of the patients may have been asked to attend the clinic for this purpose, he thought that it was likely to have been more opportunistic: he probably asked patients who were attending the clinic for review, for treatment or to collect home treatment if they would mind volunteering.<sup>180</sup>

**33.120** Professor Ludlam told the Inquiry that patient consent was obtained before the skin tests were done.<sup>181</sup> He did not think that the patients' consent was recorded in their notes, however, and there was no record of any written consent for blood tests obtained at that time.<sup>182</sup> He said that he obtained verbal consent which is what he had been asked to do by the ethics committee.<sup>183</sup>

**33.121** Professor Ludlam said that he explained to patients what the skin tests involved. It was slightly invasive and it inconvenienced the participants because they had to come back to the clinic two days later.<sup>184</sup> He said that he would have told patients that he was testing their skin because the reactions that he could measure reflected the way in which the immune system was working. He was certain that he would have told the patients that this was part of a study into the lowering of the immune system of haemophilia patients in Edinburgh.<sup>185</sup>

**33.122** When asked what the difference between carrying out the skin tests and carrying out the investigation of CD4/CD8 counts was from a consent point of view, Professor Ludlam said:

<sup>184</sup> Professor Ludlam – Day 35, pages 67–68

<sup>185</sup> Professor Ludlam – Day 39, pages 36–37

[T]he skin tests, involved something being done to the patient. It was invasive ... and it wasn't quite as clear what we might gain out of this. So it was a much more speculative investigation compared with the CD4/CD8 counts.<sup>186</sup>

**33.123** Whether or not the line drawn between steps taken in 'monitoring patients' on the one hand and research on the other was correctly drawn, or was indeed fully rationalised at the time, is not clear. What is clear is that when his studies of the immune functions of his patients crossed what he perceived to be the line between routine management and research he sought ethical approval for what he proposed to do.

**33.124** Some witnesses who were part of the AIDS study only found out that they were part of it when they recovered their medical records at a later date. From their perspective, a study was carried out on their blood samples and details of the study subsequently published in *The Lancet* without their consent or knowledge. Professor Ludlam said that he believed that he had implied consent to 'monitor' his patients by testing their blood for immunological abnormalities as part of general monitoring. Patients were used to blood tests being taken for various purposes. He did not require fresh blood samples for the study.<sup>187</sup>

**33.125** He told the Inquiry that he was sure that he would have explained to those people who were part of the immune studies, commenced in 1983, that there was a very new condition called AIDS about which very little was known and that there was a possibility that it might be spread by blood products. He thought that he would have tempered that by saying that the risk to patients in Edinburgh was minimal as they had received only Factor VIII prepared from plasma collected from donors in Scotland and at that time there were no cases of AIDS in Scotland.<sup>188</sup>

**33.126** It would have been understandable if his position in evidence had been that the study was no more than a preliminary investigation, that he did not set out systematically to inform patients about the study, that some may have got information about the study by asking questions or casually from observing documents but that he could not express any view as to the proportion of those in the study who knew about it. Unfortunately, the evidence became rather confused as Professor Ludlam sought to explain how patients would or might have become aware that the study was being carried out. The problem began with notations on the haematology request forms.

### Haematology request forms

**33.127** Professor Ludlam explained that there was a routine haematology request form in use at the RIE. The form started off beside the patient and went with the patient's blood sample to the laboratory. Normally the form did not go to Dr Steel but was returned to the haemophilia centre once routine haematology had been completed.<sup>189</sup> The haematology forms accompanying samples destined for Dr Steel had the words 'AIDS study' written on them.<sup>190</sup> That informed the haematology laboratory of the need to count 200 cells and send the sample on to Dr Steel. Professor Ludlam was referred to one of the forms and he explained how the form was filled out and what the various data recorded on it represented.<sup>191</sup>

<sup>190</sup> Extract from medical records [WIT.004.0800]

<sup>191</sup> Professor Ludlam – Day 35, page 42

**33.128** The labelling of the samples as ‘AIDS study’, intended as a form of shorthand to identify them for processing in Dr Steel’s laboratory, was, as Professor Ludlam put it, ‘unfortunate’.<sup>192</sup> This was later to give rise to suspicion on the part of some patients that he was carrying out experiments on his patients. In the view of this Inquiry, that suspicion is entirely without foundation. In oral evidence, Professor Ludlam said:

We weren’t studying AIDS, we were assessing CD4 and CD8 lymphocytes, but we were doing that because of the reports of immune abnormalities in people with haemophilia from the United States, who were well but had abnormal lymphocyte counts ....

And a few patients with haemophilia in the US developed AIDS .... The overall topic, the umbrella topic was ... AIDS ....

Subsequently it emerged much later on, when one or two patients asked for... copies of their case notes and they saw these report forms in the case notes, they wondered whether, I think, we had undertaken some sort of AIDS – some sort of different AIDS study, whether we had given people AIDS, whether we had given patients concentrates, clotting factor concentrate, that we knew was infected with an AIDS virus. One story that came to me was that we had put HTLV-III into bottles of clotting factor concentrate, heat-treated them and then given it to the patients to see whether the heat treatment was effective.<sup>193</sup>

**33.129** The emergence of these suspicions appears to be an important link in the chain of events which has led to this Inquiry. This is a matter to which the Inquiry will return.

**33.130** These anecdotes emerged after the event and cast doubt on the extent to which patients knew of the study at the time it was carried out. However, as the evidence emerged, it became clear that the form was the first possible intimation to patients that they were involved in the ‘AIDS study’. Professor Ludlam explained:

[T]o make sure that they were correctly carried out in the laboratory, I labelled the blood forms “AIDS Study”. These would be forms that would be handed to patients to get their blood taken and, you know, patients could read it. So I must have explained something about AIDS because I wouldn’t write “AIDS Study” on a form, which I then either handed to the patient or was sitting in front of the patient while they were having their blood taken, without some explanation.<sup>194</sup>

**33.131** When patients attended the review clinic at the Medical Out-patient Department there would be an opportunity to discuss what investigations were being carried out as the doctor was talking to the patient. Professor Ludlam thought that the doctors would have explained to their patients why the immune studies were being done at the point of completing the form. He thought that they would have said that there had been reports from North America of a few haemophilia patients developing AIDS and they were keen to do some tests to assess the immune function of patients at the Edinburgh Haemophilia Centre, who they did not think had been affected by whatever the AIDS agent was.<sup>195</sup> Professor Ludlam told the Inquiry that the staff at the Haemophilia Centre were keen for

---

<sup>192</sup> Note of a meeting between Professor Ludlam and the Penrose Inquiry legal team [PEN.012.0774] at 0778

<sup>193</sup> Professor Ludlam – Day 35, Pages 49–50

<sup>194</sup> Ibid page 19

<sup>195</sup> Professor Ludlam – Day 36, page 7

patients to know about the immune function studies and that doctors had 'no inhibitions' about writing 'AIDS study' on the request forms which were then given to patients.<sup>196</sup>

**33.132** The patient would take the form (possibly along with one or two other routine monitoring forms) into another room and give it to a nurse who would take the blood sample. Professor Ludlam noted that until that time it had generally been deemed to be a doctor's responsibility to take blood and that the RIE haemophilia clinic was one of the first in which nurses were able to take blood.<sup>197</sup> Sometimes the patient would have to sit in a queue with other patients and wait for the nurse with the form in their hands.<sup>198</sup> After drawing the sample, the nurse would put the tube containing the blood sample into a polythene bag along with the request form and put it out for a porter to collect and take to the laboratory.<sup>199</sup> Professor Ludlam thought that at that time the polythene bags had two compartments to them, with the blood sample put into one compartment and the request form put into the other before the bag was then sealed. Professor Ludlam was certain that the request form was not wrapped around the sample in case the sample leaked and the tube and form were covered in blood.<sup>200</sup> Professor Ludlam stated that patients will generally examine forms if they are given to them: 'if you give them forms, they read them'.<sup>201</sup>

**33.133** He said that his Registrars and the nurses in the centre worked as a team and had agreed the approach described. He therefore thought that it was very likely that the nurse taking the blood would have told the patient about the study, although he did not think that he would have formally instructed them to do so. He accepted that it was an 'informal', although not 'casual', arrangement.<sup>202</sup>

**33.134** Samples were also taken from in-patients, such as those admitted for the treatment of an acute bleeding episode. In such cases, on occasion the forms would have been completed the previous day because the ward doctor would have a lot of patients to go round and take blood from: it was quicker if the forms were all made out in advance.<sup>203</sup> The form would be taken to the patient's bedside and the sample taken and put in the polythene bag and sent off to the laboratory in the manner described above. The completed request form would often be put down next to the patient who would be able to read the request form while the blood was being taken.<sup>204</sup>

**33.135** If a patient had not been seen for a while or if there was something unusual about their clinical state, blood samples would be taken to investigate their condition. All samples would be taken when the patient was treated: the centre staff did not take blood for investigation and then puncture patients again later for treatment.<sup>205</sup>

**33.136** Professor Ludlam could not recall any written protocol for taking blood samples within the Haemophilia Centre or the hospital generally. He thought 'custom and practice' dictated procedures.<sup>206</sup>

<sup>205</sup> Ibid page 7

<sup>206</sup> Professor Ludlam – Day 36, page 5

**33.137** Professor Ludlam referred to a letter from Dr John Tucker, Consultant Haematologist at the Borders General Hospital, dated 11 January 2006, which explained the process of taking blood from patients. The letter states:

When patients were inpatients the medical staff completed the request forms and obtained verbal consent which included explaining the need for the samples. They would then draw the sample. This was my practice and I would expect that my colleagues behaved in the same way. Certainly no additional samples would be taken if the patient were to express any reservation or objection. In 1984 we were monitoring immune function of haemophilia patients and used the shorthand notation of 'AIDS study' when taking surveillance specimens. Again patients were aware of this practice when taking immune surveillance samples.<sup>207</sup>

**33.138** In her statement, Sister Billie Reynolds, who worked in the Edinburgh Haemophilia Centre from 1988, said that blood was usually taken first and then the label for the sample would be completed. She also said that she would be asked for samples by Professor Ludlam's Registrar. She would be told simply to tell the patient that the sample was 'for research'. Some patients would consent readily, while others would ask what the research was. If she did not know, she would refer the patient to the doctor who had requested the sample.<sup>208</sup>

**33.139** As the narrative of this evidence indicates, it would have been altogether simpler to have told patients directly and explicitly that studies in the USA had suggested that concentrate therapy might be associated with changes in patients' immune systems, that it was important to find out whether similar changes were happening in patients treated with SNBTS products and, if they were, to consider how best to deal with the situation. Professor Ludlam suggested that, up to a point, an approach along these lines had been taken.

**33.140** Professor Ludlam said that he was not trying to keep the immune tests secret. He said that patients knew that he had an interest in monitoring the safety of clotting factor concentrates. He thought that the patients were aware that the immune function tests were being carried out.<sup>209</sup> When asked whether the patients knew whether they were involved in the 'AIDS study' at the time, however, Professor Ludlam said that he was not sure if they all knew:

I can't assure you that every patient understood exactly what was done but we were making it clear that we were doing this.<sup>210</sup>

**33.141** He said that it was possible that not all patients were told about the 'AIDS study' but he considered that at least some were told, although he was unable to estimate how many patients that might have been.<sup>211</sup>

<sup>209</sup> Professor Ludlam – Day 35, page 57

<sup>210</sup> Ibid page 55

<sup>211</sup> Ibid page 57

**33.142** However, he also said that he was not surprised that some patients did not understand that they were being involved in an AIDS study:

I think it's not always possible to convey ... information ... to people. They may have forgotten they had been told. We may not have told them. This was part of the monitoring of patients that was my responsibility ... if we had asked them exactly what was happening to the full blood counts that we had been doing for years they might be a bit vague and the same for the chemistry tests, and this was just another test that was important – it was something ... new, but it was my responsibility to do this and to see what the results were.<sup>212</sup>

### Findings of the immune function studies

**33.143** Professor Ludlam said that it was observed from the initial studies in 1983, to great surprise, that the pattern of lymphocyte abnormalities in Edinburgh patients was similar to those observed in the USA; yet none of the individuals had any symptoms or signs suggestive of AIDS. As the majority of patients had only received blood components or products prepared from Scottish blood donors, and there were at that time no AIDS cases in Scotland, it seemed rather unlikely to Professor Ludlam that the lymphocyte changes were due to a possible ubiquitous AIDS virus. The cause of the immune changes in the Edinburgh patients was unknown but there were a number of possible explanations related to the underlying condition of haemophilia and its treatment. It was thought to be imperative to monitor the patients because, if the immune changes were becoming progressively more abnormal, there might be a risk of their developing opportunistic infections (such as *Pneumocystiscarinii* pneumonia or Kaposi's sarcoma) which were characteristic of AIDS.<sup>213</sup>

**33.144** Patients were only advised of the results of the lymphocyte studies if they asked.<sup>214</sup> Professor Ludlam accepted that, since at least some of the patients were not aware that they were being studied, those patients could not have asked for their results.<sup>215</sup> He said that he did not take any steps to advise patients of the results because he did not know how to interpret them. He was, he explained, 'perplexed' by the findings of the study and was not sure what their clinical significance was. The clinicians had expected them to be normal. They were themselves uncertain as to what the results might mean and it did not seem helpful to go back and pass on the information to the patients.<sup>216</sup>

**33.145** Professor Ludlam said that he was also a little hesitant because the technology that they were using was not what would be used today:

It doesn't have the high degree of sophistication for counting numbers of cells ... we counted cells manually. It's a very imprecise way, particularly when there are small numbers of lymphocytes.

So the results didn't seem to have the same degree of precision as I would have liked and I think these were not standard laboratory tests for which there were well defined normal ranges ....

This was not, and couldn't be at that stage, well quality controlled.<sup>217</sup>

<sup>217</sup> Professor Ludlam – Day 39, pages 14–15

**33.146** The results of the lymphocyte tests carried out were initially recorded on paper records.<sup>218</sup> Professor Ludlam explained:

It was much later in fact, when we were moving hospitals, that we were tidying up and came across a box of these and one of my staff said, 'Well, what do we do with these?' I was told all the information was in the computer so should we not just throw them out? And I thought, 'Well, it's part of the clinical record, we should put it back in [the] case notes ....' so they were added very much later, about 2003.<sup>219</sup>

**33.147** He explained that they were not part of individual patients' case notes from the beginning because they had the information on computer along with a lot of other information. The forms had to be kept while they were waiting for the results to come back from the Western General and they did not all come back at the same time so they accumulated in a box. Professor Ludlam explained that when AIDS 'became more of an anxiety' there emerged a desire not to put such information in patients' case notes.<sup>220</sup>

**33.148** Three aspects of this evidence cause particular difficulty in classifying the immune studies as 'monitoring' of patients' immune systems. Firstly, the request forms referred to the exercise as a 'study'. The exercise was limited in scope, and did not involve structured follow-up or sequential studies of the patients. Secondly, the suggestion that comparison with contemporary technology made Professor Ludlam 'hesitant' about the investigation is irrelevant to the perception at the time: later technological developments could not have been anticipated in any but the most general of terms. Publication on the assumption that later technology might undermine the conclusions of the study is an unlikely occurrence. Thirdly, and perhaps most significantly, omitting the forms and results from patients' case notes inevitably meant that the information was not available to clinicians and others consulting the notes unless they had been involved in the study and knew of the existence of an independent record. Thus far, the evidence tends to support the notion that the 'AIDS study' was research.

#### Publications in *The Lancet*, May 1983 and June 1984

**33.149** Professor Ludlam told the Inquiry that, as he had data showing abnormalities in his patients with haemophilia, who had been treated with blood products collected in a non-AIDS country but which were similar to those highlighted in US patients in the letter in *The Lancet* on 30 April 1983,<sup>221</sup> it seemed important to submit the data for publication. He considered that the report would offer alternative explanations, other than widespread infection by a putative virus causing AIDS, for the immune abnormalities observed in US haemophilia patients.<sup>222</sup>

**33.150** A preliminary report of Professor Ludlam's findings was published in *The Lancet* on 28 May 1983.<sup>223</sup> The study related to samples from 23 patients with severe haemophilia and von Willebrand's disease who had only received SNBTS Factor VIII, Factor IX or cryoprecipitate in the past five years. All were clinically well.

<sup>222</sup> Professor Ludlam's note on long term safety monitoring for transfusion-transmitted infections [PEN.012.0351] at 0353

<sup>223</sup> Ludlam et al, 'Disordered immune regulation in haemophiliacs not exposed to commercial Factor VIII', *The Lancet*, 28 May 1983 [LIT.001.0416]

**33.151** This preliminary report was followed up by a more detailed description of the observations in a further article in *The Lancet* on 30 June 1984.<sup>224</sup> By this stage samples from 47 patients (including the 23 patients sampled previously) had been taken.<sup>225</sup>

**33.152** It is clear from the reports of these studies that as late as June 1984, Professor Ludlam had formed, and continued to hold, the view that something other than a putative AIDS virus, associated with possible 'antigen overload', was causing immune abnormalities in some at least of his patients, similar to but less severe than those associated with AIDS. He did not discuss the antigen overload theory with his patients because it was not clear what should be done if that was the cause of the apparent immune dysfunction.<sup>226</sup>

**33.153** Later, by analysing stored samples retrospectively, it was shown that at the time the samples had been analysed the patients were all negative for anti-HTLV-III. The changes in distribution of lymphocyte cells that were observed and reported in the published article were not associated with viral infection. However, retrospective examination also showed that, by the time the paper was published on 30 June 1984, some of the patients included in the study had become infected with HTLV-III in the interval.<sup>227</sup>

**33.154** Professor Ludlam said that reporting the results of his monitoring of the patients was not limited to the 1983–84 publications describing lymphocyte abnormalities:

[T]his stretched on into ... the [Edinburgh] cohort.<sup>228</sup> It was new information that came out of examining the immune systems of these patients. So it was new information. In that sense it was research but I would call it "new information" – if I had not published it, it would have been monitoring. I don't see that it necessarily becomes research because I have published it. In a sense it's what we might call these days an "audit".<sup>229</sup>

**33.155** This answer added to the difficulty of accepting that the study was properly characterised as 'monitoring' of the patients. New information is, perhaps invariably, what one hopes to derive from research. Until it is published, it remains unpublished research. It is difficult to understand how a decision to withhold new information from publication of itself transforms it into monitoring of patients. It is less difficult to envisage a situation in which new information derived from research becomes relevant to monitoring as part of the follow-up of the patient: it might be hoped that would be normal. That would not, however, change the character of the exercise from which the new information was derived.

### *Immunological studies: the Glasgow Royal Infirmary*

**33.156** Immunological studies were also carried out in Glasgow. In contrast to practice in Edinburgh, Glasgow patients were exposed to a mixture of blood products, including imported concentrates. In this respect the context for the study was different.

<sup>229</sup> Professor Ludlam – Day 35, pages 63–64

**33.157** Like Professor Ludlam, Professor Forbes said that early in 1983 a variety of investigations had shown evidence that haemophilia patients who had received multiple transfusions of Factor VIII and Factor IX concentrates had immunological abnormalities. Professor Forbes and his colleagues therefore undertook to look at their own patients to see if any abnormalities were occurring in them as a result of concentrate infusion.<sup>230</sup> The minute of the meeting of the haemophilia and blood transfusion working group at St Andrew's House on 22 March 1983 already mentioned, indicates that Dr Forbes (as he then was) was conducting a study of the immunological status of haemophilia patients at that time.<sup>231</sup>

**33.158** He and his colleagues were able to show that there was indeed suppression of immunological function in their patients. Again in common with Professor Ludlam, it was not clear to Professor Forbes at the time that the suppression was necessarily due to the transfusion of blood products over a period of time. Although that was certainly felt to be a possibility there was some doubt. He explained that there might have been something else happening at the time to cause immune suppression, apart from a ubiquitous AIDS-causing virus, that they did not know about. He and his colleagues were cautious about drawing their conclusions.<sup>232</sup>

**33.159** In Glasgow, blood samples were taken specifically for the immunological study. The patients all knew about the study because they volunteered to give blood and all of the tests were carried out on fresh blood samples, although the patients were not informed in great detail of the implications of the study. It was not clear to Professor Forbes himself what the implications might be.<sup>233</sup> He said that patients were asked if they would mind giving a sample of blood, that they were going to look at some immunological tests and required fresh blood samples to look at their cells and see if there was anything happening that they should know about. Professor Forbes said that it was probably mostly himself who asked the patients for samples, although Dr Madhok and Professor Lowe may also have asked.<sup>234</sup>

**33.160** Dr Froebel, who had participated in the running of the study, could not remember the exact date it had commenced, although she thought it was in 1982 when she moved into the new Department of Medicine research laboratory at the GRI.<sup>235</sup> She was a post-doctoral research fellow at the time, working on the cellular immunology of rheumatoid arthritis. Soon after the move, Professor Forbes approached her about a new syndrome of immune deficiency that appeared to be affecting, among others, patients with haemophilia in California. She responded by saying that apart from one assay (the 'natural killer assay') which she thought that she would be able to develop, she was already able to apply all of the other tests that were used on the Californian patients. She suggested testing samples from 10 patients to see if there were any similarities. In the end she carried out numerical immunological tests, for proportions of lymphocyte sub-populations, and functional tests, looking at T cells and natural killer cells, for their response to mitogens and their natural killer activity, on samples from 19 patients.<sup>236</sup>

<sup>234</sup> Day 33, pages 109–111

<sup>235</sup> Dr Froebel's statement on immunological testing in Glasgow [PEN.012.1628]

<sup>236</sup> Dr Froebel's statement on immunological testing in Glasgow [PEN.012.1628]. Dr Froebel's statement refers to testing 17 patients, whereas the published paper discussed below refers to 19 patients, 17 with Haemophilia A and two with Haemophilia B.

**33.161** After the study was completed the results and implications of the results were not communicated to the patients. Professor Forbes said that he was not sure if he knew that there were implications or, if there were, what they meant:

I don't think we understood what was really happening. We were able to show that using these particular tests, no matter how primitive they were, there was something happening and it seemed to be associated with the amount of material given to them.

Whether it was a direct effect of some component of the blood products given, we weren't clear. So this was very much a preliminary paper, suggesting that there were immunological abnormalities. What they meant, I don't think at that time we knew, and I'm not sure that we even know at this time.<sup>237</sup>

### Publication

**33.162** An article by Dr Froebel and others entitled, 'Immunological abnormalities in haemophilia: are they caused by American Factor VIII concentrate?' was published in the *BMJ* on 15 October 1983.<sup>238</sup> The article reported the study of cellular immunity in the group of 19 haemophilia patients at the GRI referred to above. These 19 patients were all treated at the Haemophilia Centre at the GRI and all had received different treatments over the preceding years.

**33.163** Table 1 of Dr Froebel's paper showed a significant difference between the patients and the controls. She had presented it a meeting of the Scottish Medical Society, she thought, in the spring of 1983 and it was published soon after as an extended abstract in the *Scottish Medical Journal (SMJ)*. She thought the *SMJ* paper was the first report in the UK of what was later understood to be HIV/AIDS.<sup>239</sup>

### Consent to publication

**33.164** Professor Ludlam told the Inquiry that patient consent to publish was not obtained for his papers. He did not think that it would be necessary because the results were anonymised.<sup>240</sup> It never occurred to him to get the patients' consent because that was not usual practice when patients were not identifiable from the information published and there was no information in the two publications that would allow the identification of any individual patient: it was group data. He thought that it would have been unusual at that time to go back to the patients and say 'these are the results, we would like your permission to publish them'. If he was going to publish a case report on an individual who might be identifiable then he would have discussed his intentions with the patient, explained why it was interesting and asked for permission. He thought that he would have done that for a (specific) 'case report' at the time, although it was not then an ethical requirement.<sup>241</sup>

**33.165** As already noted, Professor Forbes did not go back to his patients with the results of the Glasgow study.

***Skin test: the Glasgow Royal Infirmary***

**33.166** It appears that the Glasgow skin test exercise was carried out later. It was referred to in a letter to patients circulated on 8 January 1985 as a test Professor Forbes and Professor Lowe *wanted* to carry out, indicating that it still lay in the future at that time.<sup>242</sup> Whether ethical consent was sought is not known but patients were at least informed of the wish to test.

**Testing for anti-HTLV-III*****The UK context***

**33.167** Between 1982, when treating doctors first became aware of AIDS in the USA, and 1984, when the first tests became available, there was a lot of uncertainty about all aspects of the condition. By the end of 1983 most haemophilia clinicians would have accepted the view that the condition was caused by a blood-borne infectious agent which was transmissible by blood products. Commercially produced factor concentrates were thought by many to be more likely to transmit infections than concentrates made from local (UK) blood. However, the medical consequences of infection were unclear. The 'antigen overload' theory, that immune deficiencies in recipients of factor concentrates occurred without an infective agent of transmission, persisted (and was ultimately shown to be valid, at least to some extent in some cases).

**33.168** The number of diagnosed cases of AIDS among persons with haemophilia was relatively low in 1983: possibly only two in the UK. The CDC definition of 'AIDS' had been adopted for reporting purposes. The CDC criteria stressed the importance of the diagnosis of opportunistic infection. A definitive diagnosis would be attached if the patient developed intractable disease.<sup>243</sup> By November 1984, 21 cases of AIDS or AIDS-related illness (none in Scotland) had been reported to Dr John Craske of the Public Health Laboratory Service (PHLS).

**33.169** Emphasis on this diagnostic test necessarily underestimated the prevalence of HIV infection in the haemophilia population, given the potentially long period before evidence of opportunistic infection might appear in individual patients. The focus changed in 1984 when testing for antibodies to HTLV-III had become a reality.

**33.170** By July 1984, Professor Richard Tedder at the Department of Virology at the Middlesex Hospital, along with Professor Robin Weiss of the Chester Beatty Laboratories and a group of colleagues, had developed an early competitive radioimmunoassay test for the detection of antibodies to the putative virus causing AIDS. The test was still under development at that time and was considered to be a 'research assay', but it was used to carry out an extensive programme of research.<sup>244</sup> The result was the article by Cheingsong-Popov and others already mentioned which was published in *The Lancet* on 1 September 1984. Two thousand people in the UK had been tested for antibody to HTLV-III.<sup>245</sup>

**33.171** Blood samples had been made available by healthcare professionals in a number of clinical areas: GUM physicians, haematologists looking after haemophilia patients and people providing care to intravenous drug users. Following this publication, clinicians

<sup>245</sup> Cheingsong-Popov et al, 'Prevalence of antibody to human T-Lymphotropic virus Type III in AIDS and AIDS-risk patients in Britain', *The Lancet*, 1 September 1984 [LIT.001.0417]

caring for each of these risk groups contacted Professor Tedder asking him to test their patients, to delineate the size of the problem in their respective patient groups.<sup>246</sup> Samples were submitted for examination from around the UK. Professor Tedder told the Inquiry that the period following the publication of the data in the September paper 'was an incredibly difficult and busy time'.<sup>247</sup>

**33.172** Professor Tedder had the only laboratory in the UK which could carry out HTLV-III antibody tests at that time without access to US technology and know-how. By the end of 1984, Dr Philip Mortimer at the PHLS was also carrying out the tests developed by Professor Tedder.

**33.173** On 10 December 1984, the UKHCDO held a meeting to discuss recent developments in HTLV-III testing, although it is clear that, as in Glasgow and Edinburgh, some regional Haemophilia Centre Directors had information about the availability of tests before this meeting. The minutes show that it was known that Professor Tedder had a test available but that any expanded test programme would require large quantities of virus culture, which would depend on engaging third parties. Only the PHLS and Wellcome were interested in industrial scale production. After long discussion, it was agreed that each clinician would decide whether individual patients found to be antibody-positive should be informed but that, in general, information should be provided if asked for. Professor Tedder advised that information about the risks of sexual transmission should be provided.<sup>248</sup>

**33.174** On 14 December 1984, Professor Arthur Bloom (Chairman of the UKHCDO) sent a document entitled 'AIDS Advisory Document' to all Haemophilia Centre Directors, intended to express the position adopted at the meeting four days earlier.<sup>249</sup> The document recommended that haemophilia patients should be tested for HTLV-III antibody and that antibody-positive patients should be informed, reassured and counselled regarding transmission of infection, including the possible use of barrier contraception. It noted that tests for HTLV-III antibody were available for haemophilia patients via Professor Tedder and Dr Mortimer. The intent of the letter of 14 December, read in the light of the discussion, appears to have been that information, reassurance and advice should relate to transmission of infection. The discretion of the individual clinician, discussed at the meeting, was not dealt with in the document.

**33.175** Until mid-December 1984, there had been no 'universal' HTLV-III antibody testing of haemophilia patients in the UK. There had been no discussion among haemophilia directors. Nor was there any general agreement to test for HTLV-III antibody prior to this date. It appears that whether or not patients were tested prior to 14 December 1984 depended on whether the particular haemophilia director knew that Professor Tedder had a test available and had been in contact with his laboratory to arrange testing on an individual basis, or had contact with Dr Robert Gallo or Professor Luc Montagnier that provided for testing in their laboratories.<sup>250</sup> The larger haemophilia centres were actively concerned about the whole situation and had started to contact Professor Tedder to see if he could test their patients.

<sup>249</sup> UKHCDO AIDS Advisory Document dated 14 December 1984 [SGF.001.2388]

<sup>250</sup> The Institut Pasteur also produced a test for the isolate discovered by them. The Inquiry does not have evidence of its actual use in the United Kingdom.

**33.176** The patients at Dr Winter's centre (at Kent and Canterbury Hospital) were informed in late 1984 that a test had become available and that their blood was being sent to Professor Tedder for testing. Dr Winter noted that a number of other haemophilia centres saw the availability of the new test as merely an extension of their pre-existing screening programme and did not perceive any need to inform patients.<sup>251</sup>

**33.177** Dr Winter's clinic did not have stored samples and it was necessary for him to make appointments to take a fresh blood sample from his patients. He explained:

If you had to call for the patient to have blood taken, as I did, that was different because the patient would come in and say, "Why have you called for me?" So if you like, in other centres because they had had to summon the patients, inevitably they would be saying, "I know you were only here a month ago for your review but we have asked you to come back because we have now got access to this new blood test and this is what it's all about".<sup>252</sup>

**33.178** Dr Winter's evidence highlighted the differences between centres which sent stored blood samples and centres (like his own and the GRI) which had to take fresh blood samples from patients. He explained that centres with stored blood samples would have probably 'just gone off to the deep freeze and thawed them and sent them because they would have thought this is just yet another virus test'. It would not have occurred to them to tell the patients because (1) it wasn't their practice to tell patients about blood tests; and (2) they were not having to bleed the patients so they were not actually seeing the patients.<sup>253</sup>

**33.179** Dr Winter said that in 1984 there was no pre-test counselling. This concept emerged one or two years later as a result of the HIV epidemic and as the impact that a positive test had on a patient's life generally, including the possibility of not obtaining life insurance and mortgages, became clear.<sup>254</sup> He explained that it became apparent a few months after the AIDS test became available that, if a patient had this test performed, even if the result was negative, an insurance company or mortgage adviser might subsequently want to decline a proposal or increase the premium on the basis, presumably, of 'we think you might have been something of a risky individual to have wanted that test done in the first place'.<sup>255</sup> He said:

Never before in medical practice had there been a blood test where just by having it changed your prospects for things like insurance and mortgages. Whatever the result was. So for the first time in medicine, I think, it became necessary to talk to patients who had come in and say – these are all patients – remember, I'm an HIV physician. A patient would come in and say, "I split up with my boyfriend 6 months ago and I'm in a new relationship and I would like to have this test done". To reassure them you would say to them, "Before you do that, there are things we need to discuss. If you have this test done, even if it is negative, you might find it more difficult to get life insurance. If you have this test done, even if it is negative, you might find it more difficult to get a mortgage." So you talked the patients through really what the consequence

<sup>253</sup> Ibid, page 156

<sup>254</sup> Dr Winter's submission to the Archer Inquiry [PEN.015.0283] at 0287

<sup>255</sup> Dr Winter – Day 16, pages 157–158

was of a negative result and what the consequence was of a positive result. And that was a completely new concept, now standard; and that was what pre-test counselling became.<sup>256</sup>

**33.180** Dr Winter said this completely new concept evolved from mid-1985 onwards. He explained that pre-test counselling subsequently became standard practice. He emphasised that at that time (late 1984) there was no stigma about having a blood test done and there had never been any impetus for doctors to tell patients that they were carrying out certain blood tests. The fact of simply having a test had never previously affected the patient.<sup>257</sup>

### *Testing for HTLV-III: Edinburgh*

**33.181** Professor Ludlam knew Professor Tedder and, when he found out that an HTLV-III antibody test had been developed, he telephoned and asked Professor Tedder if he would test samples from some of the haemophilia patients at the Edinburgh Haemophilia Centre.<sup>258</sup> Professor Ludlam said that, at the time that he made contact, Professor Tedder was inundated with requests from various sources and had only a limited amount of reagent to carry out the tests. Following some discussion, agreement was reached to test 10 samples from Edinburgh.<sup>259</sup>

**33.182** Professor Ludlam's recollection was that he had contacted Professor Tedder in October 1984,<sup>260</sup> while Professor Tedder thought that he had tested the samples for Professor Ludlam sometime around August 1984. Unfortunately there are no paper records of this testing as Professor Tedder's laboratory was dismantled a few years ago and all papers from the early period of HIV were destroyed.<sup>261</sup>

**33.183** Whatever the precise date, the work carried out in Edinburgh in 1982–84 in pursuit of Professor Ludlam's immunological studies lost much of its significance, at least for the time being, when the first HTLV-III antibody test results became available. The belief among Scottish practitioners that the Scottish blood donor population was free from infection and that Scottish blood products prepared from Scottish plasma were therefore likely to be safe was undermined.

### **Selection of initial samples**

**33.184** The first group of samples sent to Professor Tedder were recent blood samples taken from storage in the deep freeze in the RIE Haematology Department. Blood samples routinely taken for virological testing were stored in the virology department and a parallel store was kept in the haematology department so that clotting assays could be carried out as part of the routine monitoring of haemophilia. Professor Ludlam thought that, at that time, the 'indefinite' storage of all blood samples was 'a very appropriate thing to do ... [and] seen as extremely good virological practice' and noted that this was done in many other centres throughout the UK.<sup>262</sup> No fresh blood samples were taken to send to Professor Tedder for testing for HTLV-III.<sup>263</sup>

<sup>263</sup> Professor Ludlam – Day 39, page 72; Note of a meeting between Professor Ludlam and the Penrose Inquiry legal team [PEN.012.0774] at 0782–83

**33.185** Consent was not obtained from patients prior to their blood samples being sent to Professor Tedder. Professor Ludlam thought it unlikely that at the time that the samples were taken patients would have been told that they might be used for anti-HTLV-III testing:

I don't think they would have been told because we had no idea when the testing would become available, that a viral aetiology would be forthcoming. And these were samples that were laid down ... periodically when patients attended.<sup>264</sup>

**33.186** Professor Ludlam said that he may have instructed one of his laboratory staff to look out 10 recent samples from the deep freeze in haematology, probably from patients with severe or moderate haemophilia who were frequent users of concentrate.<sup>265</sup> He could not recall whether he chose the names of the patients whose samples were sent to Professor Tedder himself or if he simply gave the instruction that 10 samples from patients with severe haemophilia were to be sent and left it to the laboratory staff to go through a list of patients and choose the samples.<sup>266</sup>

**33.187** On the first day of his evidence on this topic, Professor Ludlam told the Inquiry that he thought that he had specifically sent Professor Tedder 10 samples from patients who had only received SNBTS product.<sup>267</sup> Upon reflection, however, he acknowledged that his initial recollection was probably wrong. He later said that he thought that the 10 samples were probably from a mixture of patients who had received only SNBTS concentrates and patients who had also received commercial concentrates.<sup>268</sup>

**33.188** Professor Ludlam did not think that the immune function results from the earlier study informed his selection of the samples. He pointed out that, in retrospect, at that stage the CD4 and CD8 counts of those who were found to be anti-HTLV-III positive were the same as those who were anti-HTLV-III negative, and had not started to decline. He said that he was 'pretty certain' that the selection was made on the basis of concentrate history and not on participation in the prior immune tests. He said that there were no clinical signs of AIDS at that stage in any of the patients.<sup>269</sup>

#### Test results received 26 October 1984

**33.189** Professor Ludlam said that he received the test results from Professor Tedder in late October 1984.<sup>270</sup> He said that he remembered the conversation vividly and that Professor Tedder had telephoned him at home around 8pm.<sup>271</sup> Professor Ludlam then telephoned Dr McClelland at home, within five to 10 minutes of getting the results, to inform him of the fact that the SNBTS blood supply appeared to be infected.<sup>272</sup>

**33.190** Dr McClelland recorded the initial disclosure in a memorandum dated 20 November 1984 which he sent to Dr Perry and Professor Cash. The memorandum stated that Professor Ludlam had telephoned him at home on the evening of Friday 26 October 1984.<sup>273</sup>

<sup>273</sup> Memorandum from Dr McClelland to Drs Perry and Cash, 'Events Leading up to the Recall of Factor VIII Batch 023110090', dated 20 November 1984 [SNB.006.5996]

**33.191** Professor Ludlam's initial recollection was of being told that three patients had tested positive for HTLV-III antibody.<sup>274</sup> He was subsequently shown a copy of Dr McClelland's memorandum, which he did not recall having seen previously.<sup>275</sup> Paragraph one of the memorandum states:

On the evening of Friday 26/10/84 Dr Christopher Ludlam telephoned me at home to let me [Dr McClelland] know that six haemophiliac patients of his had developed antibody to HTLV3. He thought that three of these sero conversions could be attributable to the use of PFC products.<sup>276</sup>

**33.192** Professor Ludlam accepted that Dr McClelland's memorandum (which was written within a month of the phone call) was more likely to be accurate than his memory and that it was likely that six patients (not three) had been found to be HTLV-III antibody positive by 26 October 1984.<sup>277</sup> Professor Ludlam offered an explanation for his initial recollection:

The figure of three sticks in my mind because these were people who had all received SNBTS-only material and there may have been another three who had had commercial material and who were positive. And I would have made the quick assumption that maybe they got it from the commercial material. This would be before we had looked at the transfusion records. So that is a possible explanation. It was a long time ago – I just remember the – there were three that got one batch. That's what impressed me ....

And it may be that there were three others who had got commercial and because – as I say, I assumed that that they, in the first instance, without inspecting the transfusion records – assumed that they might have got it from the commercial [products].<sup>278</sup>

**33.193** The telephone call from Professor Ludlam to Dr McClelland on 26 October 1984 was the first indication to the transfusion service that the SNBTS blood supply had been infected. By 1 November 1984 a specific batch of Factor VIII concentrate, batch 023110090, was deemed the most likely source of infection and was recalled. Subsequent investigation of the source of infection is described in Chapter 10, *Knowledge of the Geographical Spread and Prevalence of HIV/AIDS 2*.

#### Further testing by Professor Tedder

**33.194** To investigate the situation further, Professor Tedder agreed to test additional samples from other patients<sup>279</sup> and Professor Ludlam arranged for further samples to be sent within a few days of receiving the initial results.<sup>280</sup> He could not recall how he selected which further samples were to be sent, although he thought that he might have selected samples from other patients who had received batch 023110090.<sup>281</sup> The results of the further tests were received on Friday 2 November 1984, when Professor Tedder reported

<sup>280</sup> Professor Ludlam – Day 35, page 103

<sup>281</sup> Professor Ludlam – Day 39, page 75

that a total of 16 patients in Edinburgh were apparently anti-HTLV-III positive.<sup>282</sup> Fifteen of these patients appeared to have been infected by a single batch. The number of patients infected by the implicated batch was later thought to be 18. These patients became known as the Edinburgh Cohort and are discussed further in Chapter 10, *Knowledge of the Geographical Spread and Prevalence of HIV/AIDS 2*.

**33.195** Professor Ludlam said that, in total, samples from between 50 and 70 patients were tested by Professor Tedder.<sup>283</sup> He thought it unlikely that they were all tested in one batch given that Professor Tedder had limited supplies of reagents and was receiving a lot of requests. He thought that they would have been tested 'over a month or two or three' but admitted that this was a guess.<sup>284</sup>

**33.196** All of the samples that were sent to Professor Tedder were labelled with the names of the patients from whom they had been taken.<sup>285</sup> Professor Ludlam said that this was the usual way of sending samples to the laboratory for testing because they were worried about transcription errors:

If identifying details about a patient, either their name or a number or an initial or a date [are used] – every time it is written there is a finite chance there will be a mistake .... [If] you have got a row of tubes in a rack and someone is writing numbers, for example, on them. It is very easy indeed to get numbers a bit confused, not to remember to up to the next number when you number the next tube. So if you write a name, it is rather more specific and is probably less likely to result in error.<sup>286</sup>

**33.197** The effect of Professor Ludlam's evidence was that the question whether testing should be anonymised did not raise ethical issues in late 1984 and that it did not do so in this context until the 1990s, partly in response to the HIV situation. He said that when the HTLV-III antibody tests became available it felt as if at last clinicians had some control of the situation and that it would be useful to know whether individual patients were negative or positive for anti-HTLV-III. Therefore the samples were sent as named samples.<sup>287</sup>

**33.198** When asked whether he had anticipated the problem which would be caused by obtaining positive test results for patients who had been tested without their consent, Professor Ludlam said:

I think it fair to say that we hadn't, or we certainly hadn't anticipated all the consequences of testing and why informed consent became so important. This was at a time when AIDS was – increasing numbers of people were developing AIDS and we were desperate to have a reliable marker and that's why it was useful to have them on a named basis. I entirely agree that, come 1985 ... the whole picture of testing changed and it became desirable to talk to patients in advance of testing.<sup>288</sup>

### *Testing for HTLV-III: the Glasgow Royal Infirmary*

**33.199** The history of the testing for HTLV-III antibody in Glasgow is confused. There is evidence that by the end of 1984 some patients from the GRI and Yorkhill Hospital had been tested for HTLV-III antibody. It is not clear who carried out the tests for Yorkhill hospital.<sup>289</sup> While the RIE sent samples to Professor Tedder at the Middlesex Hospital for testing, as described above, the GRI sent samples to Dr Gallo in the USA. How that came about, and whether there was a connection with Dr Gallo that facilitated the test, remains unclear.

**33.200** As he expressly admitted, Professor Forbes had difficulty recalling many of the events that had occurred nearly three decades ago. He informed the Inquiry that the initial testing of patients for the Glasgow Haemophilia Centre was carried out by Dr Mads Melbye at his laboratory in Denmark.<sup>290</sup> After he had given evidence, however, Dr Karin Froebel provided a written statement to the Inquiry indicating that the initial testing had in fact been performed by Dr Gallo in the USA.<sup>291</sup> The relevant paragraph for these purposes is:

Things were moving very quickly in the field. In the spring of 1984, two reports, from Montagnier in France, and Gallo in the US, claimed to have isolated a virus from patients with AIDS. Both were working on an antibody (ELISA) assay, a blood test that would show exposure to the virus. We were interested to know as soon as possible whether the Glasgow haemophiliac patients had antibody to the virus. In Glasgow there was a freezer-full of stored serum samples from an earlier study, which Dr Forbes suggested could be used. I wrote to both Montagnier and Gallo and had a reply from Dr Gallo directing me to send the samples to his research scientist. The samples (77) were located, I think by Dr Madhok, packed in dry ice, and Dr Forbes and I took them to Glasgow airport to be air-freighted to the laboratory in the US. At this point, I still thought the results would be negative; that we were dealing with something different in Scotland and I can still recall the shock when the news came back that 12 of our 77 samples, i.e. 16%, tested positive. Very soon after that, Mads Melbye appeared, and suggested writing a joint paper, pooling our results with his 22 Danish samples, and this resulted in the Lancet paper in December 1984.

At this point I recall Dr Forbes saying that he would speak to all the haemophiliac patients and tell them that they were at risk of infection, and should take the necessary safe sex precautions, ie use condoms. The test carried out in the US had not yet been approved by the regulatory body; therefore we could not say for sure that the 12 were definitely infected or that the 65 were definitely not. I also recall Dr Forbes telling me soon after, that he had spoken to all the patients. I had no direct contact with patients at any time.<sup>292</sup>

**33.201** Subsequently, in a letter to the Inquiry dated 27 June 2011, Professor Forbes advised that he was happy to defer to Dr Froebel's recollection of events on this matter and that what she described was a logical explanation of events although he did not actually remember sending samples to Dr Gallo.<sup>293</sup> As noted by Dr Froebel, the stored

<sup>292</sup> Ibid [PEN.012.1628] at 1629

<sup>293</sup> Immunological testing in Glasgow – Professor Forbes' comments on Dr Froebel's statement [PEN.012.1677] at 1678

samples were 'from an earlier study'. It is not possible to determine which study that was. The only near contemporaneous study about which the Inquiry has evidence is the immune abnormality study referred to at paragraph 33.159 above.

**33.202** Professor Forbes could not recall when he started collecting the samples. In the article mentioned by Dr Froebel, it is noted in the section on the materials and methods employed that blood was taken from patients enrolled in the Regional Haemophilia Reference Centre, Glasgow, between December 1983 and July 1984.<sup>294</sup> Professor Forbes agreed that the samples that were sent for HTLV-III antibody testing were taken from patients between those dates. There were other samples from the same patients going back to 1979 and they were later able to use the samples to determine dates of seroconversion.

**33.203** When asked if the patients were told that their blood was being tested at this time, Professor Forbes said:

I think that the answer would be probably not at that time. It's difficult to remember but this was very much a moving situation and the whole question of consent at that time was very woolly. Certainly later on it tightened up immensely and has changed even more since then. So I don't think that we would be asking for consent for storing samples but they might be told that they were being stored. So I'm very unclear as to when all these things happened.<sup>295</sup>

**33.204** Questioned further, Professor Forbes said that he was 'quite sure' that patients were not asked for their consent to be tested. He said:

I don't think that at that time there was any concern about consent because we assumed that people would want to know about what was happening and what the implications of this new test would be. So I don't think that we asked for consent.<sup>296</sup>

**33.205** It is difficult to reconcile the careful practice of obtaining specific consent to take blood for the limited purpose of a preliminary investigation of immune abnormalities with the retention of the samples, without obtaining consent, for the potentially more serious exercise of testing for HTLV-III infection when a test became available. On the basis of Professor Forbes' evidence, however, and the December article, the procedure adopted in preparation for the test did not involve obtaining patient consent. If the timetable for collection was as described above, the dispatch of samples to Dr Gallo's laboratory could have happened in or soon after July 1984. Professor Lowe was unable to assist as he was on secondment at the material time. He told the Inquiry that he was not involved in collecting samples from patients or sending them to the laboratory for HTLV-III testing.<sup>297</sup> His first exposure to the study which was published in *The Lancet* in December 1984 was when he read the draft paper.<sup>298</sup>

<sup>296</sup> Ibid page 122–123

<sup>297</sup> Professor Lowe – Day 40, page 26

<sup>298</sup> Ibid page 24

**33.206** The next witness who might have assisted in providing a date for Dr Gallo's investigation was Dr Patricia Wilkie, a researcher working at the GRI. In 1982 she was engaged in a study of the social and psychological implications of adult polycystic kidney disease and the implications for counselling.<sup>299</sup> She initially told the Inquiry that she thought that she had begun working with Professor Forbes around March or April 1983, although she could not be sure of the date.<sup>300</sup> She had found boxes of cuttings from newspapers and academic journals about HIV dating from 1983 onwards, which, she thought, showed that she was thinking about HIV at that stage, but accepted that she might have begun working for Professor Forbes in early 1984.<sup>301</sup>

**33.207** Dr Wilkie said that Dr Forbes contacted her and asked her to help with counselling haemophilia patients about AIDS.<sup>302</sup> She said that he had wanted her to work with him for some time but that she had been reluctant to do so because she was much more interested in diseases that were transmitted in an autosomal dominant way, rather than haemophilia which had been well-researched.<sup>303</sup> However, she said that there was an emerging realisation at this time that it was possible that a new virus, then called HTLV-III, might be transmitted through blood and blood products.<sup>304</sup> HTLV-III was the designation of the isolate published by Dr Gallo in April 1984. If Dr Wilkie's recollection that HTLV-III was a material factor influencing her engagement with Professor Forbes is reliable, that must have happened in or after April 1984 and no earlier.

**33.208** Her recollection was that Professor Forbes told her that he had recently returned from a haemophilia conference in the USA where it had been reported that HTLV-III had been found in the blood of some patients with haemophilia.<sup>305</sup> She recalled that he told her that he had brought back some testing kits from the USA which were not yet licensed but which could test for the presence of HTLV-III in the blood. She said that Professor Forbes had told her that he had anonymously tested the blood samples of a couple of patients with haemophilia and discovered that both samples were HIV-positive.<sup>306</sup> She added in oral evidence:

This is what he told me, and that he had realised that this should not go any further and that's why he phoned me ....

I was already a member of a research ethics committee in Edinburgh and I had a very great interest in ethics and how things should be done and consenting people and transparency, things that are still not quite with us.<sup>307</sup>

**33.209** Dr Wilkie said that the reason that Professor Forbes had contacted her was because he was agitated about the test results. He wanted her to use her skills to help his patients: to establish what people with haemophilia knew about HTLV-III, whether they knew about the existence of the virus and whether the patient thought that they may be affected. He also wanted her to find out if the patients would like to be tested for the virus if a test was available.<sup>308</sup>

<sup>306</sup> Ibid

<sup>307</sup> Dr Wilkie – Day 32, pages 18–19

<sup>308</sup> Dr Wilkie's statement [PEN.016.1297] at 1298

**33.210** Professor Forbes told the Inquiry that he did not think Dr Wilkie's recollection about testing with a US testing kit was correct. He said that he certainly did not bring anything back from the United States in his hand but he was sure that they had some connection in which tests were provided to them.<sup>309</sup> Asked if it could be the Melbye tests that he and Dr Wilkie discussed he thought that that was possible although he had no recollection of the discussion.<sup>310</sup> When he gave this evidence, he was unaware of Dr Froebel's evidence and had not then deferred to her version of events. Professor Forbes also explained that he would not personally be able to do a test like that.<sup>311</sup> He said that the initial samples were all labelled as he felt it was important to know who tested positive as action would require to be taken on the basis of the results.<sup>312</sup>

**33.211** Professor Lowe could not recall the precise month that Dr Wilkie came to the haemophilia unit but thought that she was coming regularly and speaking to the patients by the beginning of 1985. He said that she came to all the clinics and was always around and tried to see all patients who had been treated with blood products and were therefore at risk of having a positive result. She was very dedicated and made herself fully available to all patients, partners and relatives. He said that she spent a lot of time, particularly in 1985, discussing the implications of HIV test results.<sup>313</sup>

**33.212** Dr Wilkie explained that she was involved in two interconnected projects. The initial project was funded by the Scottish Home and Health Department (SHHD) and administered by Ivana Markova at Stirling University,<sup>314</sup> to establish what patients knew about the genetics of haemophilia, what treatments the patients thought were available and what patients and their families knew about infections associated with haemophilia treatment and what could be done about them.<sup>315</sup> Dr Wilkie told the Inquiry that she, Professor Forbes and Ivana Markova drafted the research proposal<sup>316</sup> although Dr Wilkie does not appear to be named on the documentation. She said that, when the project started, patients had not been tested (apart from those subjected to the initial tests) nor had they been informed of the availability of tests, to the best of her knowledge, and it was not until a little later on in the project that a decision was made by Drs Forbes and Lowe that the patients should be told that tests were available and that they should be tested.<sup>317</sup> After the Oral Hearings the Inquiry received more information from Dr Wilkie in a letter dated 7 August 2012. In it she said that she did not start interviewing patients until late summer 1985 and when she did start interviewing, none of the patients had been told their test results. In addition, she was not told of their results until she had completed the interviews.<sup>318</sup> It seems likely that Dr Wilkie started work on the HIV project in early 1985.

**33.213** Gradually, Dr Wilkie's role as a counsellor took over from her role as a researcher. She met patients both individually and with their partners or families. She would discuss the implications of being tested for HTLV-III and there being a positive result as well as the

<sup>317</sup> Ibid page 22

<sup>318</sup> Letter from Dr Wilkie to the Inquiry Team dated 7 August 2012 [PEN.019.1473]

implications of not taking the test. This was done as part of the research interview, prior to testing being carried out.<sup>319</sup>

**33.214** When asked to expand on how an interview would proceed, Dr Wilkie said:

There was a schedule, which I sent in actually, and one would ask them first of all how haemophilia had affected them in their life, what were their fears ....

....

One would discuss the implications if they were tested, the implications for their partner, or partners ....<sup>320</sup>

Dr Wilkie went on to say:

[O]nce I collected this information I fed this back to Dr Forbes – that these patients had been seen, this is what they knew and then there was a discussion about testing, that this patient was happy to be tested, that patient wasn't .... There were one or two who didn't want immediately to be tested.<sup>321</sup>

**33.215** Asking whether patients wanted to have a test, and counselling them about the implications of being tested, whatever the result, was a vital part of Dr Wilkie's work. If a patient told her that they did not want to be tested she would inform Professor Forbes and that information would go into the patient's notes so that their wishes were known.<sup>322</sup>

### *Practice in Glasgow and south west Scotland: Yorkhill*

**33.216** The position at Yorkhill is unclear. Neither Professor Hann, Head of Department of Haematology 1983–87, nor Dr Pettigrew, a part-time Clinical Assistant in Haematology 1980–89, could recall who organised blood testing there. It was not possible for the Inquiry to ascertain how this testing took place.

## **Communication of the results of HTLV-III testing**

### *The evidence of patients*

**33.217** The majority of witnesses who gave statements to the Inquiry did not know that they had been tested and did not consent to being tested for HIV before they were diagnosed with the virus. The patient or relative witnesses who gave evidence about the effects of their own or their relative's infection with HIV told the Inquiry of the circumstances surrounding their own or their relative's diagnosis with HIV. 'Christine' found out that her son 'John' had HIV when she attended a routine clinic appointment at Yorkhill Hospital in about 1984 or 1985.<sup>323</sup> 'Amy' was told by her son's GP in about 1986 that her son 'Luke' had acquired HIV from a blood transfusion.<sup>324</sup> Frances' father 'James' was told by Professor Ludlam that he had HIV on 21 December 1984.<sup>325</sup> Elaine's husband 'Brian' arranged an appointment in December 1986 with the Haematology Department of the RIE so that he, his wife and his son could be tested for the virus. He found out that

<sup>325</sup> Ibid at paragraph 5.127

he had the virus when he returned to the department for the results of these tests that same month.<sup>326</sup> 'David' was told by Professor Lowe at the Glasgow Royal Infirmary at a specifically arranged appointment on 2 December 1985 that he had acquired HIV.<sup>327</sup> His diagnosis with HIV is discussed in more detail in paragraph 33.325. 'Mark' did not find out that he had acquired HIV until January 1991 when Professor Ludlam told him at a clinic appointment.<sup>328</sup> The circumstances surrounding the communication of Mark's test results to him are discussed at paragraphs 33.304 to 33.307. 'Stephen', who was treated for haemophilia at a regional hospital, was told he had acquired HIV by the consultant treating him there in February 1986.

### Meeting in November 1984

**33.218** On 29 November 1984, a meeting was convened of Scottish Haemophilia Directors, SNBTS representatives and SHHD personnel to discuss the implications of the test results thus far obtained.<sup>329</sup> It was expected that there would be a UK-wide meeting on 10 December. Professor Ludlam intimated the finding of anti-HTLV positive results in 16 patients treated exclusively with SNBTS Factor VIII concentrate. Professor Forbes described the findings in the Glasgow patients and said that a comparative study of infection in Glasgow and Denmark would soon be published in *The Lancet*. Professor (then Dr) Brenda Gibson reported that five out of 10 patients already tested at Yorkhill were HTLV-III antibody positive. The minute noted:

Views were exchanged on the very difficult ethical problems which had arisen. These included whether patients and patients' relatives should be informed and perhaps subjected to needless worry; whether publicity additional to that already provided should be given, and how directors should respond to direct enquiries or requests for advice. The chairman [Dr Bell] advised members that ministers had been informed and that SIO had been briefed. While a press statement would not be issued by the Department at present any enquiries would be answered. It was agreed that every effort should be made for patients to have the situation explained to them before the impending publicity.<sup>330</sup>

**33.219** The problem existed in haemophilia centres throughout the UK. On 10 December 1984, as anticipated at the 29 November meeting, there was a meeting of Haemophilia Reference Centre Directors at the BPL, Elstree.<sup>331</sup> At that stage, testing had not been carried out in every centre. The notes of the meeting record that the chairman, Professor Bloom, said, in summarising the discussion, that testing should be instituted as soon as possible. It was also noted that:

A long discussion took place on whether persons found to be +ve were to be informed. Several differing views were expressed. It was agreed that each clinician would decide for each case depending on the facts of the case but in general to provide information if asked for.<sup>332</sup>

<sup>332</sup> Ibid [SNF.001.3850] at 3853

After further discussion:

It was agreed that haemophiliacs should all be given the same advice with selective advice being given based on the results of HTLV III testing.<sup>333</sup>

**33.220** In his summary, Professor Bloom repeated the view that information on test results should not be given automatically but only if asked for.<sup>334</sup> It is significant that, at this stage, the Reference Centre Directors did not acknowledge an overriding ethical obligation to inform patients: it was left to the discretion of the individual director.

### ***Meeting of 19 December 1984***

#### **Background**

**33.221** By this time, no steps had been taken in Edinburgh or Glasgow to inform patients who had been tested of their results. On Tuesday 11 December 1984, the day after the meeting, Professor Ludlam received a telephone call from a reporter at *The Yorkshire Post*.<sup>335</sup> The reporter appeared to have all the details about what was then known of the seroconversions in Edinburgh. It is not clear how the reporter obtained these details but it appears that they may have been leaked following the meeting of Haemophilia Reference Centre Directors on 10 December.<sup>336</sup> The reporter wanted to speak to Professor Ludlam about the story and indicated that he intended to publish it. Professor Ludlam agreed to meet with the reporter the following day.<sup>337</sup>

**33.222** On the evening of Tuesday 11 December 1984, Professor Ludlam telephoned Dr Bell at the SHHD. The call was reported in a note by Dr Bell written the next day:

I had phone calls last night from Dr McClelland, Dr Ludlam and Dr Cash (in that order) letting me know that that there is likely to be publicity in the Yorkshire Post, tomorrow, relating to the Edinburgh haemophiliacs with HTLV-III antibodies attributable to contamination of a Scottish batch of factor VIII. It has to be presumed that this has been leaked by one of the English haemophilia directors involved in last Monday's meeting of the UK Haemophilia Reference Centre Directors.

One of Lothian [Health Board's] Press Officers has been in touch with SIO. You may wish to discuss what should be the Department's response to this development. I understand that Dr Cash has also spoken to you direct.<sup>338</sup>

**33.223** On Wednesday 12 December 1984, the reporter travelled to Edinburgh and met Professor Ludlam. Professor Ludlam told the Inquiry that he begged the reporter not to publish the story as he felt it was no way for the patients to find out. He said that the reporter thought it was a scoop and was very keen to publish and that he had to negotiate fairly hard to delay publication for one week to give him time to organise a meeting for the patients. He promised that the information would not go out to any other newspaper in the meantime.<sup>339</sup>

<sup>339</sup> Professor Ludlam – Day 35, page 111

**33.224** Having negotiated the extension, Professor Ludlam telephoned Dr Bell again on 12 December 1984 to inform him of the development. Dr Bell appears to have interpreted the information from Professor Ludlam as an indication that ‘the haemophilia consultants’ intended to hold a meeting. The second part of Dr Bell’s note of 12 December 1984 reads:

Since dictating the above Dr Ludlam has informed me that the Yorkshire Post journalist has agreed to postpone his report until Thursday, 20 December. This will enable the Haemophilia Consultants to call a meeting of haemophilia patients to explain the situation. In view of this development I advise that SHHD should not publicise this matter before the patients themselves have been informed professionally.<sup>340</sup>

**33.225** Professor Ludlam explained that a meeting was called because ‘[w]e thought this was the quickest and most open way to start to inform the patients’ about the situation.<sup>341</sup> The purpose of the meeting was ‘to inform patients that HTLV-III tests had been carried out and that some patients were positive for HTLV-III antibody and to tell patients what we knew about AIDS’.<sup>342</sup> He acknowledged that such a meeting was not ideal for communicating the test results: ‘It’s a very public place, a meeting. People might be quite anxious about what was being said, quite concerned, and there is not much privacy in a meeting with lots of other people’.<sup>343</sup> He told the Inquiry that, had *The Yorkshire Post* not taken an interest in the story, the meeting would not have taken place at the end of December 1984. Rather, he would have devised another means by which patients would have been informed. He said a meeting ‘would not be my first choice, given a completely blank sheet and without other constraints’.<sup>344</sup>

**33.226** By the time *The Yorkshire Post* contacted Professor Ludlam, he had been in possession of some patients’ results for almost two months, the first test results having been received at the latest on 26 October 1984. No steps had been taken to inform the patients prior to contact from *The Yorkshire Post*. Professor Ludlam told the Inquiry that was because he was still ‘assessing the situation’.<sup>345</sup> Professor Forbes had results from Dr Gallo at the latest in early October, having regard to the time required to prepare and revise the article published in *The Lancet* in December, but possibly earlier. He too had taken no steps to inform patients, although it appears that he had engaged Dr Wilkie to counsel patients.

### The invitation to attend a meeting

**33.227** On 12 December 1984, a letter was sent to all patients registered at the Edinburgh Haemophilia Centre. The terms of the letter were as follows:

Dear Patient/Parent

There has been much publicity in the press and television about the HTLV III virus and AIDS. Dr Forbes, Director of the Glasgow Haemophilia Centre, and I are holding a meeting to discuss with patients some of the anxieties and issues that have been raised. You, along with a member of your family are cordially

<sup>343</sup> Professor Ludlam – Day 35, page 117

<sup>344</sup> Ibid page 116

<sup>345</sup> Ibid page 115

invited to this meeting which will be held in the Large Surgical Theatre, Royal Infirmary, Edinburgh, on Wednesday, 19<sup>th</sup> December at 7:30pm.

Dr Forbes and I will each speak for a few minutes on AIDS, Haemophilia and Blood Transfusion. We shall then open the meeting for questions and general discussion. If you do not wish, or are unable to attend the meeting, but would like to talk to me, or another member of the Haemophilia team, we should be delighted to see you by appointment with my secretary.<sup>346</sup>

**33.228** Professor Ludlam thought that he had drafted the letter. His understanding was that letters had been sent out from each of the other haemophilia centres – Glasgow Royal Infirmary and Yorkhill in the west of Scotland and Dundee, Aberdeen and Inverness in the east – and that all of the haemophilia patients in Scotland were invited to the meeting. In the case of the east coast Haemophilia Centres, Professor Ludlam thought it likely that he had sent copies to each of the centres, possibly by fax, and asked them to send out something similar. He did not specifically recall doing so but was sure that was the course of action he would have taken.<sup>347</sup>

**33.229** In the case of the GRI, Professor Ludlam told the Inquiry that Professor Forbes would have written to his own patients. Professor Ludlam thought that he would have given Professor Forbes details of the venue and left the rest to him.<sup>348</sup> Professor Ludlam could not say with any certainty that there were any Glasgow patients at the meeting. He told the Inquiry that there were quite a lot of people that he did not recognise at the meeting and he assumed that they had come from Glasgow or somewhere else in Scotland. By a process of elimination he concluded that patients from outwith Edinburgh had attended the meeting.<sup>349</sup>

**33.230** Professor Forbes said in his statement that he thought that the meeting was held to inform a group of patients from Edinburgh about what was happening with the virus and the implications thereof.<sup>350</sup>

**33.231** Professor Hann and Dr Pettigrew from Yorkhill Hospital were asked if they recalled sending invitations to the meeting to the parents of their patients. Professor Hann had no recollection of the meeting being held and did not remember being asked to write to any of the parents of his patients inviting them to the meeting.<sup>351</sup> Dr Pettigrew also had no recollection of the meeting in Edinburgh, although she thought that a meeting had been held at the Glasgow Royal Infirmary to inform haemophilia patients about the situation regarding the transmission of AIDS through blood products.<sup>352</sup>

**33.232** The evidence of events at this crucial period is again confused. Professor Ludlam remembers the meeting as a joint arrangement, involving Professor Forbes and himself among others informing Scottish patients of the outcome of investigations to date. Professor Forbes remembered it as an Edinburgh exercise, in relation to which he was 'neutral'. None of the evidence heard by the Inquiry would have suggested that Professor Ludlam had been alerted to any preparations Professor Forbes already had in hand for dealing with his own infected patients.

<sup>351</sup> Professor Hann – Day 31, pages 60–62

<sup>352</sup> Dr Pettigrew – Day 20, pages 68–69

**33.233** The meeting was held in the large surgical lecture theatre at the RIE. It started at 7:30pm and ran for about an hour to an hour and a half.<sup>353</sup> The Inquiry has been unable to establish even an approximate number of patients and relatives who attended the meeting because there is some discrepancy in the evidence. It is clear, however, that fewer people attended than Professor Ludlam had anticipated. Professor Ludlam said:

I thought a lot of people might come. As you know, there are about 400 people with haemophilia in Scotland and if each brought a friend, relative or spouse, that was potentially 800 people ....

I had reserved two large lecture theatres, anticipating that we might get a large number of people and if we had have done so, Dr Forbes would have spoken in one and I would have spoken in the other, and Dr McClelland would have spoken in both ....

But we had a smaller number. So they all fitted into the large surgical lecture theatre in the Royal Infirmary.<sup>354</sup>

**33.234** He said that he, Professor Forbes and Dr McClelland all spoke at the meeting.<sup>355</sup> Mrs Geraldine Brown, a social worker, also attended the meeting in a listening capacity and did not speak.<sup>356</sup> Professor Ludlam thought that there were between 30 and 40 people there.<sup>357</sup> Mrs Brown thought that there were between 50 and 100 people there.<sup>358</sup> Professor Forbes thought that there were around 20 people at the meeting but could not be sure.<sup>359</sup> Dr McClelland could not recall how many people had attended the meeting.<sup>360</sup> The attendees were spread out, with pairs and small groups of people sitting together and some people sitting alone.<sup>361</sup> The group of patients and their families was, in any event, much smaller than Professor Ludlam had anticipated on his approach to it as a Scotland-wide exercise.

#### *Order of speakers at the meeting*

**33.235** On 10 January 2012, the Inquiry obtained a statement from the wife of a haemophilia patient who was given the pseudonym 'Witness A'.<sup>362</sup> She attended the meeting and took handwritten notes which have been provided to the Inquiry.<sup>363</sup> In her statement she explained that she was accustomed to taking notes during meetings as a result of her work. The notes taken by Witness A indicate that Professor Forbes spoke first followed by Professor Ludlam. Dr McClelland is not mentioned in the notes, although it is clear from his own evidence and the contemporaneous newspaper reports that he did speak. The notes run to four pages and it appears that Dr McClelland's contribution is recorded at some point on pages three and/or four. It is not possible to be certain where it begins or ends.

<sup>362</sup> Statement of Witness A [PEN.018.1367]

<sup>363</sup> Ibid [PEN.018.1367] at 1369. Unfortunately, because these notes were found after Professor Ludlam, Professor Forbes and Dr McClelland had given evidence they did not have an opportunity to comment on them.

### ***What was said at the meeting***

**33.236** The Inquiry was fortunate to receive these contemporaneous notes of the meeting. They represent the most reliable evidence of statements made, although there will be omissions from the witness's record. It may even be that, as the wife of an Edinburgh patient, she did not record statements relating only to Glasgow. The Inquiry cannot know. From Witness A's notes, Professor Forbes appears to have spoken about the number of people infected in the UK and worldwide, the immune function studies ('tested when visiting hospital'), and the helper cell depletions and skin tests carried out by haemophilia centres. He referred to the fact that further investigation of supposed immune deficiency would be carried out on asymptomatic patients.<sup>364</sup>

**33.237** From the notes taken by Witness A, Professor Ludlam appears to have told the meeting that heat treating Factor VIII killed the virus and that the virus could be transmitted by semen, needle stick injuries, blood, or dental treatment.<sup>365</sup>

**33.238** He also made a number of recommendations for patients and their families:

- 1) Make up own & administer own factor VIII

IX

- 2) If not family wear gloves and aprons
- 3) Cinbins [for disposal of needles and other equipment]
- 4) Protective sheaths
- 5) Close members of family don't give blood<sup>366</sup>

**33.239** On the third page of her notes, Witness A has noted that the following was said:

- 1) [he was] prepared to inform if have antibody
- 2) Not having the antibody does not mean you have not been exposed to the virus 3–4 years for implications of antibody to become known<sup>367</sup>

**33.240** The notes continue as follows:

Link HTLV3 & AIDS does not mean  
cause & effect  
State of ignorance – Research going  
very fast  
Cryoprecipitate made from smaller pool  
but not as effective  
Virus easy to kill  
Genetic engineering of factor VIII  
far away yet – not made from  
plasma from Gene therefore No chance of getting any virus  
90% USA antibody

---

<sup>364</sup> Statement of Witness A [PEN.018.1367] at 1369

<sup>365</sup> Ibid

<sup>366</sup> Ibid

<sup>367</sup> Statement of Witness A [PEN.018.1367] at 1369

33% England  
<10% Scotland<sup>368</sup>

From the references to the future of haemophilia therapy and to rates of infection, it appears reasonable to deduce that all of the above represents Professor Ludlam's contribution.

**33.241** On the final page, the following is recorded:

Science Correspondent – Observer & Times  
fact sheet being sent out to all Haemophiliacs  
Batches            1 or several batches  
half developed antibody  
What are your plans for heat treating  
factor IX – technically more difficult  
1/3 less patients get HTLV3 antibody  
BTS procedure – less likely to be with factor IX  
Mild Mod Haem A treat DDAVP  
Live Virus HTLV3 used to test for Antibody  
younger shorter incubation  
older months – years  
Saliva – Very late stages of disease  
Not transmitted readily<sup>369</sup>

From the references to heat treating, it is possible that these remarks were made by Dr McClelland but it is not possible to be sure. The Inquiry also heard evidence from Professors Forbes and Ludlam, and Dr McClelland about their recollection of the meeting.

### Professor Forbes

**33.242** Professor Forbes found it very difficult to recall any details of the meeting. He had 'a major blank' in parts of his recollection.<sup>370</sup>

**33.243** Professor Ludlam admitted that he could not actually recall the detail of what Professor Forbes had said.<sup>371</sup> He thought it likely that Professor Forbes would have told the meeting some of the background to HTLV-III (ie that a probable virus that caused AIDS had been identified) and explained that a new test for HTLV-III antibody had been developed and that samples from patients in both Edinburgh and Glasgow had been tested and found to be antibody positive.<sup>372</sup> Professor Ludlam thought that Professor Forbes would then have talked about the findings in Glasgow and that he would have talked about his findings in Edinburgh.<sup>373</sup>

<sup>371</sup> Professor Ludlam – Day 35, page 130

<sup>372</sup> Ibid pages 130–131

<sup>373</sup> Ibid Page 130

**33.244** Professor Ludlam thought that Professor Forbes would have explained what was known about the implications of being antibody positive and what the chance was of developing AIDS. At that time it was thought that the risk of progression to AIDS was in the order of one in 500 or one in 1000. One of the important messages that they were trying to convey at the meeting was that patients' sexual partners could be at risk and that all patients should use condoms during sexual intercourse. Professor Ludlam thought it likely that Professor Forbes had addressed this issue. Professor Ludlam's recollection was that Professor Forbes dealt with the generalities of anti-HTLV-III testing and positivity.<sup>374</sup>

### Professor Ludlam

**33.245** Professor Ludlam thought that he would have spoken for approximately ten minutes. He did not speak from a prepared script or notes.<sup>375</sup> He told the Inquiry that he would have addressed what had been happening in Edinburgh: that blood samples from patients in Edinburgh had been tested for HTLV-III antibody by Professor Tedder and that some samples had tested positive. He thought that he would also have told the meeting that it appeared that a single batch of Factor VIII was responsible for the infections in Edinburgh but that other people might also be antibody positive:

It was a time of great uncertainty and we were very careful also to convey the message that if you were antibody negative, you weren't necessarily free of HTLV-III infection, and so the advice was for everybody to consider they might be infectious, everyone with haemophilia might be infectious, and ... the safety advice applied not only to the possibility of sexual transmission but if there was spillage of blood, it should be cleaned up carefully with gloves on and using dilute bleach to sterilise the surface.<sup>376</sup>

**33.246** Professor Ludlam said:

[T]he very clear message given out was that we hoped that patients would come and see us and ask about their situation. We were keen to discuss it with people individually. That was not just the people who were HIV positive. They didn't know who they were. We were keen to see everybody.<sup>377</sup>

**33.247** He said that he was keen for people to make appointments to see him to discuss whether there was an anti-HTLV-III result for them and whether they would like to know the result. He recalled telling the meeting that he would give patients their results if they wanted to know.<sup>378</sup> He could not recall, but thought it likely that he would have told the meeting how many patients had tested positive for the antibody. He said that he and his colleagues were there to give out any information they had and, as there was a number available, he would have said something like: 'So far it looks like there were 15 or 16 people' who had antibody to the virus and that it had arisen from Scottish product.<sup>379</sup>

<sup>377</sup> Ibid page 134

<sup>378</sup> Ibid pages 135–135

<sup>379</sup> Professor Ludlam – Day 36, page 22

## Dr McClelland

**33.248** Dr McClelland told the Inquiry that the purpose of his attendance at the meeting was twofold. In the first instance he was there in a very specific capacity as representing the organisation which had manufactured the product believed to have been the source of infection, the SNBTS. There was also a general knowledge element to his presence at the meeting: by the time of the meeting he had been actively involved in work around AIDS and was relatively well informed about AIDS generally and the issues surrounding the interpretation of HTLV-III tests results.<sup>380</sup>

**33.249** Dr McClelland could not recall what he spoke about at the meeting, although he thought it likely that he would have spoken in terms comparable to patient information leaflets about what he understood at the time from his own knowledge of the situation.<sup>381</sup> He referred to an article in *The Edinburgh Evening News* on 21 December 1984<sup>382</sup> and confirmed that the information contained in that article was the sort of information that he would have given in respect of what was understood at the time about the nature of the virus, the nature of the test and the likely prognosis for people who were found to be antibody positive. He thought that he would also have told the meeting about the measures that the SNBTS, as a manufacturer, was taking to try to minimise future risks in terms of donor selection and plans to introduce routine donor testing.

## Question and answer session

**33.250** After Dr McClelland had finished speaking, Professor Ludlam's recollection was that Professor Forbes as the chairman invited questions and Professor Ludlam, Professor Forbes and Dr McClelland answered them depending on what the questions were. The question and answer session went on until all the questions were exhausted – perhaps half an hour or three-quarters of an hour.<sup>383</sup>

**33.251** Dr McClelland also recalled the question and answer session at the end of the meeting:

[T]here were some questions from patients. I think they were probably fairly muted because I think they were probably in a state of shock and having considerable difficulty in orientating themselves. Partly because of the nature of the information, partly because it was a very strange spot. It was a very strange situation altogether. So I think it would have been very difficult for patients to really absorb what was happening at that time.<sup>384</sup>

**33.252** Professor Ludlam and Mrs Brown described a feeling of dismay among the patients. Professor Ludlam told the Inquiry that there was 'surprise and I think some dismay' that individuals who had been treated exclusively with SNBTS product appeared to have been exposed to the virus.<sup>385</sup>

### Dr Alison Richardson's evidence

**33.253** Dr Alison Richardson, Clinical Psychologist, began seeing haemophilia patients from 1988 onwards. In her statement to the Inquiry she said:

Most of the patients I subsequently saw, after being referred to me by Dr Ludlam, recall being asked to come to an urgent meeting with Dr Ludlam. I am not exactly sure when this meeting was but I presume it was after these blood test results came back in about 1985. I think Dr Ludlam invited all the patients with haemophilia and not just those who were infected with HIV. Dr Ludlam wanted to warn them about HIV in the blood supply. I think that Dr Ludlam intended to persuade all the people with haemophilia to have a test for HIV. I was not present at that meeting, since this was before I had taken up my post. From what I have heard from the patients I spoke to subsequently, Dr Ludlam told them that some people with haemophilia in Scotland were infected with HIV. Two of my patients said that they were told at the meeting to use condoms when having sexual intercourse with their wives. From what I have heard from these two patients, the general feeling leaving that meeting was 'well, thank goodness, I don't have it, because if I had, he would have told me'. So, they left the meeting thinking that they did not have HIV.<sup>386</sup>

**33.254** In fact, these were two patients who had tested positive. Professor Ludlam was referred to this section of Dr Richardson's statement and was asked whether he would accept that these two patients did not appear to have received the message that they might be positive. He said:

They have not synthesised the information that was available to them, in that they ... would like to believe that they were in the larger group, who were anti HTLV-III negative.<sup>387</sup>

**33.255** Professor Ludlam told the Inquiry that he was clear that the message that he had given at the meeting was: 'you might be positive'.<sup>388</sup> He said that he had emphasised that, if patients wished to know their test results, they were to contact their haemophilia consultant to discuss their individual situations.<sup>389</sup> He said that the other side of that was that the majority of patients were in fact negative. As the majority of people had tested negative, Professor Ludlam believed that this may have influenced how attendees at the meeting assessed their own situation:

So there were a lot of people who were negative and more people actually who were negative than positive. So a patient might have gone away with the message, "Oh, well, I'm likely – because there were more people negative than positive, I'm likely to be one of the lucky ones." It's how one accepts bad news. We always like to think, to begin with, that we are on the winning side, if I can put it that way.<sup>390</sup>

---

<sup>386</sup> Dr Richardson's statement [PEN.016.1284] at 1288

<sup>387</sup> Professor Ludlam – Day 36, page 34

<sup>388</sup> Ibid page 30

<sup>389</sup> Professor Ludlam's note on long term safety monitoring for transfusion-transmitted infections [PEN.012.0351] at 0355

<sup>390</sup> Professor Ludlam – Day 36, page 31

**33.256** It was suggested to Professor Ludlam that the fact that patients were at risk didn't appear to have been effectively communicated to the patients. Professor Ludlam replied:

I would see it differently. They went away appreciating the need to use condoms. So they must have picked up that there was a possibility that they had got HIV or HTLV-III. That was why we were saying, "You have to use condoms" ....

I appreciate that they may not have seen it that way.<sup>391</sup>

**33.257** Professor Ludlam noted that patients were given condoms when collecting their concentrates from the Haemophilia Centre and that additional supplies, in plain paper bags, were placed on a shelf in the waiting room for patients to help themselves to.<sup>392</sup>

#### **Mrs Geraldine Brown's evidence**

**33.258** Mrs Brown told the Inquiry that, on the basis of what she recalled of the meeting, it would have been clear to anyone who attended that there was a group of patients infected in Edinburgh, that they might be a member of that group and that if they wished clarification of that, to know whether they were in the infected group and had tested positive, they had to approach Professor Ludlam and ask.<sup>393</sup>

**33.259** It was suggested to Mrs Brown that there were people at that meeting who did not appreciate that they would only be told their test results if they asked for them. In response to that, Mrs Brown said:

I think giving information to people of this kind, people who are in this situation, it can't just be a one-off thing. I think all sorts of things interfere with the way people process the information that you give them, which is why it was really important to have written information after the meeting, which people could read at their leisure and refer to ....

[I]t is difficult to give people information about such issues. I was ... a disinterested observer in the sense I wasn't personally involved. For me the information was quite clear but I can see that for other people perhaps it wasn't.<sup>394</sup>

**33.260** *The Yorkshire Post* published its article on Thursday 20 December 1984. In relation to the situation in Edinburgh it stated:

Dr Christopher Ludlam, a consultant haematologist and director of the haemophilia centre at Edinburgh Royal Infirmary, admitted yesterday that antibodies to the suspected AIDS virus had been found recently in 16 of his patients who were receiving only the NHS material. He told the *Yorkshire Post*:

'We picked up the HTLV 3 antibodies as part of a research project. We had hoped they would not be there. What this means is that these patients have been exposed to the virus.

We know it was not from an American blood product – because all these patients have been treated only with Scottish Factor 8. They may or may not still have the virus – it is something we cannot tell.

---

<sup>391</sup> Ibid page 34

<sup>392</sup> Professor Ludlam – Day 39, Page 101

<sup>393</sup> Mrs Brown – Day 34, page 75

<sup>394</sup> Ibid pages 75-76

This amounts to evidence that the material in Scotland has been contaminated with HTLV 3 and this must have come from a donor or donors who have the virus.

I can categorically say that to date there have been no cases of AIDS in Scotland attributable to Scottish Factor 8. My patients are all clinically well at the moment.

On present evidence it would appear that although AIDS may be caused by HTLV 3 only a small percentage of people who become infected actually develop the disease'.<sup>395</sup>

**33.261** The article went on to say:

News of the positive testing was broken to haemophiliacs from Edinburgh and Glasgow at a meeting last night. They were told collectively that some of them were carrying AIDS antibodies.

Dr Ludlam said: 'If individual patients want to know where they stand I shall tell them'.

Patients were strongly advised that from now on they should wear contraceptive sheaths during intercourse to protect their partners from danger.

They were also urged to take every precaution when making up their Factor 8 for home injections, and disposing of needles, syringes and plastic gloves.<sup>396</sup>

***Follow-up in Edinburgh***

**33.262** Following the meeting Professor Ludlam wrote to Dr McClelland about the need for precautions, in a letter dated 31 December 1984:

Dear Brian

Thank you for your letter of 12 December concerning our recent discussions about the desirability of close family members of haemophiliacs not donating blood.

As we agreed in our discussion it would be better to disseminate this information in the haemophiliac community by our existing lines of communication, rather than add these potentially high risk donors to your 'formal' list as published by the SNBTS. At the meeting of haemophiliacs on 19 December, at which you were present, this point was made clear. To make sure that the wider haemophiliac community is made aware that they should not be blood donors, we are arranging for a circular to be sent to every patient with moderate and severe haemophilia A and B.

I hope this will prevent any further donations within the Edinburgh and Glasgow areas. We are planning to send the circular to the other three East Coast Haemophilia Centres asking them to distribute it amongst their patients.<sup>397</sup>

---

<sup>395</sup> 'NHS blood carries killer AIDS virus', *The Yorkshire Post*, 20 December 1984 [SGH.002.6491]

<sup>396</sup> *Ibid* [SGH.002.6491] at 6491–92

<sup>397</sup> Professor Ludlam's letter to Dr McClelland dated 31 December 1984 [SNB.006.4686]

**33.263** Professor Ludlam also arranged for an advice sheet for adult patients and their families to be circulated.<sup>398</sup> It was sent to all patients on the Edinburgh Haemophilia Centre Register (around 170 patients) regardless of whether or not they had already been tested.<sup>399</sup> Paragraph 7(d) states: 'All relatives living in the same house with the family should refrain from giving blood. This is a simple precaution only'.<sup>400</sup> Professor Ludlam told the Inquiry that the circular was prepared in conjunction with Professor Forbes and was intended to be sent to all haemophilia patients in Scotland.<sup>401</sup> It is clear from the letter to Dr McClelland of 31 December 1984 that Professor Ludlam intended to send the circular to the other three east coast Haemophilia Centres.

**33.264** In the end, the circular was not sent to patients at the GRI. Rather, Professor Forbes seems to have incorporated parts of it into a letter which he sent to his patients on 8 January 1985, discussed below.<sup>402</sup>

**33.265** It is not clear exactly when the circular was sent out to Edinburgh patients as the document is undated. Professor Ludlam thought that it was probably sent out on 31 January 1985,<sup>403</sup> the same date on which letters were sent to GPs.<sup>404</sup> He had a recollection of all the information being sent at once. He also thought it unlikely that he would have written to the patients without first informing their GPs of that fact as he considered it only fair to make sure that GPs were forewarned before patients began going to see them. GPs were not sent a copy of the circular unless requested.<sup>405</sup> They were not given their patients' test results in these letters.<sup>406</sup>

**33.266** Professor Ludlam thought that the circular would have been sent out with a covering letter, although the Inquiry has been unable to locate a copy of such a letter. When asked for his recollection of what was in the covering letter, Professor Ludlam told the Inquiry that he thought that it would have referred to the meeting and would have said that the circular was being sent out to convey important information about AIDS to patients who had not attended the meeting. He thought that it would have mentioned that some patients had tested positive for HTLV-III in Scotland but that not all patients had been tested and that if patients would like to know the results of their test (which may or may not be available) they should make an appointment to see Professor Ludlam or to discuss the situation with Geraldine Brown.<sup>407</sup>

**33.267** Professor Ludlam thought that the circular, and in particular paragraph 6, combined with what was in his covering letter, was enough to get the message across to patients that they might be positive.<sup>408</sup> Paragraph 6 stated:

---

<sup>398</sup> Advice sheet for adult patients and families [PEN.012.0495]. At the same time a circular was also sent to parents of children with haemophilia. The only difference between these documents was that the latter did not refer to sexual activity. Professor Ludlam – Day 36, pages 47–48

## 6. What is the virus?

The virus probably responsible is called Human T-cell Lymphotropic Virus (HTLV III). Its main action is to reduce the effectiveness of a particular cell ( $T_4$  cells) in the immune process. Exposure to the virus results in the body making an antibody (HTLV III Ab) to the virus protein and this is now used as a marker of exposure to the virus. These tests are now available and will be carried out on your routine visits to your centre. About half the patients in England and about ten per cent in Scotland have had exposure and are HTLV III Ab-positive.<sup>409</sup>

**33.268** When asked why he did not make the letter more explicit, Professor Ludlam said:

I would have an obligation to inform patients of their antibody result if it was going to make a difference to either the way they lived or treatment that might be available for them. And at that time there was unfortunately no treatment available and there were some patients who clearly didn't want to know, and so, as there was no, in a sense, material gain from knowing, then it was a patient's prerogative not to know.<sup>410</sup>

**33.269** When asked why he did not simply inform all of his patients of their test results, Professor Ludlam explained that it took some time for clinicians themselves to come to terms with the results. That patients had been exposed to the virus was 'a surprise and a shock'. He added that it might have been the case that some patients would not have wanted to know their results and that, following the distribution of the circular, some patients were indeed 'hesitant' about knowing their results. In addition, there was already a great deal of stigma surrounding AIDS and Professor Ludlam believed that patients would have to consider that when deciding whether or not to obtain the results of their tests.<sup>411</sup>

## Communication of results

**33.270** Professor Ludlam thought that it was the beginning of January 1985 before patients began contacting him asking for their results. He described it as an 'ad hoc, unstructured arrangement'. Sometimes patients would come to the clinic for other reasons, for example to collect home treatment, and would ask the nurse if he was available to see them. At other times the patient would come to the clinic and the nurse might initiate a meeting by asking if the patient wanted to see Professor Ludlam.<sup>412</sup> Professor Ludlam told the Inquiry that the physical arrangements at the haemophilia centre at that time were unsatisfactory in terms of conveying results:

It's a time when we were very short of clinic space ... [A]t that time we had a single room with a small partitioned area off in one of the wards which we called our "haemophilia centre", which was for the treatment of acute bleeds, basically.

The patients were seen for their routine reviews in the general medical outpatient department. So I did not have anywhere else to see people with some degree of privacy, and I remember having to borrow rooms in one or two of the other wards [and having] to find out where there was a free room to see someone.

---

<sup>409</sup> Advice sheet for adult patients and families [PEN.012.0495] at 0496

<sup>410</sup> Professor Ludlam – Day 36, page 44

<sup>411</sup> Note of a meeting between Professor Ludlam and the Penrose Inquiry legal team [PEN.012.0774] at 0794

<sup>412</sup> Professor Ludlam – Day 36, pages 58–59

So it was unsatisfactory but I wanted to give the patients a bit of space and time and have a bit of privacy. The facility we had in ward 23, the partition wall between the waiting area and the tiny clinic room, was thin and I don't think there was even room to sit down actually in this little room. We had a couch and a filing cabinet. So I had to find other space. So it was not satisfactory but I had to make do.<sup>413</sup>

**33.271** He said that whether or not he initiated discussion about AIDS with patients attending clinics or encouraged them to ask for their results depended on why he was seeing them in the clinic. If patients came to the clinic with a specific medical issue that needed to be addressed (such as a bleed or a medical problem that required investigation) he would concentrate on that issue because that was what the patient had come for. He said that he would not have raised the topic of AIDS with patients in these circumstances because he felt that it would have been confusing for them.<sup>414</sup>

**33.272** If patients came to the clinic for a routine review appointment and he was having a more general discussion about their health (for example, how they were feeling, whether their clotting factor was working properly, whether they had been off work due to bad bleeds, etc) then he might have asked, as part of that general discussion, what the patient knew, if anything, about AIDS and taken it from there.<sup>415</sup>

**33.273** Professor Ludlam explained that he would not discuss AIDS if the patient had some other preoccupation. At a routine review without any other immediate concerns he would think about raising it with the patient but would not necessarily do so even then.<sup>416</sup> He said that he would raise the matter if he 'thought it appropriate'. He told the Inquiry:

I raised the topic with patients when they came for review, not all patients, not all the time but some of them some of the time.<sup>417</sup>

**33.274** Subsequently, large-scale local testing for HIV was instituted from early in 1985. This is discussed separately below.

### *Follow-up in Glasgow*

**33.275** As noted above, Professor Ludlam's circular was not sent to patients at the GRI. Instead, a letter, signed by Professor Forbes and Professor Lowe and dated 8 January 1985, was sent to all patients registered at the West of Scotland Haemophilia Centre.<sup>418</sup> Professor Lowe described the letter as an 'update' for patients in light of recent developments. He explained that the purpose of the letter was, firstly, to inform patients that there was an apparent HIV problem in the Scottish haemophilia population and, secondly, to invite them to the Haemophilia Centre to discuss the matter with one of the doctors who would then, after obtaining consent, take a fresh blood sample which could be tested for HIV. He did not think that the purpose of the letter was to invite patients to the Haemophilia Centre for Professor Forbes to give them the results of the Gallo research study tests.<sup>419</sup>

<sup>418</sup> Letter from Dr Lowe and Dr Forbes to GRI haemophilia patients dated 8 January 1985 [LOT.003.4244]; Professor Lowe – Day 40, pages 44–45

<sup>419</sup> Professor Lowe – Day 40, pages 36–40

**33.276** The letter began by setting out the material background:

As you may know, there has been recent publicity in the newspapers and television concerning an increased risk of the disease known as Acquired Immune Deficiency Syndrome (AIDS) in haemophiliacs who have received treatment with clotting factor concentrates.

....

We do not yet have a blood test for the virus particle, but hope to have this within the next few months. However, we and other haemophilia centres do now have a blood test for antibody to the virus. If this antibody test is positive, this means that the person has been exposed at some time to virus particles. A positive test does not mean that the person will develop AIDS. Recent studies in England have found that about half of regularly treated haemophiliacs have positive antibody tests. We have recently tested stored blood samples from many of our patients, of whom about 10% have positive antibody tests.<sup>420</sup>

**33.277** The letter then set out what was to happen next:

Firstly, we enclose an appointment to see you. It is important that we take a blood sample from you for the virus tests, so that we can monitor virus exposure in all our patients who have received factor concentrates. We would also like to perform some skin tests which measure the body's defences against infections. At the same time we will be very happy to give further information and to answer any questions you may have about the virus and the tests.<sup>421</sup>

**33.278** Patients were advised that, if the enclosed appointment was unsuitable, they should contact the haemophilia Sister for an alternative appointment.

### Communication of results

**33.279** Professor Forbes said that his Haemophilia Centre 'always had a very open policy'<sup>422</sup> and that he took the view that his patients should be told about their test results: 'we made a firm decision that we would tell the patients what had been found in the various tests that were done and the implications thereof'.<sup>423</sup> His recollection was that patients were told as soon as practicable: 'we told them as soon as possible and we in fact had to make appointments for many of them especially and bring them in to tell them'.<sup>424</sup> With regard to the initial Gallo tests he stated that the 12 patients who had already tested positive were informed of their primary test results before confirmatory testing by Dr Edward Follett.<sup>425</sup>

**33.280** Professor Lowe recalled that at the time the draft manuscript of the December article in *The Lancet* (with the results of the 12 positive tests) was being discussed, probably around September or October 1984, Professor Forbes said that he would see the patients with positive test results and arrange counselling. Professor Lowe stated that he had 'absolutely no reason' to believe that Professor Forbes did not do so.<sup>426</sup> He described

<sup>423</sup> Professor Forbes – Day 33, page 131

<sup>424</sup> Ibid page 133

<sup>425</sup> Ibid

<sup>426</sup> Professor Lowe – Day 40, page 52

Professor Forbes as ‘an extremely open person’ who would spend hours with his patients discussing all manner of things and that he could not think of any reason why Professor Forbes would not have been open and honest with patients.<sup>427</sup> Professor Lowe was not involved in communicating the Gallo test results, however, as Professor Forbes felt strongly that, as the Consultant, it was for him to speak to the patients and tell them about the situation.<sup>428</sup>

**33.281** Professor Lowe thought that Professor Forbes had some reservations about the reliability of the Gallo test because it was a research assay and had not yet been licensed for clinical use. He recalled that Professor Forbes thought that the best thing to do was to set up properly approved tests with Dr Follett at the local regional virus laboratory, inform the initial 12 positives of their (provisional, at that stage) results, offer them counselling and arrange for further, confirmatory testing when that became available. Professor Lowe thought that it was around this time that Dr Wilkie was appointed.<sup>429</sup>

**33.282** It is clear that by October 1984, well before the meeting in Edinburgh in December 1984, Professor Forbes had initial positive results on 12 of his patients. It is likely that by then he had made at least preliminary arrangements with Dr Wilkie for counselling patients testing positive for HTLV-III. Professor Forbes was asked whether he knew that he had 12 patients who had tested positive at the time he appointed Dr Wilkie. He replied:

I’m not sure. I don’t remember the chronology of that but I knew that it was going to come that this epidemic would happen in Scottish haemophiliacs, as it did.<sup>430</sup>

**33.283** On Dr Wilkie’s evidence Professor Forbes did know that some of his patients were infected when he approached her.

**33.284** The letter of 8 January 1985 indicated that stored blood samples had already been tested, with about 10% antibody positive results (paragraph 33.276 above). To some extent – which cannot be quantified – patients’ blood samples were also being tested in Dr Follett’s laboratory in January 1985, before the development of a routine requiring prior counselling and consent. The way in which these samples were sent to Dr Follett can only be characterised from the patient’s point of view as clandestine.

**33.285** Equally, there is no reliable evidence that the results of the series of tests performed by Gallo, which from the patient’s point of view were also clearly clandestine, were ever communicated to the patients involved. How far the knowledge of the Gallo results was known within the GRI is not clear. From Professor Lowe’s evidence it appears that circulation of the information was limited, but Professor Forbes clearly knew who had been tested and what the individual results were. In the circumstances, the point of the reference in the letter dated 8 January to recent studies in England showing that about half of regularly treated haemophilia patients had positive antibody tests is not obvious. Indicating that a lower proportion of Glasgow patients was infected minimised the serious implications for the 10% of local patients who had positive antibody tests.<sup>431</sup>

<sup>430</sup> Professor Forbes – Day 33, page 126

<sup>431</sup> Letter from Dr Lowe and Dr Forbes to GRI haemophilia patients dated 8 January 1985 [LOT.003.4244]

**33.286** Communication of the results of the Gallo test series, available in October 1984, was left in the hands of Professor Forbes. Unfortunately, and as he was well aware, his recollection of the Gallo tests and matters related to them is not good. It seems likely, despite his recollection, that he did not pass the Gallo results on to the patients tested. Professor Lowe mentioned Professor Forbes' reservations about the accuracy of the Gallo tests as it was a research assay, and not yet licensed for clinical use. Dr Froebel also remarked on Professor Forbes' reservations due to the Gallo test's unregulated state. Given the life-changing effects of testing, whether the results were positive or negative, Professor Forbes might well have considered that confirmation of the Gallo tests was required prior to passing on any information to patients about their positive or negative status. His foresight in employing Dr Wilkie as an HIV/AIDS counsellor (his unit being the first in Scotland to do so) suggests that he was sensitive to the extensive ramifications of testing and, in particular, a positive diagnosis.

## **Local testing**

### *Edinburgh*

1985

**33.287** Very early in 1985 it became clear that anti-HTLV-III testing would have to be set up in many centres in the country. Dr John Peutherer, a virologist with whom Professor Ludlam had worked previously, made enquiries about setting up HTLV-III antibody testing in Edinburgh. Professor Ludlam thought that by the spring of 1985 a number of different commercial kits were under evaluation.<sup>432</sup>

**33.288** Local testing was available by the spring of 1985 and was carried out by Dr Peutherer. Professor Ludlam said that patient consent was obtained prior to all local testing if a fresh blood sample was taken.<sup>433</sup> He recalled that most of the patients tested were found to be HTLV-III antibody negative, with between five and 10 found to be antibody-positive.<sup>434</sup>

**33.289** Professor Ludlam also thought that he would probably have sent additional stored samples from those people who had already been tested by Professor Tedder, to confirm the initial result and, for those who had tested positive, to determine their date of seroconversion. He thought that this confirmatory testing had been carried out by Dr Peutherer on all of the results received from Professor Tedder. It appears, therefore, that so far as the original group is concerned (the 50–70 patients who had been tested without their consent), there may have been repeat testing by Dr Peutherer in 1985 by reference to archived material. Professor Ludlam thought that this was probably also done without their consent: the procedure continued under the original regime. He did not think that there was any other testing of patients without consent.<sup>435</sup>

**33.290** Local testing opened up the opportunity for many more individuals to be tested, not just people with haemophilia. The AIDS advisory committee in Edinburgh was established at Professor Ludlam's suggestion and held its first meeting on 19 December 1984.<sup>436</sup> Dr Peutherer told the Inquiry that subsequent testing for HTLV-III infection started

---

<sup>432</sup> Professor Ludlam – Day 36, pages 73–74

<sup>433</sup> Ibid page 90

<sup>434</sup> Ibid page 75

<sup>435</sup> Ibid pages 91–92

<sup>436</sup> Ibid page 74

in 1985 once commercial tests became available. Professor Ludlam did not carry out any HTLV-III testing in his laboratory. All testing for patients from the RIE was carried out by the Hepatitis and HTLV-III/HIV Reference Laboratory within the University of Edinburgh's virus diagnostic service. The tests used were purchased from several companies, including Abbott, Wellcome and Ortho.<sup>437</sup>

**33.291** Professor Ludlam said that early in 1985, when testing became more generally available, there were calls from many different people – particularly surgeons – for screening of all patients. The difficulties around this issue and also, for example, enquiries from insurance companies wanting to know whether someone had been tested, grew very rapidly through 1985 and led to thinking about what is now called pre-test counselling. The whole complexion of testing changed.<sup>438</sup> In 1985 Professor Ludlam drew up some guidelines for testing.<sup>439</sup> He explained:

These were fairly primitive guidelines that – I think they must have been written in 1985, probably the end of 1985, because if I remember correctly ... they don't give a definitive view about the significance of being anti HTLV-III positive.<sup>440</sup>

**33.292** Professor Ludlam thought that he had drafted the guidelines after discussion with colleagues. He said that they were primarily for staff use and were a way of focussing the minds of staff members on the important things to think about:

[T]his evolved, if you like, out of ... our realisation that it was appropriate to get consent and to think about ... whether people want[ed] to know about positive results or ... want[ed] to be tested ....

So the degree of pre-test counselling ... evolved during 1985.<sup>441</sup>

### Discussions with Mrs Geraldine Brown

**33.293** Mrs Brown told the Inquiry that she began working at the Edinburgh Haemophilia Centre in about December 1984 and started seeing patients very shortly thereafter, in January or February 1985.<sup>442</sup> She noted that, at that time, there was no physical haemophilia centre in the way that there is now.<sup>443</sup> Rather, in-patients were seen on the ward and out-patients were seen in the medical out-patients department or in doctors' offices. Mrs Brown told the Inquiry that the arrangement in early 1985 was that she would go to the medical out-patients department and meet with patients after they had been seen at the clinic to introduce herself. If patients were on the ward having treatment she would also go along and introduce herself there. She said that Professor Ludlam also made patients aware that a new social worker was attached to the unit and that she was available to see patients.<sup>444</sup>

<sup>441</sup> Ibid page 90

<sup>442</sup> Mrs Brown – Day 34, page 39

<sup>443</sup> Ibid page 30; See also Professor Ludlam's note on the development of the Edinburgh Haemophilia and Thrombosis Centre [PEN.012.0386] at 0387, where Professor Ludlam describes the 'haemophilia centre' at that time as comprising a small side room in a ward, a weekly clinic in the Medical Outpatients Department and the haemostasis laboratory. These three sites were spread across the hospital campus. A new Haemophilia Centre, with considerably better facilities, was opened in 1988.

<sup>444</sup> Mrs Brown – Day 34, pages 30–31

**33.294** Mrs Brown told the Inquiry that she often spoke to patients about whether they should ask for their tests results and what the implications were prior to them making a decision. She described some of the difficulties regarding this to the Inquiry:

It was a very different atmosphere then in terms of knowledge and patients were very aware that they were identifiable as a group, haemophiliacs were identifiable as a group ... that they were already seen in the community as people who were potentially infected with HIV.

There was concern [that] the fact that someone ... had been infected with HIV [would interfere with the] provision of services to them ... on a financial level, insurance companies' questions, mortgage lenders' questions. There were concerns about discrimination in terms of the provision of medical services. There was concern that surgeons wouldn't operate on them if they were known to be HIV [positive]. There was a kind of feeling around at the time of this great anxiety about what would happen if people knew you were HIV positive.

There was also, of course, an acknowledgement that there wasn't really any treatment going to be available to patients. So knowing that they were HIV positive, it wasn't like getting another medical diagnosis which would immediately throw in a treatment programme, because at that point there wasn't really anything being offered in terms of treatment, although anyone who was infected with HIV would benefit from being followed up medically. The haemophiliacs were being followed up anyway because they were being seen regularly at the hospital. So people were weighing up the pros and cons really of knowing that they were infected with HIV.

And also, I think, for some people – I think the way you deal with significant medical information about yourself sometimes is you don't want to know. You might just put it aside and prefer to carry on ... as you are.

So people had lots of issues that they discussed really prior to asking for the information.<sup>445</sup>

**33.295** Mrs Brown said that patients began to ask for (and were told) their HIV status during the first three months of 1985. It was a gradual process after that with more and more people asking for their results during the course of the year. She thought that by the end of 1985 most patients would have known their HIV status but that there were one or two patients who had not asked for their results.<sup>446</sup> She said:

I think the point to emphasise is that if people did not know they were infected, it was because they didn't ask. I think it was quite clear to people from the start that this information was available to them and they could have it and I think that in a sense the ball was in their hands, when they were told that a group had been infected. It was quite clear that they did need to make the approach and discuss it.<sup>447</sup>

---

<sup>445</sup> Ibid pages 39–41

<sup>446</sup> Ibid pages 44–45

<sup>447</sup> Ibid page 60

**33.296** Professor Ludlam also thought that the vast majority of his patients were aware of their HTLV-III status by the end of 1985. This included patients who had tested positive and patients who had tested negative. His recollection was that by the end of 1985 there was only a small handful of patients who were known to be anti-HTLV-III positive and who did not know their results. He thought that by the end of 1985 probably only around three to five patients would not have known their HTLV-III status.<sup>448</sup>

**33.297** Those who did not know their results by the end of 1985 fell into two categories: (i) those who were adamant that they did not want to know and (ii) those who did not appreciate that they needed to ask for their results. Professor Ludlam said that he could think of only two individuals in the second category and one individual (the witness pseudonymised as 'Mark', discussed below at paragraph 33.304) who expressly said that he did not want to know.<sup>449</sup>

## 1986

**33.298** Professor Ludlam said that in late 1985 and early 1986 the picture was gradually evolving. By that time it was becoming clearer, firstly, that patients who tested positive for antibodies to HTLV-III probably harboured the virus and, secondly, that the risk of progression to AIDS in patients who were HTLV-III positive was greater than the original estimate of one in 500 or one in 1000. There was greater confidence about what an anti-HTLV-III positive result meant, and conversely there was a bit more confidence that those who were anti-HTLV-III negative did not have the virus.<sup>450</sup> For those who had tested positive, emerging data also suggested the course of the disease might be worse than had previously been thought:

[T]he significance in terms of their prognosis was beginning to look a bit worse. There was still no treatment or no prophylaxis at this stage, nothing that could be done, in a sense, medically to improve their prospects.<sup>451</sup>

**33.299** Professor Ludlam knew the identities of those patients who were HTLV-III antibody positive but who had not received their results at the end of 1985.<sup>452</sup> Weekly multi-disciplinary meetings were held where individual patients were discussed. The meetings were attended by a core group of Professor Ludlam and his registrar; Dr George Masterton, a psychiatrist; Michelle Jones, the Haemophilia Sister; Billie Reynolds, the Staff Nurse; and Geraldine Brown. Professor Ludlam stated:

This was ... a fairly quiescent period at one level because patients were all feeling well. It was a sort of phoney war time, if I can put it that way. All the patients were well and we discussed each week who we had seen, exchanged information that seemed relevant and increasingly worried about the small number of people who ... had tested positive and didn't know.<sup>453</sup>

**33.300** Although the group appears to have been discussing patients who did not know their results during this time, no positive steps were taken to inform those patients. Professor Ludlam told the Inquiry that this approach, of not insisting that patients know their results, did not change at this time.<sup>454</sup>

<sup>448</sup> Professor Ludlam – Day 39, page 135

<sup>449</sup> Ibid pages 135–136

<sup>450</sup> Professor Ludlam – Day 36, page 67. Notwithstanding what is recorded in the transcript, the Inquiry is of the view the 'weren't' recorded at line 23 should be 'were'.

<sup>451</sup> Professor Ludlam – Day 36, page 69

<sup>452</sup> Ibid page 67

<sup>453</sup> Ibid pages 68–69

<sup>454</sup> Ibid page 70

**33.301** The feeling of the group was that those patients who had not asked for their test results did not want to know them:

[T]here was the feeling that ... maybe patients didn't want to know. Maybe once they know they are antibody positive, there is no going back, and if you don't know, then you can believe that you are negative .... It was a very new situation for us and we wanted to be sensitive to the patients because once you have told someone, you can't untell them.<sup>455</sup>

**1987**

**33.302** Professor Ludlam said that his approach of not insisting that patients knew their results changed around the end of 1986/beginning of 1987. As he explained:

[A]t that point ... the possibility of treatment with Zidovudine was being talked about. There was the possibility of prophylaxis against pneumocystis, the awful pentamidine inhalations. At that time ... one or two patients were starting to become clinically unwell, I assume because of the virus.

So a time came when I felt that it really was in the medical interests of the patients to tell them ....

[I]t was a balance and I thought it was becoming more in their interests, medical interests, to know.<sup>456</sup>

**33.303** He began asking patients to come in and see him. He could not recall how strongly he would have put it or how insistent he might have been, but he said that he would have made it very clear that he thought there were good reasons for patients to know their status and that he would like to tell them. He told the Inquiry that he either wrote to them or someone would ring them up and ask them to come in to the clinic.<sup>457</sup>

**Mark**

**Sister Billie Reynolds' evidence**

**33.304** Ms Billie Reynolds worked in nursing posts at the Edinburgh Haemophilia Centre beginning in June 1986. She provided an affidavit in which she challenged some of Professor Ludlam's recollections.<sup>458</sup> With regard to the patient given the pseudonym 'Mark' not finding out his diagnosis with HIV until January 1991, her impression was that Professor Ludlam 'could not face telling Mark his results'. She suggested that this reluctance stemmed from an earlier incident, when Professor Ludlam had given a positive test result to a patient of similar age in about 1986 and it had gone very badly.<sup>459</sup> Initially, she confused Mark with the patient concerned. Her account of events was disputed by Professor Ludlam in a statement provided by him to the Inquiry.<sup>460</sup>

**Professor Ludlam's evidence**

**33.305** Professor Ludlam said that he repeatedly tried to tell Mark the results of his HIV tests and that Mark repeatedly told him that he did not want to know them.

<sup>460</sup> Observations on Affidavit of Billie Reynolds dated 29 November 2011 by Professor Christopher Ludlam [PEN.018.1430]

**33.306** Professor Ludlam said that to begin with he was hesitant to let Mark know of his results because of ‘a number of social reasons’ but felt that a time came when it was important for him to know. He told the Inquiry that he arranged to see Mark sometime in 1986 (he could not recall the date) and said that he had been ‘quite taken aback’ because Mark was ‘quite categorical’ that he did not want to know his results. Professor Ludlam said that he was ‘a bit thrown’ by Mark’s reaction because he had not experienced a patient so determined that he did not want to be told. Professor Ludlam told the Inquiry that he informed Mark that he was telling everyone that they had to be very careful with blood spillages and sex. He was concerned that Mark might sustain injury in consequence of his manual employment.<sup>461</sup> Professor Ludlam explained:

We tried on at least two further occasions to convey this information to him. One was to potentially visit him at home and the other was when he came up to the clinic and he saw one of our very able young doctors and she tried to persuade him, very strongly – this would be about 1988 or 1989 ....

So there were several occasions when we tried very explicitly to explain to him and he adamantly didn’t want to know. And this wasn’t talking about iron levels; this was talking about HTLV-III and AIDS.<sup>462</sup>

**33.307** Professor Ludlam referred to a note from medical records which he thought was dated 13 November 1986:

There is the sheet that was in my private notes, if I can put it that way, that was from 1986 ....

This was a record of my seeing Mark in 1986, wanting to tell him about his result and he not being keen to know – or didn’t want to know the answer. I made a note of that and the advice that I gave to him and I felt it inappropriate to put it in his case notes for some of the reasons we talked about earlier, and I had a confidential file in my room, locked up, in which I kept that information. That information has now been returned to his principal case notes.<sup>463</sup>

### *Glasgow*

**33.308** Subsequent to the original Gallo test series, the local virologist, Dr Follett at Ruchill Hospital, set up a specialist laboratory and thereafter testing of west of Scotland patients was carried out there. Professor Forbes told the Inquiry that he arranged for Dr Follett to confirm the 12 original positive test results. He said that he wanted to confirm the initial results using a slightly different test but that the 12 patients who had already tested positive were informed of their primary test results before confirmatory testing by Dr Follett.<sup>464</sup>

**33.309** Professor Lowe told the Inquiry that it took some months for Dr Follett to get HIV tests up and running in his laboratory. He said that Professor Forbes and Dr Follett were both concerned about the specificity of the early tests: there were lots of false positives and false negatives. Given the increasing concern about the implications of a positive result, they wanted the test to be as accurate as possible. He said that Dr Follett took great care when setting up the test.<sup>465</sup>

<sup>462</sup> Ibid page 103

<sup>463</sup> Ibid page 104

<sup>464</sup> Professor Forbes – Day 33, page 133

<sup>465</sup> Professor Lowe – Day 40, page 47

**33.310** Professor Lowe thought that Dr Follett probably carried out HIV tests over the summer of 1985 but he could not be more specific about the date.<sup>466</sup> He recalled that, when patients attended the clinic centre in early 1985, after the 'update letter' but before local testing was available, a lot of time was spent talking to patients about AIDS and telling them that it was hoped that testing would be available in the near future. It was at this time that Dr Wilkie began counselling patients about the significance of HIV testing.<sup>467</sup>

**33.311** Dr Wilkie and her colleagues reported on the research exercise in a paper entitled 'Daily living problems of people with haemophilia and HIV infection: implications for counselling' which was published in 1990.<sup>468</sup> According to the paper patients were told, by letter, at the beginning of 1986 of the forthcoming study and that they would be invited to participate. This date, like many relating to the Glasgow exercise, is problematic. It appears that it may depend on the formal project start date rather than the actual date of the work. However, by way of background the paper stated:

Before the start of the project patients came to the haemophilia clinic at six-monthly intervals for review of their condition and received information about, and were tested for, HIV infection. In addition, many of them had obtained information about AIDS from the news-sheets from The Haemophilia Society, from television and from the press, and had read *AIDS and the Blood* (Jones, 1985) recommended by The Haemophilia Society.<sup>469</sup>

**33.312** Professor Lowe said that he was involved in seeing some of the patients who came for the appointments that had been arranged in the January 1985 letter. When asked what he told the patients he saw during these appointments, Professor Lowe explained that he would go through the letter and discuss the precautions to be taken by patients as this was considered a priority. He would then explain that Professor Forbes was arranging for HIV testing to be performed at the regional virus laboratory and that it was hoped that testing would be in place during 1985. He would tell them that, before such testing was performed, it was important that they had more information about the implications of testing and of both positive and negative test results. Patients would then be seen by Dr Wilkie. Professor Lowe said that blood would not be taken at that time and that he would never have taken a blood sample for HIV testing until the patient had been through the counselling process.<sup>470</sup>

**33.313** Professor Lowe did not know whether he saw any of the patients who had tested positive on the Gallo tests. He said that he never knew the names of those patients.<sup>471</sup> The appointments arranged in January were to discuss the risks, to emphasise the precautions to be taken, to talk about heat treatment and to explain that it was hoped that blood samples would be taken and tested in the future. By the time testing was ready to be carried out by Dr Follett, Professor Lowe considered that the patients had been 'pretty intensively educated and counselled' about HIV testing.<sup>472</sup> It is difficult, however, to imagine a situation in which Professor Lowe could have had such a conversation with a patient who had previously been told that he was HTLV-III positive on the Gallo test without that fact becoming apparent.

<sup>470</sup> Professor Lowe – Day 40, pages 44–46

<sup>471</sup> Ibid page 46

<sup>472</sup> Ibid page 48

**33.314** In April 1985 a further letter was sent to patients.<sup>473</sup> This was similar to the January 1985 letter but with some updating.<sup>474</sup> The April letter also enclosed Dr Peter Jones' booklet 'AIDS and the Blood' mentioned by Dr Wilkie in her article.<sup>475</sup> The letter and enclosed booklet were sent to all patients who were registered at the haemophilia centre at the time.<sup>476</sup>

**33.315** Professor Lowe told the Inquiry that, from that point, when patients attended the clinic and before any blood samples were taken for testing he would ask them if they had read the January letter, the April letter and the booklet.<sup>477</sup> Professor Lowe said he made sure that all the patients that he saw at the clinic at which time blood was taken were fully informed about HIV testing and its implications.<sup>478</sup>

**33.316** Professor Lowe thought that the great majority of the patients registered at the centre had been tested by Dr Follett over the summer of 1985 and certainly by October 1985.<sup>479</sup>

**33.317** He said that the results went to Professor Forbes and that about a dozen patients tested positive. Professor Lowe recalled Professor Forbes saying that when it came to telling patients results of positive tests they should make 'special arrangements'. Professor Forbes wanted one of the consultants (Professor Lowe or himself) to spend 'a good amount of time' with each patient and fully discuss the implications of their positive test result.<sup>480</sup> It is unclear how the twelve patients who tested positive in the bulk testing exercise described by Dr Froebel (paragraph 33.200) related to the twelve who tested positive in Dr Follett's series; however, it is reasonably clear that it was the patients identified by Dr Follett's study who had received pre-test counselling, and who had given informed consent, who were then informed of their results and counselled by Professor Forbes and Professor Lowe.

**33.318** Professor Lowe told the Inquiry that Professor Forbes' policy was that patients would be told at the next clinic review after a positive test result was discovered.<sup>481</sup> This usually took place within a few weeks of the blood sample being taken but would vary from patient to patient depending on when the results came back. No special arrangements were made for patients who tested negative. Professor Lowe said that, when a patient tested positive, he and Professor Forbes tried to make sure that they had time outwith the usual clinic routine where they could speak with the patient in private and have a long discussion. He said that often Dr Wilkie was present during these meetings and participated in the process of providing information and counselling to patients.<sup>482</sup>

**33.319** Professor Lowe thought that he would have passed positive results on to around half a dozen patients. In 1985 there were 12 HTLV-III antibody positive patients in the region and Professor Lowe thought that he and Professor Forbes had split the responsibility for communicating test results and counselling patients and had informed about half a

dozen each. He said that none of the patients that he informed expressed any surprise at all at the result.<sup>483</sup>

**33.320** Dr Wilkie told the Inquiry that often she was the person who told the patients that they had tested positive for the virus. She could not recall how many patients she personally delivered results to.<sup>484</sup> Professor Lowe challenged this evidence. He did not think that she would have had responsibility for informing patients of their test results herself but recalled that she would have been sitting with Professor Forbes or himself when the results were passed on.<sup>485</sup> Dr Wilkie said that she didn't have any recollection of sitting in with Professor Lowe; although she may have done so on some occasions, she said it was nearly always with Professor Forbes.<sup>486</sup>

**33.321** When asked to describe how a post-test interview would proceed, Dr Wilkie said that it would normally take place in the clinic rather than in the counselling room. She said that she or Professor Forbes would say that they were there to talk about the results of the HTLV-III tests. Like Professor Lowe, she recalled that patients generally appeared unsurprised at positive test results: usually the patient would say, 'I know doctor that I will be positive'. She said that they would then talk about the implications.<sup>487</sup>

**33.322** Professor Lowe told the Inquiry that when passing on positive test results to patients he would start by reviewing their knowledge about AIDS and HIV testing. He would make sure that they had received full counselling about the test and the implications of a positive or a negative result. He told the Inquiry that he would not have given anybody a positive test result without making sure that they had been through the process of pre-test counselling and fully understood the situation. He would ask the patients if they had been counselled and what information they had been given. He said that all of the patients that he gave positive results to told him that they had been counselled about the test.<sup>488</sup>

**33.323** Professor Lowe said that he told patients that AIDS was caused by a new virus and that a percentage of patients who had a positive antibody test would go on to develop AIDS but that it was not clear what percentage that would be or what the time frame for developing AIDS was. He said that he would reassure the patients that, at that time, the majority of patients found to have a positive antibody test were well and it was hoped that they would remain so. He said that he made sure that they had the current information about the risk of progression to both the milder and the more severe symptoms. He then gave them reading material and suggested that they return within a few days, having thought about the matter, with a list of any questions they wanted to ask.<sup>489</sup>

**33.324** He said that he told patients that he would want to see them more frequently thereafter – initially every couple of months – and that part of their routine examination would now involve monitoring them closely for signs and symptoms of progression to AIDS. They would also be reviewed by the local infectious diseases department at Ruchill Hospital.<sup>490</sup>

<sup>490</sup> Ibid page 63

## David

**33.325** As stated in paragraph 33.217 above, David was told by Professor Lowe that he had acquired HIV on 2 December 1985. The circumstances surrounding his diagnosis are detailed in paragraphs 5.173 to 5.178 of Chapter 5, *An Examination of the Effects of Infection with HIV on the Patients and their Families, Including Treatment*. David was unaware that his blood sample was being tested for HIV and he was very angry that he was tested for HIV without being told or being asked for his consent. When Professor Lowe told him his test result David thought that he spoke to him in a matter of fact way and wished to convey the news and move on.<sup>491</sup> Professor Lowe said that he had looked at David's medical records and that David had been seen by another doctor at the time that blood was taken for HIV testing.<sup>492</sup> He said that, although all of the testing that he performed himself had been preceded by counselling and discussion with the patient, he often saw patients who had been seen by another doctor at the clinic at the time that they had given a sample for testing.<sup>493</sup> In response to David's comments on the manner in which he was informed of his diagnosis with HIV, Professor Lowe stated that telling someone about their diagnosis at this time was very difficult due to the uncertainty at the time about the virus.<sup>494</sup>

## Discussion and conclusions

### *The threat of HIV transmission, haemophilia therapy in Scotland and the provision of information to patients*

#### Practice in Edinburgh and south east Scotland: discussion

**33.326** It is clear from the evidence presented to the Inquiry that Professor Ludlam's practice was that information was provided to his patients largely in response to questions posed by them and as, in his judgement, the occasion demanded it.<sup>495</sup> One could not conclude that any particular proportion of Edinburgh patients was given information until late 1984 at the earliest about the risks of transmission of HTLV-III by blood products. Professor Ludlam acknowledged that there was clearly a risk of the agent that caused AIDS entering the Scottish blood donor population and therefore potentially infecting his patients. From the epidemiology and from what was then known about the agent, however, it had seemed to him that the risk in Scotland was very small. He did not therefore take the initiative to alert patients explicitly to the risk and to any patients who may have asked about the risk he would have said that he thought it was small.<sup>496</sup> Advice was given occasionally and in response to questions or the need to explain the 'AIDS study' (discussed above at paragraphs 33.109 to 33.114) rather than universally. This was consistent with Professor Ludlam's view that there was no risk of transmission of HTLV-III with SNBTS products at the time.

**33.327** This appears to have been Professor Ludlam's position until the point in October 1984 when he received test results from Professor Tedder showing that some of his patients were HTLV-III antibody positive.<sup>497</sup>

<sup>497</sup> Professor Ludlam's note on long term safety monitoring for transfusion transmitted infections [PEN.012.0351] at 0354

### Practice at the Glasgow Royal Infirmary: discussion

**33.328** The evidence suggests that Professor Forbes would have discussed the threat of AIDS with his patients, whether in relation to product choice or in some other context. He said that he provided his assessment of the risk of AIDS but advised that they continue with their treatment.

**33.329** It is reasonably clear that there was not in force any structured protocol, or series of protocols, for the provision of information about the risks of transmission of HTLV-III by transfusion of blood products. While anxious to emphasise his own relative lack of seniority at the time, Professor Lowe, as an interested observer, was well placed to note practice and to comment on his own approach when dealing with the management of haemophilia patients.

**33.330** Clinical practice during review clinics provided an opportunity to deal with patients' questions, including questions about AIDS. The more significant question, however, relates to providing information about risk when discussing therapy. Professor Lowe's evidence is accepted: patients were told what was known about AIDS when the subject was raised, they were talked through the consequences of stopping treatment and told that, at the end of the day, they had to balance the risks and benefits of treatment. However, the provision of Haemophilia Society publications stressing the advice that patients should continue with concentrate therapy was also a significant element in the provision of information. Apart from 1985, and the fall-out from the discovery of antibodies to HTLV-III in Glasgow patients in 1984, the quantities of concentrate therapy dispensed reflected the practical emphasis on its continued use.

**33.331** It appears that at the GRI, as at the Haemophilia Centre in Edinburgh, during the initial phase of the epidemic AIDS was not discussed systematically with patients as a factor bearing on treatment.

### Practice at Yorkhill: discussion

**33.332** Professor Hann's predecessor at Yorkhill, Dr Michael Willoughby, left before the threat of AIDS in haemophilia patients had become a reality. Dr Willoughby's evidence was that he had no knowledge of the risk of transmission of serious viral disease. The evidence of the witness given the pseudonym 'Christine' is consistent with the impression given by Dr Willoughby: parents were not told by him that there was a risk of transmission of viral infection generally when being advised about treatment. This appears to the Inquiry to reflect the limited understanding of AIDS in 1981 and 1982. The critical period for present purposes began in 1983 when Professor Hann took up his post. While there were obvious differences among the witnesses relating to practice at Yorkhill, Professor Hann's evidence was clear and consistent, and provides a reliable basis for factual conclusions.

**33.333** Professor Hann joined Yorkhill as knowledge about the risk of transmission of a viral agent was first beginning to be disseminated, though his initial exposure to that information came, not in his new capacity as a haemophilia clinician, but in his previous post in London, where he had care of immuno-compromised patients. His position, on an objective view, was different from that of established haemophilia clinicians with a history of prescribing therapeutic products for haemophilia patients. It is therefore of some significance that his first strategic decision was to abandon Dr Willoughby's established practice of using commercial Factor VIII concentrates and adopt the exclusive

use of cryoprecipitate and SNBTS Factor VIII. As shown in Chapter 21, *Haemophilia Therapy – Use of Blood Products*, at paragraph 21.300 and in Figure 21.9, cryoprecipitate accounted for a very small proportion of total therapy. Until 1991, Professor Hann did not use commercial Factor VIII concentrate, with the exception of Dr Willoughby's residue in 1983, and small quantities in 1984 and 1986. Professor Hann's practice reflects consistent confidence in the Scottish product.

**33.334** The routine followed in dealing with patients or their parents during his period included discussions with patients about the relative benefits and risks of treatment options, so far as they were understood. It appears from the evidence as a whole that Professor Hann discussed HIV/AIDS to a greater extent than happened in Edinburgh and the GRI, although his advice, like that of Professors Ludlam and Forbes, was to continue with SNBTS therapy.

***The threat of HIV transmission, haemophilia therapy in Scotland and the provision of information to patients: conclusions***

**33.335** The evidence available to the Inquiry illustrates the independence of clinicians to adopt individual practices in providing information to their patients about the potential risks of transmission of viral infection generally, and of the putative AIDS agent specifically, in the period to 1984. It is also apparent that different views as to the nature and validity of the evidence of a viral aetiology were held by the clinicians at the different centres. There was then no relevant professional standard. As discussed in Chapter 32, *An Investigation into the Systems in Place for Informing Patients about the Risks – Ethical Context*, it would be 1988 before published guidance from the GMC<sup>498</sup> and the BMA<sup>499</sup> was available to the profession. That guidance was developed in the light of experience in the critical years 1983 to 1985. In that period, clinicians were free to develop their approaches on the basis of their individual perceptions of risk, and of the options available to them in treatment, given the fundamental need to treat patients' primary conditions.

**33.336** Professor Lever's observations (at paragraph 33.60 above) define, effectively and forcibly, the problem for clinicians. There was a need for caution in giving information and advice. Raising a fear of virus transmission would have caused distress and concern. If it should prove to have been unnecessary, that would be undesirable. People would 'not necessarily have been very understanding'<sup>500</sup> (a restrained judgment of the position) if it proved to have been a false alarm and, in the meantime, patients had died from lack of treatment for their haemophilia.

**33.337** Most senior clinicians would have been constrained by the knowledge that over the previous decade, as effective therapeutic concentrates had become available which had changed their patients' lives, they had prescribed concentrate therapy with confidence that, overall, the benefits conferred outweighed any disadvantages associated with their use. Professor Hann was an exception: he was new to haemophilia practice at this critical period, starting at Yorkhill in 1983, and had a quite different specialist background. In deciding his own approach to therapy, he proceeded quickly to near exclusive use of SNBTS products and, in becoming familiar with his patients, he was more active in initiating discussion of the options available in treating individual patients.

<sup>498</sup> *HIV Infection and AIDS: the Ethical Considerations*, General Medical Council, May 1988 [PEN.016.1165]

<sup>499</sup> British Medical Association, *Philosophy and Practice of Medical Ethics*, 1988, London, Chapter 4: 'Consent to Treatment' [PEN.018.0424]

<sup>500</sup> Professor Lever – Day 26, page 92

**33.338** The period when patients treated with SNBTS Factor VIII concentrate were most exposed to risk of transmission of HIV extended from 1983 to the beginning of 1985. That was the period when information about the risk of transmission and discussion with patients about product selection might, at least hypothetically, have been material to the course of treatment of their primary condition. Some patients have stated that they were not advised of the risk of contracting AIDS from treatment and there is patent concern that this reflected a failure on the part of clinicians to provide information to them.

**33.339** It is clear from the evidence that practice in relation to providing advice and information to patients about the risk of AIDS did vary. Professor Hann's practice at Yorkhill involved the most extensive discussion with patients and he appears to have adopted a proactive approach. Professor Ludlam's practice seems to have involved a more general level of discussion, and a more reactive approach, with information being imparted largely on a 'need to know' basis. His practice can be taken as an example of what happened to a greater, or lesser, extent at other centres. The overall picture that emerges from the evidence discussed in this chapter is that, generally, doctors in Scotland did not initiate discussions with patients about the risk of transmission of an AIDS agent because, for a significant part of the period, they thought that there was not a risk in Scotland at all and, towards the end of the period, they found it very difficult to assess the gravity of the risk that was beginning to be recognised. Nonetheless, if patients did enquire about the risk, the doctors would do their best to inform them, in the light of the then current state of knowledge about AIDS. Some clinicians at least also relied on the ready availability at clinics of publications from the Haemophilia Society.

**33.340** By the spring of 1983, Professor Ludlam had become convinced that there was a syndrome, AIDS, very possibly related to a transmissible agent like a virus, although it appeared to be largely a US phenomenon. He believed that his patients were not at risk from it because he used exclusively Scottish materials. In their case, any immune abnormality was attributed to antigen overload, occasioned by therapy as distinct from an infective agent. His anxiety, and the measures he implemented in consequence of it, to protect his patients from 'foreign' materials when outside Scotland provide eloquent evidence of his views at the time. Until the infectivity of a batch of SNBTS concentrate was discovered in the autumn of 1984, he took the view that his patients should not be exposed to commercial concentrates if that could be avoided.

**33.341** Professor Vivienne Nathanson talked about the uncertainties surrounding the risk of AIDS between 1982 and 1984. She said that all of these uncertainties made it extremely difficult for treating doctors to discuss the risks associated with their treatment because they were unable to categorise the level of that risk.<sup>501</sup> At the beginning of the period the level of uncertainty about the risk was such that it was legitimate for clinicians not to mention it to their patients.<sup>502</sup> The problem facing treating clinicians was that they did not have numerical data and therefore did not know the level of risk. The question at that time was, therefore, whether to wait for it to become clear from the statistics that the risk to patients was so common that they must be told, or to tell patients about the risk, regardless of the likelihood of their infection, because the consequences were so great.<sup>503</sup> She said that it became less acceptable not to warn patients as clinicians began to understand the risks and as it became clearer that the risks were higher than originally thought.

---

<sup>501</sup> Professor Nathanson – Day 37, pages 74–75

<sup>502</sup> Ibid page 77

<sup>503</sup> Ibid pages 79–80

**33.342** Professor Nathanson was not critical of doctors who did not initiate discussions about the risk of AIDS from concentrate therapy in the early 1980s. It is clear that by modern standards a doctor could be criticised for failing to mention a risk to a patient that a particular treatment carries. However in the early 1980s it was commonplace for doctors simply to take decisions for their patients without discussion with them, the so-called 'paternalistic' approach to practice. As the exact extent of the risk was then unknown, a significant number of doctors would not have initiated a discussion about the risk of contracting AIDS by continuing with factor therapy even though by 1984 it was clear that there was a risk of death.

**33.343** Until September 1984 (by which time it was generally accepted that HTLV-III was the agent of transmission of AIDS, and a high prevalence of the HIV virus in UK haemophilia patients had been found) there is no basis in the evidence for any criticism of any Scottish clinicians relating to their approaches to the provision of information and advice concerning the risks of AIDS associated with the continued use of therapeutic materials in the treatment of blood coagulation disorders.

**33.344** There were no specific ethical guidelines for this unprecedented situation. Practice in Edinburgh and Glasgow was tailored to patients' needs as perceived by the various clinicians. Professor Ludlam's provision of information on a reactive basis was, inevitably, a reflection of his personal approach to clinical practice as was Professor Forbes' approach. Relevant to all the clinicians involved was the fact that knowledge of AIDS was limited and, consequently, that there was little that they could tell patients about it with any confidence.

**33.345** The position towards the end of 1984, immediately before Scottish practitioners discovered the results of testing by Professor Tedder and Dr Gallo of samples from their patients, examined below, is that the risk of AIDS was not generally discussed. However, on the evidence of general practice prevailing at the time, particularly from Professor Nathanson, there is no basis for criticism of individual clinicians.

## **The testing of patients' blood samples**

### *Routine blood tests to 1984: discussion and conclusions*

**33.346** Monitoring of patients by blood tests was a routine component of haemophilia care throughout UK haemophilia centres from the 1970s. Dr Winter described the background to this practice. He noted that, shortly after the introduction of factor concentrates in the mid-1970s, it became apparent that nearly all regularly treated patients displayed biochemical abnormalities of liver function of a type that would be compatible with a form of viral hepatitis infection. From that time on, haemophilia clinicians regarded it as their responsibility to monitor their patients regularly for the presence of new viral infections.<sup>504</sup> It was absolutely routine to test haemophilia patients for viruses, whether directly or by means of surrogate indicators of disease, and, because it was seen as being a core part of patient care, it was not considered necessary for doctors to discuss it with patients.

**33.347** Routine testing such as described was an ordinary aspect of diagnosis and of management and did not give rise to controversy at the time. However, in 1983 and early 1984 studies were carried out in Edinburgh and Glasgow that became controversial later. They arose from the discovery, initially in the USA, that haemophilia patients had

---

<sup>504</sup> Dr Winter – Day 16, page 155

developed immune abnormalities which were similar to those found in AIDS patients and reported to be found in some asymptomatic homosexual men. It is appropriate to re-emphasise that, until the immunological studies, the evidence of practice gathered by the Inquiry shows that blood tests for a wide variety of pathogens and for monitoring biometric data were carried out on a routine basis without prior discussion with patients as necessary components of the management of their primary condition.

### *Immunological studies: discussion and conclusions*

**33.348** The evidence suggests that Professor Ludlam may have found it difficult to explain to patients about his immunological studies. Some of his patients may have known that he was carrying out such studies but there was no structured or systematic approach to providing relevant information relating to it, or for obtaining consent for the use of patients' blood. Some patients may have understood from their haematology request forms that their blood was being tested in the 'AIDS study'. However, no reliance could reasonably have been placed on the forms as a means of informing patients of that fact, or of the significance of the studies. Equally, it seems that, at the time and in the retrospective analysis Professor Ludlam required to undertake for this Inquiry, he did not fully appreciate the possible impact on them of the language he used. This is, perhaps, best illustrated by his labelling, in the climate of the time, his immunological investigation as the 'AIDS study'. That choice of words gave rise to a suspicion, harboured by few people, that he had been experimenting on his patients with the AIDS virus. It should be noted that Counsel representing the Patients, Relatives and the Haemophilia Society explicitly acknowledged that there was no factual basis for such a suspicion.<sup>505</sup> Furthermore, it is worth repeating at this juncture, that it is the view of this Inquiry that such a suspicion is without foundation.

**33.349** There was good reason in 1982–83 for Professor Ludlam and Professor Forbes to be concerned about whether their haemophilia patients had been exposed to the transmissible agent then increasingly thought to be responsible for AIDS. The topic had been explored in the United States. The possibility of 'antigen overload' as an explanation of immunological abnormalities had been postulated as an alternative to viral infection. By the spring of 1983 the incidence of similar immune abnormalities in AIDS patients, some asymptomatic homosexual men and some asymptomatic haemophilia patients, was puzzling. It was a subject appropriately demanding investigation.

**33.350** If Professor Ludlam had contemplated the range of possible reactions to this work on the part of patients, he would have been well advised, as he came to recognise, to have devised an alternative shorthand to 'AIDS study' to describe it. Much of the reasoning and explanations tendered in oral and written evidence would not then have been required. For example, the discussion of what patients 'might have understood' from a label on a form accompanying a sample appeared to be unhelpful at the time of the Oral Hearings and has remained so. In the end, discussion of the description, and of possible inferences that might be drawn from the use of the title, provided no help in characterising what was done and in developing views on the appropriateness of that course of action.

**33.351** Several facts are established in relation to Edinburgh:

- Professor Ludlam was aware from international and UK sources that some clinically well haemophilia patients were developing immune abnormalities.

---

<sup>505</sup> Day 39, pages 11–12

- He knew that the pattern of these abnormalities, though less marked in haemophilia patients, bore similarities to those found in some apparently well homosexual men and in AIDS patients.
- The cause was unclear and it was also unclear whether the condition was progressive. It might have been a previously unreported side-effect of therapy or of haemophilia itself.
- On the other hand, the changes might have been related to the prevalence of a blood-borne virus possibly leading to AIDS.
- The condition in his patients could be investigated by the addition to routine haematological lymphocyte counts of a more specific count of CD4 and CD8 lymphocytes, and an assessment of their relative proportions in the patient's blood, using the same blood as taken for standard haematology.
- Professor Ludlam made an arrangement with Dr Steel to have that test carried out on selected samples from patients with severe and moderate haemophilia who had received a lot of concentrate.
- Patients were not told routinely that the study was carried out or that their blood was used, and their consent was not obtained in advance.
- While some patients may have been told, or found out, it could not be concluded on the evidence that the study was known generally or that all patients involved knew of the study or that their blood was used in it.

**33.352** However the study was in the best interest of patients. Finding out whether there was a pattern of immune abnormalities and, if so, its nature and extent could not but have been relevant to patient care whether it was caused by, or associated with, the selection and use of therapeutic products, or involved an agent of transmission of viral infection. The results of the study might be of particular importance in deciding on future therapy. The progressive development of immune abnormalities in patients receiving factor concentrates was a matter of legitimate concern in itself. At this stage, in 1982–83, the common perception in Scotland was that SNBTS Factor products were safe from AIDS and, to the extent it was understood, from an infectious agent associated with AIDS. That was an illusion, as events were soon to prove, but it was deeply embedded in the preference for the domestic product over imported products, especially those imported from the USA.

**33.353** Attempting to differentiate the effects of 'antigen overload' from infection with an AIDS agent would also have been a legitimate concern. That was what lay behind Dr Louis Aledort's studies in America that prompted Professor Ludlam to carry out his own investigations. On any view, the study and the findings potentially had real significance in the context of patient management. If, without virus infection, immune abnormalities developed through the use of concentrates, that would have been important.

**33.354** The question of whether patients should have been informed and whether their consent should have been obtained in advance of the immune studies is more difficult. It cannot be answered by reference to what was found: that was, of necessity, unknown when the material decisions were taken (or, more probably, not taken, since the test was clearly viewed as a simple extension of routine practice). It cannot take into account the emergence of HTLV-III positivity in Scottish patients: that still lay in the future. Similarly,

many of the problems associated with HTLV-III/HIV testing that were to emerge in and after 1985, such as problems relating to employment, to travel and to insurance, were unknown in Scotland in 1983.

**33.355** The matter was taken up with Professor Nathanson, who discussed the distinction between 'monitoring of patients' and 'research'. She said that, in essence, research involves testing a theory about, for example, a causation or the result of a treatment.<sup>506</sup> She said that there is often a very fine line between medical research and treatment. She referred to the old version of the Declaration of Helsinki which talked about 'therapeutic' and 'non-therapeutic' research. Although the phrase 'therapeutic research' is not used today, it was at that time and Professor Nathanson thought that it lay on the fine line between 'monitoring of patients' and 'research' as such.

**33.356** There are times when what a doctor is doing is not part of established therapy (including established protocols for continuing testing or routine tests) but is an aspect of the way in which the doctor is treating that patient, either finding out more information about the patient or seeking a better way to treat their condition. This has always been an area where it is difficult to say whether what the doctor is doing is better characterised as research or as treatment because some such actions straddle that line. Professor Nathanson said that she would characterise the immune function studies carried out by Professor Ludlam between 1983 and 1985 as being 'exactly on this borderline'.<sup>507</sup>

**33.357** When asked whether it would be fair to suggest that something might start out as long-term safety monitoring of patients and metamorphose into what might objectively be regarded as research, Professor Nathanson said:

I think that's absolutely the case. I think this is clearly the issue when you start off with work that is on this borderline, that you start off intending to simply monitor that you are getting the treatment right, that the patient's blood tests are going in the right direction or you are not seeing anything unexpected. You find something unexpected and it morphs into something that is different, and that's a very great difficulty and it's particularly difficult to then stop what you are doing and to redesign the whole thing and to say, 'We will now make this into a formal research protocol.' And I think that that's why, in times when the ethics approval for research was rather less rigid than it is today, that much of this happened. It didn't start off with malign intention, it just metamorphosed in exactly that way.<sup>508</sup>

**33.358** So far as the immunological studies are concerned, classification remains difficult. Viewed as a research project, the testing of those severely and moderately affected haemophilia patients who attended Professor Ludlam's clinic for treatment or review during the period of the AIDS study was not based on the random selection of patients from a wider population. Nor was there a defined research protocol for the study. On the other hand, routine monitoring might have been expected to require that the lymphocyte study should include all patients rather than only those who attended for treatment or review. As already commented, the results might also have been expected to be noted in patients' medical records.

---

<sup>506</sup> This definition of 'research' has to be understood in the context of the discussion of the immune studies: it would now be regarded as out of date more generally. 'Blue Sky' research would not be encompassed by the definition.

<sup>507</sup> Professor Nathanson – Day 37, pages 160–162

<sup>508</sup> Ibid page 166

**33.359** While lacking such a formal structure, there are indications that the intent of the projects was research in a wider sense than the investigation of the individual patient's condition. It might not have met Professor Nathanson's definition of the essence of research. The 'theory under investigation' was, at best, the hypothesis that immune abnormalities found in haemophilia patients had an association with antigen overload rather than a ubiquitous viral agent. It was designed to obtain information, to find out whether there were immune abnormalities in the Edinburgh Haemophilia Centre patients generally and was therefore not focused on individual patient management. It might have been more consistent with the 'monitoring' of patients (as Professor Ludlam described it) rather than a form of unstructured research if all patients had been tested rather than a selection only. The immune studies resulted in published papers rather than in changes in the prescription of therapy. So far as the individual patients were concerned, Professor Ludlam clearly did not know what to do with the information gathered. He did not tell the patients; he could not interpret the results for them. The implications for management of the patients had not been considered at that time: apparently that had not been part of the plan.

**33.360** It is not clear where these exercises would lie relative to the fine line between 'therapeutic' and 'non-therapeutic' research sketched out by Professor Nathanson. They were exploratory exercises aimed at finding out what, if anything, was happening to patients receiving blood product therapy. Professor Nathanson thought that the immune studies lay on the borderline and that is probably where they should be left. Her comment relating to studies that 'morph' into research in the fullest sense of the term is no doubt accurate in the abstract but it is not accurate in relation to the immunological studies in Edinburgh and Glasgow: there is no evidence that the studies changed in content, purpose or direction, which the word 'metamorphose' would suggest. So far as the evidence shows, what changed over time was the perception of the studies which came to reflect ethical rules developed after the work was carried out and reported.

**33.361** In Glasgow and in Edinburgh, the immunological studies are probably best characterised as a preliminary enquiry. They were aimed at finding out whether the patients' lymphocyte 'scores' suggested that something was happening to their immune systems that might be related to therapy. Due to their unstructured, preliminary character, a full research programme following upon them would have been required if reliance was to be based upon their conclusions in instructing any changes in the approach to therapy. Professor Forbes characterised the Glasgow study as an investigation aimed at finding out whether there was any evidence of altered immunological status in patients who had received multiple transfusions with various products. He described the paper as 'very much a preliminary paper'. His team did not know where the results might lead them.

**33.362** If there had been at the time a generally recognised ethical rule that patients should be informed of all research in which they were involved through the use of blood samples, and that their consent should be obtained before use was made of their samples, the conduct of the 'AIDS study', as it was carried out, would have infringed that rule. The Glasgow study, since consent was obtained, would not have done so.

**33.363** However, as indicated earlier in this chapter, and in Chapter 32, *An Investigation into the Systems in Place for Informing Patients about the Risks – Ethical Context*, on the evidence available, from Professor Nathanson in particular so far as general theory is concerned, and from Dr Winter and others from the clinician's point of view, there was not a fixed rule before 1988 that would have required that the patient be informed or that the

patient should consent to the immunological tests. There was no rule that took the decision whether to seek consent for immunological studies out of the clinician's discretion.

**33.364** Professor Nathanson said that even at that time she would have encouraged Professor Ludlam to consider the work as research and follow the research protocols simply because of the benefits that would have brought.<sup>509</sup> However, that plainly fell short of criticism that what had been done breached any ethical rule in force at the time.

**33.365** Professor Nathanson's evidence is accepted. The immune studies were not simply the reflection of the insatiable curiosity of academic doctors confronted with an interesting project and an irresistible urge to research it. Professor Ludlam and Professor Forbes had a legitimate clinical interest in discovering whether concentrate therapy had an impact on patients' immune function. As events were to develop after the AIDS period, the 'purity' of intermediate factor products became an important issue for the SNBTS. In due course, pressure from patients and clinicians grew for the development of 'purer' concentrates, with lower levels of protein impurities than had generally been found in SNBTS intermediate purity products, and in particular SNBTS Factor VIII. A study that focused on the consequences for patients' immune systems of therapy with products of intermediate purity, with a clearly specified aim and supported by a research protocol, could readily have been classified in 1982 as 'therapeutic' research ancillary to patient management and treatment.

**33.366** The immunological studies carried out in Glasgow were not a direct parallel of those conducted in Edinburgh, even though the objective was the same. The study in Glasgow was prompted by the same intelligence that influenced Professor Ludlam and was aimed at finding out whether there was evidence that patients who had received multiple transfusions had developed immune abnormalities. On Professor Forbes' evidence fresh blood samples were required specifically for the study and that necessitated discussion with patients.

**33.367** As observed earlier, Professor Forbes' account of the procedure adopted was imprecise. The impression he gave was of a fairly informal approach to obtaining consent with little information about the purpose of the study imparted to patients. Dr Froebel's published report of the study does not indicate whether the patients gave their consent; it refers to the patients having been selected because of their treatment regime in the recent past.<sup>510</sup> In the absence of any contrary evidence, it is appropriate to proceed on the basis that the patients were asked to participate in the study and gave their consent, albeit informally and with little specification of the purpose and significance of the study.

**33.368** Like Professor Ludlam, Professor Forbes obtained results but did not know what to do with them in the context of patient management. He did not go back to the patients with their results because he did not know the implications of the findings. There was no follow-up to the results, so far as the specific patients were concerned. In the event, what he actually told his patients and how well informed they were about his immunological investigations are open questions. His approach can properly be described as paternalistic, in the sense previously defined, leaving patients with the impression that he was doing something for their own good but avoiding overloading them with information about it.

---

<sup>509</sup> Ibid page 162

<sup>510</sup> Froebel et al, 'Immunological abnormalities in haemophilia: are they caused by American factor VIII concentrate?', *British Medical Journal*, 1983; 287 [LIT.001.0215]

**33.369** The 'skin tests' carried out in Edinburgh and Glasgow illustrate that clinicians did draw a line and seek ethical approval where they perceived that the work involved amounted to research. The investigation for the 'skin tests' was invasive: it was intended to test immune response by causing physical changes in the patient's skin.

**33.370** Professor Ludlam viewed his skin test programme in 1984 as a research project requiring ethical approval. He took a different view of the immunological studies he carried out on stored samples. They did not require fresh blood samples to be taken, and were, in that sense, not invasive. That was a matter of judgment on which he was entitled to take a view at the time. There was little difference between them: they had the same objective, involved patients' immune functions and they both provided general information. The more invasive exercise received ethical consent when Professor Ludlam sought it. It is very difficult to see anything of substance turning on the failure to seek ethical consent for the immunological studies.

**33.371** In retrospect, aspects of the conceptualisation and implementation of the 'AIDS study' could have been handled better, but it is not possible to say that there was any breach of any ethical rule prevalent or recognised at the time the studies were carried out.

#### *Publication of patients' information: discussion and conclusions*

**33.372** Professor Nathanson explained that in contemporary practice where data is extracted from the files of a limited number of patients, where the researchers know the identity of the research subjects and especially if they comprise a small, defined and potentially identifiable group, the researcher is obliged to obtain the consent of the patient(s) to the inclusion of their data in the research. The GMC considers such cases in its supplementary guidance on research ethics, which makes it clear that identifiable data requires either patient consent or, where that cannot be obtained, separate independent permission to use such data.<sup>511</sup>

**33.373** She said that the main thing that most patients worry about in research publications is whether they can be identified from the description in the article. Today in almost all publications, patients are given a guarantee that the information will be aggregated or presented in such a way that they cannot be identified from it. This fits with the valid consent model and patient-centred practice. Patients are given the choice of either being in the research exercise or not. Another key component of research ethics is that a doctor should also make sure that patients understand that refusal to be part of the research will not change their access to healthcare.<sup>512</sup>

**33.374** Professor Nathanson also discussed 'anonymisation' and 'pseudonymisation'. Anonymisation is the practice of making sure that whatever is done with the information used in the research, such as actual files about individual patients, is treated in such a way that all identifiers are removed. Pseudonymisation involves the use of false personal information to conceal an identity. With anonymisation doctors have to be very careful that they are not presenting information which, even though they have removed the patient's name and date of birth, has enough detail to allow the patient to be identified. Nowadays the biggest research studies use fully anonymised data. Often they use aggregated data, which might look at information extracted from, for example, the population of 5 million in Scotland.<sup>513</sup>

---

<sup>511</sup> Professor Nathanson's first report to the Inquiry [PEN.012.0330] at 0340

<sup>512</sup> Professor Nathanson – Day 37, page 131

<sup>513</sup> Professor Nathanson – Day 37, pages 131–133; Professor Nathanson's first report to the Inquiry [PEN.012.0330] at 0340

**33.375** She said that the fact that the results were published made very little difference to any ethical concerns around the immune studies. She recognised that the use of patient information in medical journals, anonymised but without formal consent to inclusion in a published study, was fairly common in the 1980s. The important point about publication at that time was that it required consent if there was any likelihood of individuals being identified.<sup>514</sup> All three of the articles mentioned were fully anonymised.

**33.376** The publication in *The Lancet* of the results of the immunological studies from Edinburgh and Glasgow did not infringe any ethical rule recognised in 1983. On Professor Nathanson's evidence, they would not infringe current rules. The data were fully anonymised and there was no likelihood of individuals being identified. As Professor Nathanson said in this context, publication made very little difference in this case. It does not affect the legitimacy of either of the studies.

**33.377** While the feelings of the patients on finding out that they were part of such studies without their knowledge are easily understandable, in the result there was no breach of any ethical rule or principle associated with the publication of the results of the immune studies.

### *Testing for anti-HTLV-III: discussion and conclusions*

#### Glasgow

**33.378** The evidence of the timing of events in Glasgow is confused and in some respects contradictory. Dr Froebel's evidence is accepted and is generally to be preferred to competing accounts. It relates most naturally to the reports, from Montagnier in France and Gallo in the US, claiming that a virus had been isolated from patients with AIDS and indicating that both laboratories were working on an antibody (ELISA) assay, a blood test that would show exposure to the virus (though attributing the date of spring 1984 to each, as Dr Froebel did, was incorrect). Her narrative of the assembly of samples and their dispatch to Dr Gallo has circumstantial detail that supports its accuracy. She cannot have written to Professor Montagnier and Dr Gallo before 4 May 1984 when *Science* published the articles on Gallo's research. The samples that were tested were recorded in the subsequent paper published in *The Lancet* as having been taken between December 1983 and July 1984. The samples therefore cannot have been sent prior to July 1984. The HTLV-III antibody testing of the Glasgow samples in Dr Gallo's laboratory must have been carried out thereafter.

**33.379** The only evidence suggesting that Professor Forbes had knowledge of HTLV-III antibody test results for some patients before the report of the bulk shipment of named samples to Dr Gallo, was provided by Dr Wilkie, and concerned the kits. She made no reference to the Gallo tests. Whilst trying her best to assist the Inquiry she had, as she acknowledged, difficulty in recollecting certain matters including dates. In relation to the test kits, she said that she and Professor Forbes conversed on this matter once and then never again. Many matters referred to by her in relation to the kits would fit equally well in the context of the Gallo tests. Her description of Professor Forbes' agitation would fit his likely state on discovering from the Gallo test results that 16% of his patients had tested positive. Like the putative kits described by her, the Gallo test originated in the USA and was unlicensed. On the basis of either the Gallo results or the kit results, Professor Forbes would be concerned to find out what his patients knew about HTLV-III, whether they

---

<sup>514</sup> Professor Nathanson – Day 37, pages 162–163

thought they might be affected and whether they would like to be tested for the virus. Neither Professor Lowe nor Dr Froebel referred to any test kits, and Dr Froebel stated that she expected the Gallo tests to be negative and was shocked by the positive results. She and Professor Forbes were collaborating and it is difficult to think of any reason why he would keep any pre-existing positive results from her. Furthermore, positive HTLV-III test results from patients at the GRI would, in all probability, have significance for the SNBTS and the PFC. Dr Wilkie described Professor Forbes as 'a very ethical man with far-reaching ideas'. Professor Lowe said he was 'an extremely open person who would spend hours with his patients, discussing all manner of things'. The weight of the evidence on this matter suggests that the first HTLV-III testing of GRI patients was by Dr Gallo.

**33.380** It appears likely that when those first test results came to hand they would have caused the agitation Dr Wilkie described and provided the incentive she needed to abandon her own lines of research and agree to assist Professor Forbes. Her evidence that the reason Professor Forbes had contacted her was agitation about the test results and that had prompted him to ask for her help, is accepted.

**33.381** The Inquiry endeavoured to ascertain the likely date upon which the Gallo test results first became available at the GRI. On 29 October 1984, Dr Froebel wrote to Dr Perry that, after checking records, she and her colleagues now thought that seropositivity for HTLV-III was strongly associated with the patients having received commercial concentrate mostly before 1981. Dr Gallo's results were clearly available before 29 October 1984. On 29 November 1984, a meeting of haemophilia directors and SNBTS representatives was held. Paragraph 4 of the minutes notes:

Dr Forbes described the findings relating to HTLV-III antibody sero-conversion in a comparative study of haemophilia patients in Glasgow and Denmark. This study would shortly be published in the *Lancet*.<sup>515</sup>

**33.382** The exact date that Professor Forbes received the results from the USA is not known but it must have been some time before this meeting since in the interval Dr Melbye became involved in the joint exercise with Glasgow, research was completed, and the joint paper was prepared, submitted for publication, reviewed and finally approved for publication all before December 1984. The article was published in *The Lancet* of 22/29 December 1984.<sup>516</sup> It contains data on a patient who died in late October, but that could have been added in the review process. Professor Lowe is recorded as one of the authors of the article. He said that he was not involved in collecting blood samples from patients or sending them for HTLV-III testing.<sup>517</sup> His involvement was limited to a critical review of the draft paper, probably around about September or October 1984.<sup>518</sup>

**33.383** On the evidence as a whole, it seems highly likely that Professor Forbes had the results of Dr Gallo's tests by late summer or early autumn 1984, in time for the work leading to the article in *The Lancet*. He may have had them by August or September. A date in October is less likely, notwithstanding the reference to the October death, given the spread of authors between Scotland, Denmark and United States, and the confirmatory tests referred to in the article.

## Edinburgh

**33.384** The timing of some events in Edinburgh is also open to doubt. On Professor Tedder's evidence, Professor Ludlam made an initial approach in August 1984. That would have been before the publication in the Cheingsong-Popov article of the results of the Tedder/Weiss research project in September. Since the approach was made on the basis of personal connection that is not at all unlikely, but at the time of the initial approach, on Professor Ludlam's evidence, Professor Tedder was already inundated with requests from various sources for HTLV-III testing, a situation more likely to relate to publication in September. The critical issue is related to the submission of the first particular group of samples that resulted in the positive diagnosis of infection. That places the event in October 1984 and for practical purposes, on the evidence as a whole, Professor Ludlam's timing is accepted.

## The ethical considerations

**33.385** From the accounts of the way in which events unfolded, already dealt with at length, it is clear that in both Edinburgh and Glasgow, the initial samples of sera for testing were selected from store and submitted without prior consent of the patients, though the samples were identified as belonging to identified individuals. The wide context is relevant.

**33.386** In Professor Nathanson's opinion, the use of stored blood or tissue samples for research would have been contrary to the spirit of the Declaration of Helsinki if consent had not been obtained. However, if doctors were not using the information for research but rather as a part of the continuing monitoring of the patient that would have been legitimate. She noted that there is 'a very fine line' between the two uses of samples.<sup>519</sup> This appears to be the difficult line between 'therapeutic' and 'non-therapeutic' research already discussed.

**33.387** In her view it was clear that the spirit of the Declaration of Helsinki dictated that, if doctors had been in any doubt, they should have erred on the side of thinking that there was a need for a research protocol and gone through the relevant processes.

**33.388** However, she said that although conducting research without consent might be contrary to the spirit of the Declaration, particularly as that is understood today, in practice it did occur quite widely in the early 1980s. Doctors often regarded what might now be considered to be research as part of continuing care, or a 'check and balance' on the quality of care a patient received. Although Professor Nathanson said that she would be critical of a doctor who had used stored samples without the patient's consent, she recognised that this was, in fact, common practice in the 1980s. As she put it: 'I would say it was not ... the gold standard but it was a common fault and it was commonly done'.<sup>520</sup>

**33.389** Throughout the United Kingdom, and across Scotland, there were haemophilia clinicians who used stored samples for testing without patient consent in the course of day-to-day monitoring of patients' progression.<sup>521</sup>

**33.390** Having regard to the discussions that led to the 1988 GMC guidance, and notwithstanding Professor Nathanson's opinion of what the spirit of the Declaration of

---

<sup>519</sup> Professor Nathanson – Day 37, pages 136–137

<sup>520</sup> Ibid pages 137–138

<sup>521</sup> Dr Tait – Day 14, page 65

Helsinki required, it is not possible to hold that there was an accepted or established rule of ethical practice that required patient consent for the submission of stored samples for testing in all circumstances in 1984. There are, however, substantial questions relating to the particular case of conducting HTLV-III/HIV studies on stored, and named, samples without consent of the patients involved. AIDS was already understood as a devastating disease in 1984 and the possibility of infection with an agent that might lead to the development of an AIDS disease, however remote, was a matter of real concern to patients and their families.

### *Communication of the results of HTLV-III testing: discussion and conclusions*

#### **Edinburgh**

**33.391** So far as concerns intimation to patients, the response to the findings was slow. After the initial flurry of telephone calls and memoranda at the end of October, nothing had been resolved in Edinburgh by the date of the meeting of Scottish Haemophilia Directors, SNBTS representatives and SHHD personnel convened on 29 November 1984. The position in Glasgow was the same. The meeting of the Haemophilia Reference Centre Directors at the BPL, Elstree, on 10 December 1984 left matters concerning whether and how patients with positive results should be informed in the hands of individual Haemophilia Directors with no real guidance on how to handle the situation. The approach in Edinburgh changed to crisis management with the threat of publication in *The Yorkshire Post* received by Professor Ludlam on 11 December.

**33.392** At the present time, when protocols for managing relations with the media are rather better developed, the course adopted by Professor Ludlam may seem inapposite, even unwise. It should, however, be considered in the light of the circumstances then prevailing. The day after the long and difficult meeting on 10 December, he was contacted by a *Yorkshire Post* reporter who informed him that he knew about the Edinburgh seroconversions, wanted to publish that information and would like to meet him. The following day they met and Professor Ludlam begged the reporter not to publish, explaining that this was no way for the patients to receive such news. Negotiating hard, he managed to extract one week's grace. Later that same day he wrote the invitations to the meeting, thinking such a gathering would be the quickest, most open way to start to inform all the patients. Professor Ludlam said in his evidence that had *The Yorkshire Post* not intervened, he would have found a different way of advising the patients. In retrospect, and as he acknowledged, it is plain that a public meeting was not the best way either to disseminate important personal information or to provide sensitive advice. However, the evidence does not disclose any objection to the course of action that he took, and it was reported to Scottish Office officials at the time.

**33.393** On the evidence gathered by the Inquiry it is clear that Edinburgh-registered patients and their families were invited to the meeting of 19 December 1984. Professor Ludlam concluded that some of those attending must have come from Glasgow as he did not recognise them. However, he also stated that he would have sent out invitations to the east coast haemophilia centres at Aberdeen and Inverness. The patients he did not recognise could have come from the other east coast centres. Unfortunately, the evidence in relation to Glasgow produces a less clear picture than that relating to Edinburgh, in part due to Professor Forbes' difficulties with his memory. Professor Ludlam believed that Professor Forbes had sent invitations to the meeting to his GRI patients. *The Yorkshire Post*, in its near contemporaneous account, stated that news of the positive testing was

broken 'to haemophiliacs from Edinburgh and Glasgow'. Information for that article came from Professor Ludlam and that account would be consistent with his belief at the time. Dr Bell's memorandum, dated 12 December 1984, suggested that 'the haemophilia consultants' were going to call a meeting of haemophilia patients. On the other hand, Professor Forbes (who chaired the meeting) had no recollection of any Glasgow patients attending. Neither Professor Hann nor Dr Pettigrew appears to have sent out invitations. On balance, it seems likely that for some reason west of Scotland patients were not invited to the Edinburgh meeting and did not attend it.

**33.394** After the meeting different courses of action were followed in Edinburgh and Glasgow and, as appears from the letter sent to patients by Professor Forbes and Professor Lowe on 8 January 1985, communication with Glasgow patients did not include any reference to the meeting. The tone of the letter was 'prospective': it proposed a fresh course of action that had no reference to an earlier meeting. It appears likely that Professor Forbes had already decided to pursue his own course by the time of the meeting and that he proceeded to implement his plan of action without reference to Professor Ludlam.

**33.395** The invitation to attend the meeting suggested something like a general information session. It was, unfortunately, ill-adapted to inform patients and their families that, among the recipients of the letter, there were individuals who were already known to have been infected with HTLV-III. Yet, on Professor Ludlam's evidence, one of the two objectives of the meeting was to inform those who attended that some patients were positive for the antibody. Patients would not have been prepared for information to that effect. The evidence of what transpired at the meeting has been set out fairly fully. It is not clear that specific information was given about the particular centres at which the 'Scottish' patients who had been infected were treated. Since Professor Ludlam had anticipated that Glasgow and west of Scotland patients would have been invited as well as those in other regions, the information was unhelpful and could have left patients in confusion about what they might be told at the meeting.

**33.396** For the reasons already discussed, the article published in *The Yorkshire Post* on 20 December 1984 cannot be treated as a wholly reliable account of what transpired at the meeting. In any event, it is not clear from its content what precise information was imparted to patients on that occasion. The article published in *The Edinburgh Evening News* on 21 December was brief and lacked specification of what had transpired at the meeting, commenting only that '[t]he situation was explained to haemophiliacs at a meeting with medical experts in Edinburgh this week'.<sup>522</sup>

**33.397** Plainly, the most reliable evidence in relation to the meeting is Witness A's note. It suggests, amongst other things, that practical information was imparted about how to avoid transmitting the virus together with additional information about HTLV-III and AIDS. From its terms, Professor Ludlam also seems to have indicated that he was prepared to inform his patients if they had the antibody to the virus. Mrs Brown believed he had communicated at the meeting that there was an infected group in Edinburgh, those present might be in that group and if they wanted to know if they were infected or not, they had to ask.

**33.398** The notes of Witness A and Geraldine Brown's evidence both suggest that at the meeting Professor Ludlam did communicate that he was offering to inform any of

---

<sup>522</sup> 'Plea to donors in AIDS alert', *The Edinburgh Evening News*, 21 December 1984 [PEN.016.1294]

his patients who asked him, whether or not they had the antibody. Frances' evidence of her father's position shows that some patients did take this on board. He sought and received his results on 21 December. However, the limitations of the meeting, and the scope for confusion that it generated, is attested to by the fact that two of Dr Alison Richardson's patients, both of whom had tested positive, left the meeting believing that they were negative. They believed that if they had been positive they would have been told that at the meeting. Professor Ludlam said that he was devastated on first hearing the news that some of his patients had tested positive. In all the circumstances, it is not surprising that haemophilia patients and their relatives, hearing the same news, should find it difficult to take in any information subsequently imparted. On any view, the meeting was an inappropriate means of conveying such news and any advice consequent upon it, although the Inquiry recognises that the media pressure probably left little room for choice in how to proceed.

**33.399** Given the obvious limitations of the meeting some follow-up was clearly required. It is unfortunate that the covering letter Professor Ludlam sent with the circular on AIDS has not been recovered. His evidence that it would have mentioned that some patients 'in Scotland' had tested positive is consistent with other evidence of the degree of specification in his public statements, as is the invitation to his patients to make an appointment to discuss their position. That evidence is accepted.

**33.400** It is clear, however, that Professor Ludlam's patients were not invited on an individual basis to attend the Edinburgh clinic. Whether patients had tested positive or negative for the antibody, Professor Ludlam had information about their health that they might have chosen to know. He could not have insisted on informing them but he could have followed the course adopted in Glasgow, at least from the summer of 1985, and sent an appointment to each patient inviting them to come individually for an interview. Such an invitation would have focused the recipient's attention on this important issue. In the climate of the time, some of them might have decided to remain in ignorance, since testing in itself, regardless of the result, might bring about adverse financial consequences. However, such a decision should have been theirs. That there was no treatment at the time would have been, no doubt, a factor in the patient's decision whether or not to discover if they had been tested. It is a matter of regret that Professor Ludlam did not issue such individual invitations. As a result, information reached his patients on a piecemeal basis over a long period of time and some were left ill-informed.

## Mark

**33.401** Mark's case is perplexing. Ms Reynolds' evidence cannot be accepted as it has no adequate time reference and is in too general terms to have dealt with the long period of time that passed before Mark was told of his diagnosis. During much of that time, Mark was seen by another doctor. Professor Ludlam explained that he felt that it was important for Mark to know of his diagnosis on a number of grounds. He spoke of an initial unsuccessful attempt to tell him in 1986, detailed in his notes, together with two further attempts. One was, potentially, to visit his home and the other was when he was seen by, as Professor Ludlam put it, 'one of our very able young doctors'. That doctor was Bernadette Auger. Dr Auger's note dated 20 March 1989 is a clear, contemporaneous and full account of her consultation with Mark and is accepted as accurate, true and reliable.<sup>523</sup>

---

<sup>523</sup> See Chapter 5, *An Examination of the Effects of Infection with HIV on the Patients and their Families, Including Treatment*, at paragraph 5.249

It cannot be reconciled with Mark's evidence and especially the frequent repetition of the recollection that he always said: '[t]ell me if there's anything wrong', in resisting detailed information about test results. It appears that Mark did resist information about his test results more generally and that that was understood by the clinicians treating him.

**33.402** There was considerable discussion with Professor Nathanson about this situation. The developing knowledge about AIDS was relevant. In 1984 the implications of a positive diagnosis were unclear. As Professor Nathanson explained, by 1988 it had become clear that positive antibody status usually meant that the patient had the virus and that the prognosis was very poor. From 1984 to about 1988 there was effectively no treatment for the condition. However, from about 1987–88 doctors were aware that an HIV positive patient was susceptible to certain AIDS-related conditions which had to be treated quickly and aggressively with antimicrobials.<sup>524</sup> In particular it was important to treat a patient quickly with pentamidine if they developed PCP.<sup>525</sup>

**33.403** Professor Nathanson's general evidence has been set out at length. So far as it bears on Mark's case, it can be summarised:

- A doctor could not force a patient to know the results of tests.
- A patient who refused to learn his results should be advised to act as if positive, so as to protect others.
- As means of helping infected patients developed – specifically with the introduction of antiretroviral medication in this case – the doctor would increase pressure on the patient to know the results.
- A point could be reached at which the doctor might consider forcing the knowledge on the patient because of the advantage of obtaining treatment.
- Before 1988 a doctor could not be criticised for not forcing patients to hear the results of tests.

**33.404** Applying the ethical rules and guidelines, as outlined by Professor Nathanson, it is not possible to find that Professor Ludlam was in breach. It is fortunate that in Mark's case his contemporaneous medical records assist in determining what probably happened over two decades ago. Conversations, at such a distance in time, are unlikely to be remembered accurately by their participants although the gist may remain clear to them. It is, of course, difficult to explain the difference between Mark's evidence and that of the practitioners treating him. It is trite that the message spoken is not always the message heard. For obvious reasons, medical practitioners would be particularly concerned to advise those testing positive of their results. Mark does not dispute that he was seen on a number of occasions where reference was made to his test result. It may be that he assumed that if he was positive the result would simply be passed on to him. That was not the policy at the RIE until treatment considerations arose. Whilst being offered a test result on a number of occasions might alert some to the probability that the result was positive, it would not do so with others. There is no doubt from his evidence, and that of Professor Ludlam, that when Mark received his diagnosis, he was surprised. He does not seem to have assumed from the attempts to tell him his result that it was, in all probability, because it was positive. Mark's evidence that he was 'stunned' on hearing the news of his diagnosis, is accepted.

---

<sup>524</sup> Professor Nathanson – Day 37, page 123

<sup>525</sup> Ibid pages 174–175

## Glasgow

**33.405** It is not possible to reconcile the several sources of evidence of practice at the GRI, from Professor Forbes, Professor Lowe and Dr Wilkie. Specific difficulties with their evidence have been noted above. How and when patients were told the results of anti-HTLV-III testing is unclear.

**33.406** Dr Follett had clearly been carrying out some HTLV-III tests as early as January 1985. The notes in David's case are unequivocal: he was tested and found HTLV-III negative on 25 January 1985. That was before any counselling protocol had been considered, much less implemented, and in particular was probably before Dr Wilkie became actively engaged in advising haemophilia patients about HTLV-III infection.

**33.407** The circular letter dated 8 January 1985 which was sent to all patients registered at the West of Scotland Haemophilia Centre at the GRI contained no indication that the individuals found positive had been, or indeed would be, informed of the positive findings in their cases. On the contrary, the clear indication was of a new initiative to investigate virus exposure and monitor all patients who had received concentrate therapy.

**33.408** From its terms, the letter of 8 January 1985 sent to patients registered at the Glasgow Centre was not addressed to people who were expected to have had prior knowledge of the results from the tests carried out by Dr Gallo or who had attended the meeting on 19 December 1984. Nor did it indicate that among the patients addressed were some for whom test results were available. The opening paragraph, referring to newspaper and television reports, would not be appropriate in a letter addressed to individuals who had been invited to a meeting at which Professor Forbes and Professor Ludlam had spoken on the topic of AIDS. The invitation to attend and have a test which 'we ... now' had available, despite the prior knowledge that 10% of patients had already been found antibody positive, may appear obscure unless the 'we' is taken as meaning Glasgow. The original testing was done in the USA. In any event, whatever reservations may exist in relation to the wording of this letter, it is clear from its terms that the recipient of it would not be aware after reading it that he had been tested and could obtain his results from the centre.

**33.409** There is no contemporaneous documentation to corroborate Professor Forbes' recollection of communicating the results of the Gallo tests 'as soon as possible' after November 1984. Whilst Professor Lowe, who has a good recollection of events, made it plain that it was his colleague's clear intention to do so, he also indicated that Professor Forbes had reservations about the accuracy of the Gallo test. Professor Forbes said in his evidence that he considered that confirmatory testing of the Gallo results was necessary. Neither Professor Lowe's evidence nor Dr Wilkie's suggest that either of them dealt with any patients who had received their Gallo test result. There can be no doubt, in the climate of AIDS fear then extant, that any patient advised of a positive result would be likely to consider it something akin to a death sentence. The catalyst for the appointment of Dr Wilkie, a social scientist, appears to have been the obtaining by Professor Forbes of the positive test results, suggesting that he was alive to the possible social and economic consequences of a positive diagnosis. Undoubtedly, Dr Wilkie will have further refined Professor Forbes's understanding of the likely impact of a positive result. Other documentation suggests that HTLV-III test results were communicated at the earliest after March 1985 and, in some cases, after 1986. In the circumstances, it seems probable that

Professor Forbes changed his mind and decided not to pass on the results obtained by Dr Gallo's unlicensed tests until they had been confirmed by Dr Follett. Whilst that sequence of events may not accord with Professor Forbes' memory, it would be consistent with his colleagues' high opinion of him and understandable in the circumstances then prevailing.

### David

**33.410** Professor Lowe's evidence, and that of Dr Wilkie, suggested that the policy at the GRI was that patients should not have their blood tested for HTLV-III before they had received counselling about the implications of the test. Regrettably, this does not appear to have happened in David's case, and his evidence in this matter is accepted. It seems, from the medical records, that when he was seen in January 1985 he was negative for the virus and was provided with Haemophilia Society leaflets. Dr Wilkie only began interviewing patients in the late summer of 1985. When David was seen on 8 November 1985 it was by an unknown doctor, who appears to have taken blood and submitted it for testing without either obtaining consent for the test or providing counselling. Consequently, when Professor Lowe saw David on 2 December 1985, his patient had not been prepared for receipt of his results. In the circumstances, it is entirely understandable that David should have felt angry. His reaction confirms the wisdom of the counselling programme pioneered at the GRI, but suggests that it did not always proceed as intended.

**33.411** David's evidence about the manner in which Professor Lowe told him his diagnosis gives one patient's perspective of receiving such information from a clinician. It is, perhaps, illustrative of the difference which may sometimes exist between how a clinician believes he is conveying such a diagnosis and how the patient perceives he has been told of the diagnosis. A number of factors, in addition to the clinician's manner, will affect this perception. Breaking bad news is never easy, and Professor Lowe candidly admitted that he found providing such a diagnosis a difficult task to perform.

### *General comments*

**33.412** Until the events of 1982–84, and the questions relating to providing information to patients in 1985 and later, which raise specific issues, routine testing of patients' blood ancillary to diagnosis and the prescription of proper care and management was standard practice. Consent was not normally sought for specific investigations, as distinct from the physical act of taking blood which could clearly not take place without the patient's consent, either express or implicit, in the act of extending an arm for preparation by ligature, puncture and for the withdrawal of blood. Dr Winter's written evidence to the Archer Inquiry (see paragraphs 33.176 to 33.180 above) is accepted. For a considerable period before 1988, clinicians saw it as part of their responsibility to their patients to monitor for infections. It was perceived to be a core part of patient care and not something to be discussed with patients.

**33.413** It is an almost inevitable consequence of the paternalistic attitudes in the early 1980s together with the relative ignorance of the significance of the AIDS virus at that time, that in the absence of appropriate professional guidance some clinicians would consider AIDS-related investigations to have the same character as established investigatory/monitoring tests for which no specific consent required to be sought. The rate at which doctors realised that this new infection required a different response, particularly in regard to the provision of information and the obtaining of consent for testing, would vary within the profession. Such realisation of the need for a change of approach would depend upon many things including experience and attitude.

**33.414** As events were to prove, but unknown to clinicians generally until 1984, AIDS transmitted by an infective agent was a material risk associated with all forms of factor therapy in the early 1980s. The commercial pharmaceutical industry responded to the risk by introducing early forms of heat-treated products in 1984, although evidence of their effectiveness was lacking at that stage. Selection of products for therapeutic use had become more problematical. It is from mid-1984 and into 1985 that issues relating to the provision of information about the products offered and about the risks associated with them became real, ultimately giving rise to a need for informed consent to treatment on the part of the patient.

**33.415** There is a distinction between the risk of transmission of AIDS and the risk of transmission of NANB Hepatitis which it is important to note. AIDS was a new disease. With the exception of those patients being introduced to factor therapy for the first time, most coagulation disorder patients at risk of NANB Hepatitis would have been exposed to the infective agent (usually the Hepatitis C virus, as events were to show) before it was realised that the risk of transmission was virtually universal from first treatment with factor concentrates, of whatever origin. When that was appreciated, there was little that could be done to protect established patients. AIDS presented a new and distinct risk to long-established patients as well as to previously untreated patients. When the risk became real, it was greater for patients with severe coagulation disorders, for whom effective therapy required heavier concentrate usage. It was also greater for those using commercial concentrates. Since a majority of those established on concentrate therapy in the early 80s were patients with severe coagulation disorders, there was a risk that a very significant proportion of patients would contract AIDS. The risk was higher in England and Wales due to their greater reliance on commercial concentrates.

**33.416** A very significant number of patients did develop AIDS. This was not anticipated, however, and was not generally understood until late 1984 or later. Some clinicians in England and Wales did change from concentrate therapy to the use of cryoprecipitate in 1982 and 1983 but that was by no means general. The priority remained the provision of effective treatment for haemophilia and other coagulation disorders. That is the practical context in which the ethics of clinical practice must be considered.

***Scottish practice: the ethics of providing information about HIV/AIDS, risk from treatment and seeking consent***

**33.417** It is clear from Professor Nathanson's evidence that today failure to discuss treatment with patients and to obtain their consent to treatment would be unacceptable. That appears from the General Medical Council booklet *Consent: patients and doctors making decisions together* discussed in Chapter 32, *An Investigation into the Systems in Place for Informing Patients about the Risks – Ethical Context*.<sup>526</sup>

**33.418** In contrast to her evidence on practice in relation to HCV, there was little controversy about Professor Nathanson's evidence relating to the ethical principles and rules applicable to clinical practice in respect of HIV/AIDS in relation to the late 1980s.

**33.419** In respect of the provision of information relating to tests, again, context is important. As described by Professor Ludlam and Professor Forbes, routine blood tests were long-standing aspects of the treatment, or management, of the patient as an individual

---

<sup>526</sup> *Consent: patients and doctors making decisions together*, GMC, 2008 [PEN.018.0430]

and provided information of immediate clinical importance to the patient. However, it is also apparent that in any teaching hospital with a research agenda, the accumulation of data from testing individuals would inevitably have wider significance, increasing general knowledge of the index condition and the direct effects and side-effects of any treatment that followed. It would not be unreasonable to expect the individual patient to understand that his data contributed to the general store of knowledge from which all other patients in the care of the one clinician or clinical team would take benefit and to expect that he would similarly benefit from advances in knowledge achieved from the management and investigation of other patients.

**33.420** It is really inconceivable that it would be otherwise. Ordinary clinical practice, as described by Professor Ludlam, involved discussions in the course of ward rounds with junior doctors and students. Research projects were discussed, and patients were asked to cooperate by participating, in the ordinary course of events. In the real world of medical wards in teaching hospitals, patients are not insensitive to what happens around them. While his research interests, or those of his colleagues in Glasgow, may not have been understood, that they had research interests would have been known to regular patients and, through them, to the close community of coagulation disorder patients attending the hospitals as a whole.

**33.421** It follows that a clinician intending to carry out a particular testing programme should have been conscious of the need to structure the approach adopted and, in particular, the information given to patients about the tests and any consent sought for the tests to be carried out, so as to reflect the likelihood that some information at least would become widely known among patients, as well as having a wider professional application. So far as the evidence shows, the issues around the approach to testing arose first in Edinburgh and Glasgow in relation to the immunological studies carried out on haemophilia patients in 1983.

**33.422** As set out in paragraphs 33.173 to 33.174 above, the considered view of the UKHCDO in December 1984 was (a) that testing of patients should proceed; (b) that it was for individual clinicians to decide, having regard to the circumstances, whether an individual testing anti-HTLV-III positive should be informed of the result; and (c) that advice should be given to patients about the risks associated with sexual transmission and steps to be taken to protect spouses and other partners. There was no stipulation in Professor Bloom's advice of 14 December 1984 for patient consent to testing. Indeed it can be inferred that consent was not considered to be required since disclosure of the result was discretionary and that is inconsistent with a principle of patient involvement in the decision to carry out a test in the first place. This is significant in considering the steps taken in Edinburgh and Glasgow, since the advice of the Reference Centre Directors is a clear expression of the ethical stance of this professional group at a critical time in the evolving picture. It is important to bear it in mind in considering Professor Nathanson's evidence.

**33.423** Professor Nathanson explained that in order to carry out an HIV test in accordance with BMA and GMC guidance current from 1988 it is necessary to (i) obtain a patient's valid consent and (ii) ensure that the results are offered to patients. She said that in current practice clinicians are expected to offer 'pre-test counselling' to patients before HIV testing. This will include full information about the test and the implications of a positive result. The practical result of following this procedure is that, if a patient tests positive, they will already know the implications of the diagnosis. Pre-test counselling

helps to remove some of the shock and surprise that a patient might experience on being told of a positive diagnosis.<sup>527</sup>

**33.424** It is clear that the practice described by Professors Ludlam and Forbes of taking an apparently routine blood sample from a patient on an apparently routine visit, storing it in the deep freeze and later sending it for an HTLV-III antibody test without informing the patient would not be acceptable today. It is also clear, however, that standards were different in 1984.

**33.425** As Professor Nathanson noted:

When the first diagnostic test for HIV disease (in fact a test for antibodies for what was then called HTLV III) became available in 1984 there was considerable debate over whether those for whom a test might be considered clinically relevant needed to be asked for consent to the test.<sup>528</sup>

**33.426** In the early days of testing many believed that HTLV-III antibody tests could and should be carried out without consent and that taking blood for the test at the same time as other routine medical tests would mean that necessarily implied consent had been given.<sup>529</sup>

**33.427** Professor Nathanson expressed the view that, while testing for HTLV-III antibody without consent was not the 'gold standard' of medical practice, it was common practice in the early 1980s. She said that she would not be critical of clinicians who had not conducted their practices in accordance with the 1988 guidance before that date. She explained that, until the GMC guidance was published, much of the advice on consent concerned consent to treatment rather than consent to testing. The advice published by the GMC in 1988 helped to close the argument about consent for testing.<sup>530</sup> She explained:

The question is: does that mean that anything that the doctor wants to test that blood for, you have given necessarily implied consent for? And I would say that in the mid 1980s that was the issue about which people were discussing, and I think we really came to the conclusions that you might say that there were certain tests that were so routine, that are so often done, that you were necessarily consenting to them without being given the details.

....

But it was felt [by the date of publication of the GMC 1988 guidance] that a test for HIV was sufficiently different because of the clinical uncertainty, what did a result mean, and because of the social consequences, that you needed to get a specific consent to say that.<sup>531</sup>

**33.428** Professor Nathanson said that the current approach to HIV testing has not changed much since the 1988 guidance, which applies to consent to testing as much as it does to treatment. In contemporary practice clinicians are expected to offer full information to patients about all tests they intend to perform. To supplement the basic guidance set out in *Good Medical Practice*, the GMC produces a booklet on consent. 'Good medical

---

<sup>527</sup> Professor Nathanson – Day 37, pages 37–39

<sup>528</sup> Professor Nathanson's first report to the Inquiry [PEN.012.0330] at 0336

<sup>529</sup> Ibid [PEN.012.0330] at 0336

<sup>530</sup> Professor Nathanson – Day 37, pages 92–93

<sup>531</sup> Ibid pages 90–91

practice' is not a body of formal rules, however, but rather a set of principles and values on which good medical practice is founded. The supplement, *Consent: patients and doctors making decisions together* (May 2008) provides more specific advice.<sup>532</sup> The clear advice is that testing for HIV now requires specific consent.

**33.429** However, Professor Nathanson explained that the 1988 guidance was the first time that the GMC was explicit on the topic. In the late 1970s, it would have been extremely rare to tell patients everything about their care. The 1988 guidance was part of the 'evolution towards patient-centred care'.<sup>533</sup> She said that between 1984 and the 1988 guidance, not fully informing the patient 'wasn't best practice but it was understandable and widespread and something that was becoming less understandable and less widespread, if you like, diminishing'.<sup>534</sup>

### *Glasgow and Edinburgh compared*

**33.430** At the end of 1984, Professors Forbes and Ludlam found themselves in the position of having HTLV-III test results for some of their patients. Those tested were unaware of the tests and, in many cases, unaware that they were even at risk of infection. Obviously, no pre-test counselling had been carried out. The initial attempt to communicate the existence of such results to east of Scotland patients at the meeting was largely ineffectual. Attempting to communicate such sensitive and life-shattering information by such means was ill advised. The response in the west of Scotland was more conventional and, in the long run, seems to have been more effective.

**33.431** At the end of 1984 there was no consensus amongst haemophilia clinicians in relation to the communication of HTLV-III test results to patients. There were effectively three schools of thought on this matter:

1. All patients should be told their test results regardless of their wishes.
2. Patients should not be told their results and should all assume that they are positive.
3. Patients should only be told their results if they asked for them.

**33.432** Professor Nathanson recognised that the situation was 'extraordinarily difficult' and that many doctors did not communicate results of HIV tests.<sup>535</sup> She explained, however, that in 1984 the 'gold standard' for a clinician in that position was to offer the information to their patients. In Professor Nathanson's view, Professor Ludlam's approach of offering his patients information rather than simply telling them their results, and thus forcing them to know their antibody status, was reasonable. It would not have been up to the 'gold standard' for Professor Ludlam to have either withheld the test results from patients or to have told the patients their results without ascertaining whether or not they actually wanted to know them. Professor Ludlam's approach of not telling patients their test results unless they asked for them was consistent with the UKHCDO advice and it is clear that many doctors at that time considered that testing for HIV was simply an extension of the monitoring of patients which was already being done.

**33.433** Professor Nathanson said that she would be critical of a clinician who had test results for his patients but did not make it clear to them that results for them were available.

<sup>533</sup> Professor Nathanson – Day 37, pages 113–114

<sup>534</sup> *Ibid* page 118

<sup>535</sup> *Ibid* page 125

She felt that the way to do that was by writing to them. While this is more of a practical consideration than an ethical question, in her view a clinician who has decided to offer his patients information about their test results (and many did not at that time), in order to do so properly had to tell the patient clearly that information about them was available. When asked about how to approach communicating results she said:

I think that really depends upon how often you see the patient and what the relationship is with the patient. That would be equally true today in the sense of communicating results. The clear issue is of course to make sure that the patient knows, or is given the availability of that knowledge, as early as possible.

In 1984 that would almost certainly have meant writing to patients and saying, "We have information available, please make an appointment to come and see me if you want to know that information." If you have patients that have routine appointments within the next few weeks, you could probably not write to that group but you must make sure that they are seen, and if by any chance they don't come to those appointments, then make sure they get an offer of another appointment quickly.<sup>536</sup>

**33.434** Professor Ludlam was told by the reporter from *The Yorkshire Post* that he intended to publish the details of the positive test results in the Edinburgh haemophilia population. The Inquiry has not heard evidence from the reporter concerned. It is almost certainly the case that information was leaked to the newspaper by a person to whom it had been imparted on a confidential basis. The motives behind the decision by the newspaper to prepare and publish a report are not known. But the involvement of the paper was the immediate cause of hasty resort to a public meeting. This was an unsuitable mechanism for release of such sensitive information about the health of patients.

**33.435** Dr Wilkie described, graphically, attitudes to HIV-positive individuals at about that time. She explained that they were viewed as 'lepers', or 'dirty patients' and subjected to humiliating, and unnecessary, precautions in order to ensure that they did not infect others.<sup>537</sup> Out of fear of such consequences, sufferers routinely concealed their diagnoses. However, unlike the other groups particularly at risk of the infection such as IV drug users or homosexuals, haemophilia sufferers tended to be known in the communities in which they lived, their condition unconcealed from family, friends, workmates and acquaintances. Having begged the reporter to delay publication, and been allowed one week, Professor Ludlam wrote invitations to the meeting that same day. As a vehicle for the transmission of sensitive information, the meeting's shortcomings do not require to be re-rehearsed here. Considering the need to get information to as many patients as possible, imparted by him personally and as quickly as possible, it was the option he chose. It would not have been, he explained to the Inquiry, his 'first choice, given a completely blank sheet and without other constraints'.<sup>538</sup>

**33.436** It is clear from the evidence that Professor Ludlam attempted to prompt his patients into inquiring about their test results by means of the meeting, the circular and the covering letter. If they attended the RIE, he decided, depending upon the circumstances of

---

<sup>536</sup> Ibid page 128

<sup>537</sup> Dr Wilkie – Day 32, pages 64–67

<sup>538</sup> Professor Ludlam – Day 35, page 116

their visit, whether to initiate a conversation about AIDS or encourage them to seek their results. His approach was based, in part, on his awareness of the consequences for them of knowing that they had been tested, and the significance of a positive or a negative result. It is clear that he considered two matters of particular relevance in making that decision. Firstly, the fact that no treatment for the condition then existed and, secondly, the fact that all haemophiliacs were being advised to adopt precautions as if they were infected. If a patient did not attend the RIE no communication was sent to them as a further prompt.

**33.437** Despite the meeting of 19 December, the circular and these discussions, Professor Ludlam did not make it *sufficiently* clear to all of his patients that they had to ask him if they wanted to know their results. He could have made appointments for every patient who used factor concentrates to be seen by him, by Mrs Brown or by both. He could have sent out appointments with the circular in the way Professor Forbes did with his letters of January and April 1985. He could have started with the 40-50 patients who had already been tested. He could have met with patients in early 1985 and made sure that they were individually fully aware of the situation, that he had HTLV-III test results for them, where that was the case, and that he would give them the results if they asked for them. He could have been more explicit about this without insisting that they knew their test results. If Professor Ludlam had done something along these lines, it is likely that by the end of 1985 all patients would have known their HTLV-III status except for patients who did not want to know.

**33.438** In the result, some patients were angry that they had not been told of their diagnosis sooner or at all, and some were glad that they remained in ignorance for so long. As might be expected, as his knowledge of the virus and its effects increased and the possibility of treatment emerged, Professor Ludlam became increasingly proactive in his approach. To modern sensibilities, paternalism and the 'Doctor knows best' approach are anathema but in considering judgements made in the early and mid 80s, it has to be taken into account. A quite different approach would be taken nowadays but that is in large part because of the effect that the emergence of the AIDS virus has had on medical ethics.

**33.439** The position in the west of Scotland is complicated by the inconsistencies in the evidence relating to it, and Professor Forbes' memory difficulties. On balance, it is concluded that the only testing carried out prior to that executed by Dr Follett was that done in the USA by Dr Gallo. Further, it is concluded that, despite his recollection to the contrary, Professor Forbes did not pass on the results of the Gallo tests to his patients before confirmatory testing was undertaken by Dr Follett. It is clear that it was his intention to pass them on, Professor Lowe attested to that fact, but the evidence suggests that Professor Forbes must have changed his mind and the reservations he expressed about the reliability of the research assay provide both an explanation and a justification for that course of action. It cannot be concluded that that practice, in itself, involved any breach of the norms of ethical behaviour of the time.

**33.440** It should be noted that with the emergence of AIDS, an entirely new disease, almost all haemophilia clinicians found themselves in an extraordinarily difficult situation. Due to the chronic nature of haemophilia, those clinicians had known and treated many of their patients since childhood. They had seen many of those patients' lives transformed

by the introduction of concentrates, and rejoiced with their patients. As knowledge of the AIDS virus increased, so did the realisation amongst those clinicians that the treatment they had prescribed to alleviate their patients' primary condition, had also transmitted a potentially fatal viral infection. In the early days, they knew almost nothing about the disease and its natural history and could themselves only pass on the little they knew. As more was learnt about the virus, they endeavoured to alter their practice in accordance with that knowledge. They had received no guidance or training for the unprecedented circumstances in which they found themselves.

**33.441** Whilst initially the medical profession knew little about AIDS, those they were treating knew less and depended upon the professionals for guidance. In a paternalistic age, those providing such guidance aim to reassure and to comfort the patient, on the basis that 'Doctor knows best'. Equally, those receiving such guidance do not tend to question it, feeling entitled to rely upon it. Inevitably, if that guidance proves wrong and patients suffer, or die, in consequence of it, some of those patients may, entirely understandably, feel both angry and betrayed. If a new, potentially fatal disease like AIDS were to emerge today it is likely that patients would be made aware of the medical profession's ignorance of it and share all the uncertainties and anxieties consequent upon that. Unfortunately, patients would, in all likelihood, still suffer and die. Anger against the disease and all of its consequences would probably be felt. But there would be no sense of betrayal. On the evidence, in relation to the procedures adopted for testing patients' samples for HTLV-III and the communication of test results, there was no breach in Edinburgh or Glasgow of any rule or principle of ethical conduct then applicable. In the circumstances, where many patients died, and many continue to suffer today, some crumb of comfort may be gained from the fact that due to HIV/AIDS and its fallout, all patients must now be treated in a patient-centred way and the last vestiges of paternalism have largely been swept away. Being informed is now the patient's prerogative.

## CHAPTER 34

### AN INVESTIGATION INTO THE SYSTEMS IN PLACE FOR INFORMING THE PATIENTS ABOUT THE RISKS – HEPATITIS C

#### Introduction

**34.1** The discussion in Chapter 33, *An Investigation into the Systems in Place for Informing the Patients about the Risks – HIV/AIDS*, sets the scene for this chapter. The previous chapter dealt with relationships between doctors and patients, from the beginning of the AIDS epidemic in 1982 to about 1985, with particular reference to HIV/AIDS. In that period, it became clear that NHS blood disorder patients had acquired the HIV virus and the focus in clinical and ethical practice shifted towards the management and care of patients infected, or suspected to be infected, with that condition. The lessons learned in that context were available to instruct doctors in the management and care of patients, as it came to be understood that non-A, non-B Hepatitis (NANB Hepatitis) was a potentially more serious disease than had generally been thought up to the end of 1985. In that period NANB Hepatitis was not entirely overlooked, even at the height of the AIDS epidemic. For the most part, however, it was a secondary consideration in an environment dominated by the threat of AIDS.

**34.2** Developing knowledge of viral hepatitis has been traced in Chapters 14–16, *Knowledge of Hepatitis 1 to 3*. This forms the background to the discussion that follows.

#### Scope of the chapter

**34.3** This chapter deals with the evidence on the information and advice given to patients, and where appropriate to their parents, in Scotland in the course of the reference period with regard to NANB Hepatitis/Hepatitis C. More specifically it considers:

- Questions relating to the choice of therapeutic products in treating blood coagulation disorders and, in particular, understanding the risks of contracting NANB Hepatitis, from 1974 onwards.
- The information given to patients about those risks.
- The investigation and management of patients' conditions with regard to symptoms of NANB Hepatitis/Hepatitis C.
- The understanding of risks associated with HCV once tests for infection had become available, including pre-test counselling.
- The communication of results to patients who were found to be infected with HCV.
- Practices at centres in Edinburgh, Glasgow and Dundee are examined in some detail as these developed over the reference period. Practitioners from these centres were able to give evidence to the Inquiry in relation to practices there.

#### Background

**34.4** The information available to doctors on which to base their advice to patients, having regard both to what was generally accepted in the medical profession and what was in the public domain, varied widely both over time and across the UK and other western countries. In Chapter 32, *An Investigation into the Systems in Place for Informing Patients about the Risks – Ethical Context*, Dr Charles Hay's evidence was relied upon as illustrating

best clinical practice. That was appropriate since in some respects his practice reflected at an early stage an understanding of NANB Hepatitis that was not shared generally and involved a more demanding level of communication of NANB Hepatitis infection than would have been practised elsewhere. In this chapter it is appropriate to take note of distinctions between Sheffield, one of the places where he worked, and other centres.

**34.5** As noted in Chapter 21, *Haemophilia Therapy – Use of Blood Products* paragraphs 21.161–21.171, on 26 April 2011 the Inquiry viewed two *World in Action* documentaries called ‘Blood Money’ which were first transmitted in 1975.<sup>1</sup> The programmes dealt with blood products and the transmission of viral infections in haemophilia patients receiving replacement therapy with factor concentrates. The programmes did not deal with the risks of transmission associated with transfusion of whole blood or blood components in general medical and surgical practice. In relation to HBV, which was then understood to be the main pathogen threatening recipients, the programmes were explicit reminders, if reminders were needed, that the risk of transmission of viral hepatitis was inherent in factor replacement therapy.

**34.6** In one respect at least, patients with haemophilia or other blood coagulation disorders, or the patients’ parents, were in a better position to inform themselves of risk than others receiving transfusions. It was clear from what patients and their parents said in the television documentary that in the 1970s many haemophilia patients were aware that there was a risk of contracting hepatitis from the use of factor concentrates. In the later years of the decade, there was published material on the risk of transmission that was available to members of the Haemophilia Society. David Watters, General Secretary of the Society between 1986 and 1994 (and Coordinator for five years before that), explained that this risk was discussed in Haemophilia Society Newsletters from 1978.<sup>2</sup> It is clear from the evidence of clinicians noted later in this chapter that the Society’s leaflets were in circulation in haemophilia centres. There was a body of shared information, often backed by expert authors and commentators, available to patients and haemophilia clinicians alike.

**34.7** The natural history of NANB Hepatitis was not well understood, however, until the second half of the 1980s, at the earliest.<sup>3</sup> In the mid-1970s discussions of viral hepatitis almost certainly referred to the then well-known risk of contracting Hepatitis B. By 1975, screening for Hepatitis B Virus (HBV) in blood donations had become standard practice in the USA and in Europe, though high sensitivity in screening tests was not achieved until the end of the 1970s. Progressively, there was increasing confidence in the effectiveness of the methods used to identify infected blood and to exclude it from therapeutic use.

**34.8** The extent of the problem of transfusion-associated transmission of NANB Hepatitis did not begin to become apparent until about 1978.<sup>4</sup> Even then it was not generally thought to present a risk of comparable order to the risks associated with bleeding in coagulation disorder patients. Until the later 1980s there was no general consensus in the medical profession that NANB Hepatitis infection was associated with serious liver disease. Even at that point, some commentators thought that the condition was not a matter of serious clinical concern.

<sup>4</sup> See Chapter 15, *Knowledge of Viral Hepatitis 2 – 1975 to 1985*

**34.9** For the purposes of this chapter, it is interesting to compare the treatment of NANB Hepatitis in successive editions from around this period, of Dr Peter Jones' (Newcastle Haemophilia Reference Centre) book, *Living with Haemophilia*. The book is a guide that was widely distributed among patients and their families. The first edition, published in 1974, discussed 'serum hepatitis' briefly and described its transmission by the 'Australia', or 'hepatitis-associated', antigen. It was presented as a rare but important side-effect of blood transfusion. The second edition was published in 1984. The book now dealt with Hepatitis B extensively, less so with Hepatitis A, and only briefly with NANB Hepatitis. It identified hepatitis generally, inflammation of the liver, as one of the most important side-effects of blood transfusion. It commented that, 'if the infection is marked enough jaundice may result', and continued:

We know that many liver infections are not severe enough to result in the appearance of jaundice; they show themselves as mild, transient periods of feeling unwell, or only as changes in liver function measured in the laboratory. One of the reasons for following up people with haemophilia carefully is to monitor these changes.<sup>5</sup>

**34.10** The second edition of the book noted the three types of viral hepatitis then known and said:

Hepatitis non-A, non-B results from infection with one of at least three viruses, none of which has ... been positively identified in the laboratory ....<sup>6</sup>

**34.11** It commented on the NANB Hepatitis viruses:

The incubation periods for these viruses appear to be short, in some cases only a matter of days. There is evidence that haemophiliacs have multiple episodes of NANB Hepatitis, most going unnoticed, although the first attack is sometimes accompanied by the appearance of jaundice. The NANB agents are important because, as with hepatitis B, the infection they cause can lead on to chronic liver disease. No way of protecting recipients from NANB Hepatitis is known.<sup>7</sup>

**34.12** The third edition (1990) introduced the term 'transaminitis' for the 'condition', identified by changes in liver function measured in the laboratory.<sup>8</sup> The comment on NANB Hepatitis was in substantially the same terms as the 1984 edition, but added that donor testing for Hepatitis C was just being introduced.<sup>9</sup> Dr Jones did not equate 'transaminitis' with NANB Hepatitis or otherwise suggest that liver function test biometrics were monitored as specific indications of infection with NANB Hepatitis.

**34.13** There were two parallel trends: increasing confidence in the effective screening of donations to exclude blood infected with Hepatitis B and slow, and late, developing knowledge of the serious risks associated with NANB Hepatitis. Dr Jones' comments in the 2nd edition of his book indicate that by 1984 he was taking a more serious view of NANB Hepatitis than he had in the 1974 edition. These books form important background material in considering the provision of information and advice to patients who, generally, had underlying blood coagulation deficiencies that exposed them to the risk of serious, and in some case life threatening, episodes of haemorrhage.

<sup>9</sup> Ibid [PEN.018.0761] at 0765

**34.14** In their 1974 report, the UK Medical Research Council (MRC) Working Party on Post-Transfusion Hepatitis included in their definition of 'hepatitis' a finding of enzyme elevation in association with other clinical indications of hepatitis, typically jaundice.<sup>10</sup> Since this was a definition of 'hepatitis' generally, it was as applicable to the postulated NANB Hepatitis as it was to Hepatitis A and B.

**34.15** In August 1975, Dr John Craske of the Public Health Laboratory, Dorset, published data on an outbreak of hepatitis following the infusion of commercial Factor VIII in the Bournemouth Haemophilia Centre.<sup>11</sup> The criteria for diagnosis were jaundice or raised transaminase levels associated with compatible history and clinical signs of infection.<sup>12</sup> With this publication, NANB Hepatitis had been recognised and reported from a UK haemophilia centre.

**34.16** In 1978 doctors at the Royal Hallamshire Hospital, Sheffield, published the results of liver biopsies carried out on haemophilia patients with persistent abnormal liver function test results.<sup>13</sup> A wide spectrum of chronic liver disease was found that bore no relationship to clinical history or biochemical findings using tests available at the time. They concluded that a large proportion of haemophilia patients receiving treatment with Factor VIII had chronic liver disease and that NANB Hepatitis may well have been an important factor. This was supported by observations in half of the cohort of patients studied. The paper did not say that abnormal liver function amounted to a diagnosis of NANB Hepatitis but it provided evidence that a clinical history of hepatitis was not essential for proof of infection.

**34.17** On 4 July 1981, an editorial in the *British Medical Journal (BMJ)* stated that a NANB Hepatitis diagnosis was usually inferred from abnormalities in the results of hepatic biochemical tests rather than from clinical evidence.<sup>14</sup> It referred to the biopsy-based research at Sheffield as indicating that changes in liver architecture were consistent with previous viral assault. The editorial also referred to Scottish research by Stirling et al. That research looked at Edinburgh patients treated with SNBTS Factor VIII who, followed over a five year period, had no symptoms or other objective clinical evidence of liver disease but did have ALT abnormalities. The authors suggested that, 'Possible causes include repeated infection with as yet unidentified non-A, non-B hepatitis viruses'.<sup>15</sup>

**34.18** The next stage was the research initiated by Dr Hay following his return to Sheffield in 1983 that resulted in publication in 1985 of the provocatively entitled article, 'Progressive Liver Disease in Haemophilia: An Understated Problem?'.<sup>16</sup> In the interval between 1978 and 1985 Dr Hay and his Sheffield colleagues were in the vanguard in recognising NANB Hepatitis as a potentially serious condition and in reporting it in the

<sup>10</sup> Medical Research Council Working party on Post-Transfusion Hepatitis, 'Post-transfusion hepatitis in a London hospital: results of a two-year prospective study', *Journal of Hygiene*, 1974; 73:173–188 [LIT.001.0116]

<sup>11</sup> Craske et al, 'An outbreak of hepatitis associated with intravenous injection of Factor VIII concentrate', *The Lancet*, 2 August 1975; 221–223 [LIT.001.0360]

<sup>12</sup> Other clinical signs of infection included pyrexia and urticaria which had occasionally occurred with cryoprecipitate. The article commented that these signs did not occur with concentrates.

<sup>13</sup> Preston et al, 'Percutaneous liver biopsy and chronic liver disease in haemophiliacs', *The Lancet*, 19 September 1978; 592–594 [LIT.001.0387] Details are given in the Preliminary Report, paragraph 6.71. Professor Thomas identified this as Dr Triger's work: Day 52, page 1292.

<sup>14</sup> 'Post-transfusion hepatitis' *British Medical Journal*, 1981; 283 [LIT.001.0227]

<sup>15</sup> Stirling, Beckett and Percy-Robb, 'Liver function in Edinburgh haemophiliacs: a five year follow up', *Journal of Clinical Pathology* 1981; 34:17–20 [LIT.001.0748]

<sup>16</sup> Hay et al, 'Progressive liver disease in haemophilia: an understated problem?' *The Lancet*, 1985; 1:1495–98. [LIT.001.0335] In oral evidence (Day 8, page 4) Dr Hay noted that the article title was a 'poke' at another paper, published the previous year, which had suggested NANB Hepatitis might be an over-stated problem: Stevens et al, 'Liver disease in haemophiliacs: an overstated problem?', *British Journal of Haematology*, 1983; 55:649–655 [LIT.001.0008]

absence of objective clinical evidence before liver biopsy was widely practised, particularly on haemophilia patients. His evidence of what patients would have been told about the condition distinguishes him from others who continued to follow the MRC definition of hepatitis.

**34.19** Dr Hay said that in the mid- to late 1970s very little would have been said to patients about the risk of viral infection. From the late 1970s most regularly reviewed patients would have had liver function tests conducted and he expected that most of those affected would have been told that they had NANB Hepatitis, but that it was probably nothing to worry about.<sup>17</sup> His evidence about a diagnosis of NANB Hepatitis prior to 1983 is unlikely to have reflected universal practice, however, given the general adherence to the MRC definition of ‘hepatitis’, but the advice that NANB Hepatitis was probably nothing to worry about would have been consistent with the prevailing view, which continued into the mid-1980s. Professor Sherlock’s discussion of viral hepatitis in the 1981 edition of her standard textbook, *Diseases of the Liver and Biliary System*, indicated that the clinical course of NANB Hepatitis often involved a mild chronic hepatitis, but that the prognosis, while still uncertain, was probably benign.<sup>18</sup>

**34.20** In the mid-1980s it began to be recognised, first by hepatologists and some other specialists and later by the medical profession more generally, that infection with NANB Hepatitis could potentially be associated with more serious liver disease than had previously been thought. The risk of acquiring NANB Hepatitis had become the predominant concern in respect of the transmission of viral hepatitis following the transfusion of blood or blood products. The view of relative risk highlighted in the *World in Action* programmes had become more significant although, ironically, by that time the risk of transfusion-acquired Hepatitis B (the ‘hepatitis’ of the 1975 documentary) had become negligible.

**34.21** By the end of 1983, it was understood by haemophilia doctors that all factor concentrates, NHS or imported, carried a risk of transmission of NANB Hepatitis. Dr Craske’s 1982–1983 Annual Report for the UKHCDO’s Hepatitis Working Party, produced on 28 September 1983, noted that a prospective study begun in 1981 had confirmed that there was a near 100% risk of contracting NANB Hepatitis from Factor VIII concentrates on first exposure, whatever their source.<sup>19</sup> A report of that study, published on 10 December 1983, indicated that the diagnosis was based on elevated AST and ALT measurements and the absence of markers of other viral infections and clinical evidence of any other cause.<sup>20</sup> An editorial in the *BMJ* by Dr Jones noted that most post-transfusion hepatitis was now NANB.<sup>21</sup> However, he did not expressly link diagnosis to liver function test results, noting that abnormal results were found in most severely affected haemophilia patients who had repeated transfusions. There were conflicting views of the implications for patients of the changes in liver function then being observed. Dr Jones considered that most observed changes in liver function represented chronic persistent hepatitis rather than the more serious chronic active hepatitis.<sup>22</sup>

<sup>20</sup> Fletcher et al, ‘Non-A non-B hepatitis after transfusion of factor VIII in infrequently treated patients’, *British Medical Journal*, 1983; 287:1754–57 [LIT.001.0239]

<sup>21</sup> Jones, ‘Acquired immunodeficiency syndrome, hepatitis and haemophilia’, *British Medical Journal*, 1983; 287:1737-1738 [LIT.001.0243]; see Chapter 15, *Knowledge of Viral Hepatitis 2 – 1975 to 1985*, paragraph 15.127

<sup>22</sup> See Chapter 13, *Knowledge of Viral Hepatitis Now*, paragraph 13.43 for discussion of the difference between these two forms of hepatitis.

**34.22** Other elements were to enter the wider picture, as noted in Chapter 33, *An Investigation into the Systems in Place for Informing the Patients about the Risks – HIV/AIDS*. The 'Tarzanoid' approach to imported US concentrates in about 1983 described by Dr Winter, reflected patients' views that Factor VIII concentrate of ('good') British origin was to be preferred over ('bad') commercial products. Dr Winter thought that patients were fully aware that they risked contracting hepatitis if they used US concentrates, as exemplified in the 1975 television programmes.

**34.23** As the threat of AIDS came to be understood in and after 1983, the selection of products for therapeutic use became more problematical.<sup>23</sup> However, while the AIDS epidemic raised awareness of the risks of transmission of virus infection generally, it has to be borne in mind that understanding of the natural history of NANB Hepatitis had not matured. It is appropriate to consider in stages the provision of information and warnings to patients about NANB Hepatitis, as knowledge increased over this complex period. The first step is to examine what was said about viral hepatitis until 1983.

**34.24** As is apparent from the discussion of practice in the three major centres in the Royal Infirmary of Edinburgh (RIE), the Glasgow Royal Infirmary (GRI) and The Royal Hospital for Sick Children, Yorkhill, Glasgow (Yorkhill), that product selection varied considerably between 1975 and 1985 and the response of individual clinicians to the perceived risks, and communication of those risks, must be considered in that context.

**34.25** The data on product use accumulated by the UKHCDO has been set out in Chapter 21, *Haemophilia Therapy – Use of Blood Products*. In Scotland, with the exception of the two major regions centred around Glasgow and Edinburgh, there was little variation and, with the exception of a high use of FEIBA<sup>24</sup> in Aberdeen for particular patients, there was little use of commercial concentrates.

**34.26** The risk of transmission of NANB Hepatitis was related to the prevalence of infection in the donor population. As discussed in Chapter 3, *Statistics*, estimating that value from time to time was difficult and there are questions whether a reliable pattern was established. However, there are some acceptable indicators of the general picture:

- There was a statistically valid basis for estimating prevalence in September 1991.
- Prevalence of NANBH infection in the donor population was negligible in 1970.
- The introduction of self-deferral policies related to HIV/AIDS in 1984 is assumed to have had an immediate impact on prevalence in 1984 and a continuing impact from then until 1991.
- While calculating actual and estimated prevalence values remains problematical, it is likely that historic peak prevalence was reached in 1983, followed by a fall in 1984 and a gradual progression to September 1991 values thereafter.

**34.27** While none of this was, or could have been, known at the time, it appears that the risk of transmission of NANB Hepatitis was greatest for those treated first in the period up to 1983, fell significantly for those treated first in 1984 and grew gradually thereafter although by September 1991 it had not quite reached the estimated 1983 levels. The 100% prevalence of infection in haemophilia patients treated with concentrates found by Dr Craske at the end of 1983, coincides with the end of the period of highest exposure to

---

<sup>23</sup> See Chapter 15, *Knowledge of Viral Hepatitis 2, 1975 to 1985*, paragraphs 15.121–15.128

<sup>24</sup> FEIBA is a 'bypassing agent' used in the treatment of patients who develop inhibitors, or antibodies, to Factor VIII concentrates.

risk. The information and advice that could have been given in the 1970s and early 1980s would not have pitched the level of risk at or even close to 100%, until the studies were published and the results validated for the UK generally and for Scotland in particular. In 1980 and 1985 respectively there were 408 and 443 Haemophilia A patients registered with Scottish centres. The vast majority of those would have been exposed to the virus by the end of 1983.

## The evidence of patients and clinicians

### *Practice in Edinburgh and south east Scotland*

#### The evidence of patients treated in Edinburgh

**34.28** The witness given the pseudonym 'Mark' was treated in Edinburgh during the late 1970s and early 1980s and was introduced to home therapy in August 1981. Professor Christopher Ludlam wrote to Mark's local doctor on 13 August reporting his advice on the new treatment regime.<sup>25</sup> Mark recalled the risk of infection with hepatitis (and HTLV-III) being discussed at his clinic appointments, usually at the end of the appointment.<sup>26</sup> He described going down to England to stay with his grandparents and being given letters which he could hand over should he need to attend a hospital in England. The letters stated that he was to be treated with local Factor VIII only.<sup>27</sup> He told the Inquiry that he thought that there was more risk associated with commercial factor products<sup>28</sup> and that receiving only Factor VIII produced from voluntary Scottish donors was safer and carried less risk than the commercial products.<sup>29</sup> At Mark's regular clinic appointments blood samples would be taken and results from previous tests discussed. Mark knew that one of the tests was for hepatitis.<sup>30</sup> Although Mark believed that he was first made aware that he had Hepatitis C in 1997, his medical records disclose that, in December 1993, Professor Ludlam's clinical assistant had a long discussion with Mark about Hepatitis C after he was found to be antibody positive. The records also state that Mark was given an information leaflet about the virus and invited to attend a joint clinic.<sup>31</sup>

**34.29** 'James', the father of the witness given the pseudonym 'Frances', was aware of the risks of transmission of Hepatitis B when he was a patient of Dr Davies. In his case, Dr Davies agreed to experiment with early prophylactic treatment and recorded at the time, in April 1971, that the patient appreciated that there was a small risk of serum hepatitis from the transfusions.<sup>32</sup> At that stage, Hepatitis B was clearly the candidate virus. In a letter to the patient dated 9 July 1982, Professor Ludlam wrote:

Following our telephone conversation I enclose 2 letters. I hope they are satisfactory for your needs. I understand that you would like some factor VIII to take with you to [America]. If supplies permit we will try and let you have 40 bottles on [date]. Please could you phone in a day or two in advance to make arrangements to collect the factor VIII. If possible, whilst in [America] could you try and avoid the use of commercial factor VIII concentrates, as they may well give you hepatitis. I would suggest that you try and obtain cryoprecipitate for

<sup>25</sup> From medical records recovered in respect of witness Mark.

<sup>31</sup> Ibid paragraph 5.263

<sup>32</sup> Ibid.

minor bleeds. Obviously, if you have a major bleed, then you will have to take the advice of the local [hospital] staff at the haemophilia centre and possibly have commercial factor VIII.<sup>33</sup>

In 1988 James, who had already been diagnosed with HIV, was referred by Professor Ludlam to Dr Niall Finlayson, Consultant Physician at the Gastrointestinal and Liver Service at the Royal Infirmary of Edinburgh as he was mildly jaundiced and his liver was enlarged.<sup>34</sup> Dr Finlayson diagnosed James with chronic liver disease and thought that this was probably caused by chronic non-A non-B Hepatitis virus from blood products. James died in 1990.

**34.30** The witness given the pseudonym 'Elaine' told the Inquiry that her husband, Brian, was warned in general terms about the risk of a hepatitis virus.<sup>35</sup> As detailed in paragraph 5.235 of Chapter 5 it is likely that Brian was unaware before his death on 8 February 1992 (as a result of HIV) that he had acquired Hepatitis C. A blood test dated 13 January 1992 confirmed that he was positive for the virus. His wife, Elaine, did not find out her husband's diagnosis with Hepatitis C until 2002 when she went to her GP for testing after receiving information from the Haemophilia Society that patients who were HIV-positive were also very likely to be infected with Hepatitis C. She was concerned that she might have contracted the virus from her husband and have suffered, untreated, from the effects of it until 2002.

**34.31** The husband of witness 'Laura', who has Haemophilia A and who transmitted Hepatitis C to Laura, was a patient of Professor Ludlam.<sup>36</sup> In 1993, he received a letter from the Haemophilia Centre in Edinburgh advising him that he might have been infected with a virus. He then attended the hospital for tests and, at a follow-up appointment, was told that he had acquired Hepatitis C. Laura's husband could not recall what was discussed at these appointments. Laura was tested by her GP for the virus, at her own instigation.

### The evidence of clinicians: the use of blood products

**34.32** In Edinburgh and the south east of Scotland, practice until 1980 reflected the policies of the Director, Dr Howard Davies. He used SNBTS material, cryoprecipitate and concentrates, almost exclusively throughout his period as Director. The pattern changed with the appointment of Dr (later Professor) Ludlam. There was a dramatic increase in the use of therapeutic products generally in 1980, and for the first time in the region that included, in 1980 and 1981, a significant amount of commercial Factor VIII concentrate. Thereafter use of commercial concentrate was relatively low, but sustained, until the late 1980s when transmission of hepatitis infection had ceased to be a material issue.

**34.33** As Professor Ludlam understood the position, Dr Davies was very open with his patients about their situations. The patients he 'inherited' in 1980 had been looked after, as he put it, 'extremely well and obsessively'.<sup>37</sup> They were very well-informed.<sup>38</sup> Professor Ludlam said that there was a lot of discussion in Dr Davies' period about how many different sorts of hepatitis viruses there might be and that Dr Davies felt that it was better for patients, if they were going to get hepatitis, to get 'the local type of hepatitis'

<sup>38</sup> Ibid, page 11

because some of them might have immunity to it anyway having acquired the virus from the community, as happened with Hepatitis A for example.<sup>39</sup>

**34.34** Having regard only to the pattern of use, Dr Davies' period was stable. Professor Ludlam's change of practice suggests that in 1980 and 1981 there was a new focus for clinicians and patients, with the emergence of new treatments and the way in which they were used, which might have included a review of practice relating to the provision of information, advice and warnings relating to risk.

**34.35** From the record of products administered, Professor Ludlam's period in office began with fairly radical change. The use of SNBTS Factor VIII rose from 210,486 to 1,644,750 units. Use of cryoprecipitate rose from 694,190 to 1,212,470 units. In addition, 164,000 units of commercial product were administered. Over the next two or three years, most patients were put on home treatment with factor concentrates. By 1983 most patients with Haemophilia A registered with the Centre were being treated with SNBTS Factor VIII, though some received cryoprecipitate and some received commercial concentrates.<sup>40</sup>

**34.36** Cryoprecipitate was used where clinically possible to treat patients who had either never or only infrequently been treated with concentrates, particularly people with mild or moderate Haemophilia A who were unlikely to require frequent treatment. Commercial concentrates were used where clinically indicated. Haemophilia B patients were treated with SNBTS Factor IX concentrate.

#### The evidence of clinicians: information about the risk of infection with NANB Hepatitis/Hepatitis C

**34.37** Professor Ludlam provided the Inquiry with a statement on this topic.<sup>41</sup> In it he referred to a document entitled the 'Collective Response' of which he was one of the principal authors.<sup>42</sup> In his statement he said that the Collective Response reflected much of the practice in Edinburgh (and elsewhere).<sup>43</sup>

**34.38** The Collective Response was prepared by current and recent haemophilia clinicians to set out the history of haemophilia care in Scotland. Professor Gordon Lowe explained that there had been discussions amongst past and present haemophilia doctors in their regular meetings at the Central Legal Office. It had been suggested by the legal team representing haemophilia clinicians that such a document might be a useful supplement to the various individual witness statements produced for the Inquiry, especially as it could encompass the views of people with relevant knowledge who were unable, or not required, to give statements in their own right. The document was drafted mainly by Professors Lowe and Ludlam, with the assistance of Dr Brenda Gibson, the Director of Haemophilia Care at Yorkhill Hospital during the period dealt with in the Collective Response.<sup>44</sup>

**34.39** The Collective Response was written in sections. Professor Ludlam had already drafted a number of these as he had been involved in collating information over the years for various purposes. Around half of the completed document had been drafted by him from the perspective of the Edinburgh Haemophilia Centre.<sup>45</sup> Added to this was a section

<sup>39</sup> Ibid, page 10

<sup>44</sup> Professor Lowe – Day 80, pages 2–3

<sup>45</sup> Ibid, page 3

drafted by Professor Lowe and Dr Gibson giving their perspective on equivalent practices in the west of Scotland (GRI and Yorkhill). The entire document, as it then stood,<sup>46</sup> was sent to past and present Haemophilia Directors in Inverness, Dundee and Aberdeen to give them the opportunity to comment on its contents.<sup>47</sup> In the view of Professor Lowe, the revisions to the Collective Response at this stage were minor and there were 'relatively few changes' after he, Professor Ludlam and Dr Gibson had completed their drafts.<sup>48</sup> At the conclusion of the Collective Response there was a list of doctors and nurses who 'endorsed' its contents.<sup>49</sup> Professor Lowe ran through this list in oral evidence and gave a brief explanation of each individual's role.<sup>50</sup>

**34.40** While the Collective Response was well-intentioned, not much weight could be given to it as evidence. Whether there was a general practice in Scotland is a question for the Inquiry, and not for the haemophilia clinicians, or for a sub-group of them. As the evidence was to unfold, it became clear that there was considerable variation in practice. However, Professor Ludlam was entitled to adopt the statement as reflecting practice in Edinburgh. He clearly wrote much of the document on the basis of his personal experience.

**34.41** The Collective Response noted a problem that was common in Scotland and is accepted as accurate in this respect. Most patients with haemophilia who acquired NANB Hepatitis infection would have done so at the time of their first treatment with pooled factor concentrates or during their first several treatments with cryoprecipitate or fresh frozen plasma in the period following diagnosis. Many patients received their first treatment or treatments at a hospital that did not have a haemophilia centre.<sup>51</sup> In the south east of Scotland patients were treated at a number of district hospitals and in small hospitals in Edinburgh.<sup>52</sup> Local physicians may not have referred patients to haemophilia centres for many years and, when they did so, their referral letters would not usually state what information had been given to patients prior to their first treatment. In many cases, the information given in haemophilia centres would therefore have been given after the patient's first exposure to, and infection with, NANB Hepatitis/HCV.

**34.42** In Edinburgh, haemophilia care was provided by a multi-disciplinary team that, from 1982, included a Haemophilia Sister who played a major part in interacting with patients on a day-to-day basis, especially in the early 1980s when very many patients still had to attend hospital in Edinburgh for treatment of acute bleeds.<sup>53</sup> Professor Ludlam said:

It was our policy to inform patients (and parents of children) of all the risks of haemophilia as well as its treatment, including hepatitis because virtually all recipients of blood products were likely to be at risk or suffer from, this complication .... This would have included the complications of haemophilia itself and of its treatment. Discussion of hepatitis, like inhibitors, would be important topics. Information leaflets and contact with the Haemophilia Society was encouraged.<sup>54</sup>

<sup>46</sup> Professor Lowe thought that at this stage of drafting the contents of the Collective Response were divided equally between Edinburgh and Glasgow opinion; see Day 80, page 4

<sup>53</sup> Ibid [PEN.018.0832] at 0833

<sup>54</sup> Ibid [PEN.018.0832] at 0833–34

**34.43** The Collective Response stated:

The risks of haemophilia and of its treatment, including hepatitis, were well explained by staff and regularly reinforced by haemophilia nurse specialists and doctors.

....

Such education started when patients were first referred to a Haemophilia Centre, and continued thereafter, e.g. at emergency attendance for treatment of acute bleeding episodes, clinic reviews, and enquiries by telephone, in writing or in person.<sup>55</sup>

**34.44** From 1983 it was known that patients receiving clotting factor concentrates were at high risk of NANB Hepatitis infection.<sup>56</sup> The UKHCDO recommended the use of cryoprecipitate for patients with Factor VIII deficiencies and no, or limited, previous exposure to concentrates.<sup>57</sup> Professor Ludlam said that in the early 1980s he would have explained that he was administering cryoprecipitate to children to try to reduce the risk of contracting hepatitis, and avoiding the use of commercial concentrates because of the perceived increased risk of hepatitis in comparison to NHS concentrates.<sup>58</sup>

**34.45** Professor Ludlam said that it was well known amongst patients in the early 1980s that there was a risk of hepatitis from treatment with factor concentrates and cryoprecipitate. Like others, he observed that in the 1970s and 1980s there was literature available from the Haemophilia Society that commented on the risks. Patients on home treatment or their parents signed consent forms in which the risk of infection was specifically mentioned.<sup>59</sup> The consent form was, however, very general in its terms, referring only to 'the risk of an allergic reaction ... and ... the problems associated with any transfusion, such as the risk of introducing infection or air into my vein'.<sup>60</sup>

**34.46** Although Professor Ludlam said that he discussed the risk of hepatitis with some patients (if a patient became jaundiced then he discussed that with them and explained how it would have arisen, for example), he was unable to recall specifically whether or not he routinely discussed this issue with patients on an individual basis in the early 1980s.<sup>61</sup> While members of the multidisciplinary team may have implemented the general policy regarding the provision of information, it appears that Professor Ludlam himself would not have done so as a matter of course. He said that a lot of information provided to people with chronic disorders who are seen very frequently, is done on a 'need to know' basis as the need arises in their clinical care.<sup>62</sup> It seems that his practice was to give information as the occasion demanded, rather than as an aspect of programmed communication of information. He said that he probably would not himself have raised with his patients the topic of the different kinds of treatment that they could be prescribed, in the context of the emerging risk of NANB Hepatitis.<sup>63</sup>

<sup>62</sup> Day 35, pages 11–12

<sup>63</sup> Day 39, pages 21–22

**34.47** Professor Ludlam explained that when patients first attended the Haemophilia Centre – usually having been referred by another hospital – it could be a stressful time, with the parents of children trying to assimilate a great deal of new information while also dealing with an upset child. He commented that these circumstances would not be conducive to the parents remembering everything that they had been told at that first attendance. These sessions were therefore followed up at an early stage by giving patients, and their parents, booklets about haemophilia, including information about hepatitis.<sup>64</sup> Patients and their families were also encouraged to make contact with the Haemophilia Society.<sup>65</sup>

**34.48** The impression of a continuous educational process as described in the Collective Response, making use of every contact to provide information, was not sustained in oral evidence. Advice was given occasionally rather than universally, and the oral evidence of patients referred to above is consistent with Professor Ludlam’s description of his practice: information was provided as he thought the occasion demanded, rather than in a structured and regular manner and this appears to have continued throughout the 1980s and into the 1990s.

**34.49** Much of the circumstantial detail provided by Professor Ludlam supports this approach. Many of the patients had male relatives with haemophilia and they, or their parents, were aware of the risks of hepatitis from information circulating in the family. Severely affected boys on home treatment and their mothers were vaccinated against Hepatitis B and, when it became available in 1992, Hepatitis A. They were educated on the risk of hepatitis, and how to handle needle-stick injuries and blood spills. The patients had regular four-monthly liver function tests before a test for HCV became available.<sup>66</sup> The provision of information as the occasion demanded was clearly proportionate to need.

**34.50** Professor Ludlam told the Inquiry that, because he was so keen for Edinburgh patients not to be exposed to commercial concentrates if possible, he gave them a small card to carry when travelling which said: ‘this patient has only been treated with NHS concentrate. If possible please treat with cryoprecipitate or NHS concentrate’.<sup>67</sup> It was explained to them that the reason for this measure was to minimise their risk of contracting hepatitis from commercial concentrate. As it transpired, there was no material difference in the risk of acquiring NANB Hepatitis between UK public sector products and commercial US products, but this was not appreciated until the end of 1983. However, during 1982 and 1983, this ‘NHS concentrate only’ policy may have protected some NHS patients from acquiring HIV from commercial product.

**34.51** Both medical and nursing staff took precautions to prevent infection during treatment. They wore disposable gloves and carefully disposed of needles, syringes, intravenous lines and blood or blood product packs.<sup>68</sup> This was obvious to patients.

**34.52** Professor Ludlam said that his patients knew that he had an interest in using liver function tests to monitor the risk of hepatitis, and that test results would often be discussed with patients when they came back for review appointments.<sup>69</sup> He also commented that

<sup>69</sup> Day 35, page 9

some patients were generous enough to make themselves available for teaching students. Some patients were in the hospital quite frequently early in the reference period, because of the limited treatment that was available, and they often allowed him to bring medical students to see them. The doctors would have quite full discussions about the risks of treatment. He thought that his views would have been known to and accepted by the patients.<sup>70</sup>

**34.53** Professor Ludlam told the Inquiry that haemophilia patients in Edinburgh were kept up to date with developments during the 1980s when it came to be realised that NANB Hepatitis was more progressive than previously thought, and also later following the identification of HCV and the development of specific tests for the virus.<sup>71</sup> He said that patients and their families were aware of concerns about hepatitis because of frequent discussions at review clinics between clinicians and patients about the results of their liver function tests. He also thought patients were aware that the Haemophilia Centre was retaining blood samples for future virological testing.

**34.54** A few documents reflected this understanding. On 27 January 1986, Professor Ludlam wrote to patients enrolled at the Edinburgh centre.<sup>72</sup> The letter stated that Factor VIII and Factor IX might cause hepatitis in individuals with haemophilia ‘as you will know’, and was very occasionally transmitted to other members of the family. He wanted to investigate the position in local families. The letter noted that blood samples provided by family members were held in storage and asked patients to request the approval of the individuals in question for the use of these samples in the proposed study.

**34.55** Following the publication of a paper by Hoofnagle and others in 1986,<sup>73</sup> which established that Interferon could be successfully used to treat NANB Hepatitis, patients were informed of this development and studies were commenced to assess the use of Interferon.<sup>74</sup> As a result, from 1988 a few patients in Edinburgh with symptoms of NANB Hepatitis received treatment using Interferon.<sup>75</sup>

**34.56** From 1988 patients not previously exposed to concentrates were given information on virally-inactivated SNBTS concentrates and invited to participate in a clinical trial.<sup>76</sup>

**34.57** In the early 1990s an HCV patient information sheet and investigation check-list was developed for patients whose blood tests showed that they were HCV-positive.<sup>77</sup> The document, entitled ‘Hepatitis C Liver Disease and its Treatment’ stated that the patient’s blood results showed that they had HCV. It stated that the virus may cause inflammation of the liver, ‘known as hepatitis’, and that in some individuals the inflammation may become chronic, giving rise to long-term damage which may in some cases be severe. The document then set out the investigations required to determine the patient’s suitability for Interferon treatment and described the treatment and possible side-effects. It commented on the risk of sexual transmission and offered consultation to the sexual partners of infected individuals. It also contained advice on the use of alcohol.

<sup>77</sup> Patient information sheet [PEN.018.0807]

**34.58** Professor Ludlam said:

The information given to patients with non-A non-B hepatitis was continually updated with the developments in knowledge and practice. For example in the late 1970s and early 1980s it was a puzzling condition of uncertain aetiology but not known to be serious. At this stage there was no evidence that it might be sexually transmitted. It became clearer in the mid-1980s that it was a potentially serious and progressive condition although it has taken many further years of study to begin to obtain a reasonably reliable estimate of the risk of cirrhosis, liver failure and hepatoma development. Once it became clear that it was progressive and after Hoofnagle's paper in 1986, patients were informed of this and we consequently initiated studies to use interferon treatment.<sup>78</sup>

**34.59** The patient information sheet illustrated a further development in this approach.

**34.60** In general terms, Professor Ludlam thought there had been 'a very open policy of giving patients the most up to date information about hepatitis, their individual results and our assessment of their clinical situation'.<sup>79</sup>

**The evidence of clinicians: testing**

**34.61** Professor Ludlam explained that the Edinburgh Haemophilia Centre carried out 'anonymous' testing of stored samples when an HCV test became available. This was an early, insensitive test. The results revealed that 85% of those tested were HCV antibody-positive.<sup>80</sup> He published a small study of this group in a letter to *The Lancet* in September 1989.<sup>81</sup> Samples from 61 patients were tested: 48 had received non-heated factor concentrates before 1985 and 41 of these tested positive for anti-HCV. It is implicit in the report that the treatment histories of all 61 patients were known.

**34.62** Between 1990 and 1992 Professor Ludlam and colleagues assessed a series of different antibody detection methods. A paper submitted for publication in October 1991 reported a study of tests on stored sera from 85 randomly chosen haemophilia patients attending the Edinburgh Centre.<sup>82</sup> Of 78 patients previously exposed to non-virally-inactivated concentrates, 68 were confirmed positive by Chiron RIBA. Of the remaining 10, some were positive on some of the other tests applied. In addition, a virology colleague, Professor Simmonds, developed a polymerase chain reaction (PCR) assay to detect HCV viral RNA.<sup>83</sup> A study using this assay was carried out with 21 haemophilia patients and 27 intravenous drug users. From the results found and reported, Professor Ludlam said that it was clear that the first generation of the antibody test did not have sufficient sensitivity to 'identify all previously or currently HCV-infected individuals'.<sup>84</sup>

<sup>83</sup> Simmonds et al, 'Hepatitis C quantification and sequencing in blood products haemophiliacs, and drug users', *The Lancet*, 1990; 336:1439–72 [LIT.001.0287]

<sup>84</sup> Professor Ludlam's statement on Topic C5 [PEN.018.0832] at 0835

**34.63** By 1992 ‘reliable and sensitive’ assays for detection of the Hepatitis C antibody and virus were available. In his statement, Professor Ludlam said that ‘it was at this point that we felt confident to provide the results of these tests to patients’. It seems, therefore, that patients were tested for research purposes during the period 1989–92 but not given the results of the tests.<sup>85</sup>

**34.64** The process adopted for the first round of testing (in 1989) involved the selection of three sets of patients, grouped according to their treatment histories. The samples were labelled only according to these groupings and, when the results were received, the patients could not have been given their individual results. The use of an anonymous process was due, Professor Ludlam said, to his concerns about the reliability of the test.

**34.65** He explained that in 1992 in all cases, including cases in which stored samples had been tested during the initial studies to validate the techniques, a fresh sample was sought from the patient after ‘explanation and consent’:

The patients being told that we considered that we had a sensitive and specific test for both the antibody and virus which was responsible for the majority of cases of non-A non-B hepatitis. The result would be essential in deciding who might benefit from anti-viral therapy, e.g., it might be appropriate to offer therapy to PCR positive, rather than PCR negative, individuals. The patient would be given the result at the next clinic visit (or earlier if specifically requested). In most instances there was no need for the patient to receive the result urgently. The HCV tests were offered to all patients who we identified as having been exposed to blood or blood products.<sup>86</sup>

### **The evidence of clinicians: communicating test results to patients**

**34.66** Professor Ludlam stated that the information given to patients with non-A non-B Hepatitis was continually updated with the developments in knowledge and practice. He stated that once it became clear in the mid-1980s that the disease was progressive, patients were informed of this and studies were initiated on the use of Interferon treatment.<sup>87</sup> A Hepatitis C Patient Information sheet and an Investigation Checklist were developed in the early 1990s. Leaflets from the Haemophilia Society and the British Liver Trust were readily available in the Haemophilia Centre.<sup>88</sup>

### ***The practice at the Glasgow Royal Infirmary***

#### **The evidence of a patient who was treated in the Glasgow Royal Infirmary**

**34.67** David was treated with Factor IX in both Yorkhill and the GRI. He said he remembered Hepatitis A being mentioned to him during routine screening for this virus in 1984, but stated that he was not warned of the risk of infection with any other virus from his treatment for haemophilia.<sup>89</sup> His medical records showed that, in 1983 while he was being treated at Glasgow Royal Infirmary, David was found to have abnormal liver function test results. NANB Hepatitis was thought to be the cause of these results. David has no recollection of these test results being mentioned to him. David found out from Professor Lowe in 1991 that he had tested positive for the antibody to the Hepatitis C virus.<sup>90</sup> He

said that Professor Lowe did not tell him much about the severity of the virus, its health implications or the risk of secondary infection. Professor Lowe told him that they would continue to monitor his liver function at his routine haemophilia clinic appointments.

### The evidence of clinicians: the use of blood products and information about the risk of infection with NANB Hepatitis/Hepatitis C

**34.68** For most of the reference period, Professor Charles Forbes was the Haemophilia Director at the GRI and he was in control of policy and practice in the Haemophilia Centre. Professor Lowe joined the Infirmiry staff in November 1974. He was a Registrar and Senior Registrar from 1976 to 1985<sup>91</sup> and then Co-director of the Centre from 1988 to 2009.<sup>92</sup>

**34.69** Professor Forbes said that in the 1970s to early 1980s, when, as he remembered it, the usual policy for haemophilia bleeding was the use of pooled cryoprecipitate, clinicians were all aware of the potential problems associated with giving material of human blood origin to individuals. They monitored patients for changes in liver function, using what at that time were probably the best and only available tests.<sup>93</sup> Changes in liver enzymes were a good indicator of infection.<sup>94</sup>

**34.70** Professor Forbes said that it would have been very reasonable to have discussed with patients the risks of contracting hepatitis, and that would have been the Centre's policy at that time. He said that patients at the GRI Centre would certainly have been told that there was a possibility of hepatitis resulting from the use of concentrates or cryoprecipitate, and that they would be followed up after receiving blood products of any type. It is worth noting that in an article in the Haemophilia Society Bulletin 1 of 1980, Professor Forbes mentioned Hepatitis B as a 'serious side effect' of treatment with concentrates, but made no mention of NANB Hepatitis.<sup>95</sup>

**34.71** Professor Lowe gave both written and oral evidence to the Inquiry on this topic and was one of the principal authors of the Collective Response. He said that he had discussed his recollection of events for the purposes of that document with Professor Ludlam and Dr Gibson. He agreed that it was possible his recollection of events had been influenced by other people's recall of the same events but said that his own statement,<sup>96</sup> submitted as a separate document, reflected his personal experience and was probably a better reflection of his own recollection of events concerning NANB Hepatitis and HCV, than his contribution to the Collective Response.<sup>97</sup> That is clearly correct, and it is inappropriate generally to rely on the Collective Response in relation to practice at the GRI.

**34.72** One point already mentioned is material, however. The Collective Response emphasised that the problem arising from treatment of patients at local hospitals, before reference to haemophilia centres, was particularly significant in the west of Scotland.<sup>98</sup> In view of the territorial extent of the region, that clearly must have been the case.

<sup>91</sup> Professor Lowe, in oral evidence, corrected a typographical error in his statement. He was a 'trainee' doctor from 1976 to the end of 1985, and not 1987. He became a consultant in 1985. Prior to that he was a Registrar and then a Senior Registrar and medically qualified to treat patients. Day 80, page 15

<sup>92</sup> Professor Lowe's statement on Topic C5 [PEN.018.0839] at 0839

<sup>93</sup> As stated in paragraphs 21.313–21.320 of Chapter 21, *Haemophilia Therapy – Use of Blood Products*. Professor Forbes' recollection about the pattern of use of therapeutic materials did not accord with the UKHCDO statistics on the administration of blood products at the GRI.

<sup>94</sup> Professor Forbes' statement on information given to patients [PEN.012.0411]

<sup>96</sup> Professor Lowe's statement on Topic C5 [PEN.018.0839]

<sup>97</sup> Professor Lowe – Day 80, pages 9–10

<sup>98</sup> Collective Response on behalf of past and present Haemophilia Centre staff in Scotland on Topic C5 [PEN.018.0649] at 0650

**34.73** Professor Lowe told the Inquiry that, when he began working in the University Medical Unit at the GRI at the end of 1974, the first thing he noticed was big red signs labelled 'Hepatitis'. Every room in the Haemophilia Centre had such a sign. From his first day at the unit he observed that patients were being tested for Hepatitis B and that liver function tests were being carried out. There was an emphasis right from the start on reminding patients to be careful with needles and blood and on the disposal of all equipment.<sup>99</sup>

**34.74** Management of haemophilia in the mid-1970s included routine monitoring (usually annually at clinic reviews) for complications of the disease and of its treatment (including hepatitis). Routine blood tests included:

- Full blood count including haemoglobin, differential white cell count (an assessment of the different types of white cells) and platelet count.
- Assessment of blood chemistry including liver function tests – to assess possible presence and degree of hepatitis.
- Assessment of clotting factor function – for example, Factor VIII level and the presence of any Factor VIII inhibitor.
- Taking samples for virology, specifically for Hepatitis B antibody and antigen.<sup>100</sup>

**34.75** Professor Lowe recalled sitting in on haemophilia review clinics listening to the Consultants telling patients that they were going to take blood tests to check for hepatitis, which was a risk associated with blood product therapy. He said that the majority of patients who attended the Haemophilia Centre had been treated since childhood and knew what the tests were for and that none of it was a surprise to patients.<sup>101</sup> In addition, the Haemophilia Society issued a lot of booklets and pamphlets over the years which included information on the risks of hepatitis.<sup>102</sup>

**34.76** Professor Lowe gave evidence that haemophilia patients (and, in the case of children, their families) at the GRI were routinely advised by medical and nursing staff of the risk of infection by the blood-borne hepatitis viruses (HBV and NANB Hepatitis), both before and after their treatment with blood products. Furthermore, he thought that the risk of infection would have been apparent to patients from several of the routine practices at the GRI:

- Both medical and nursing staff took obvious precautions to prevent infection during treatment. They would wear disposable gloves and carefully dispose of needles, syringes, intravenous lines and blood or blood product packs.<sup>103</sup>
- Patients or their parents were provided with, or given access to, educational and information leaflets, such as those issued by the UK Haemophilia Society.<sup>104</sup> Professor Lowe considered that the Haemophilia Society was generally well-informed and was aware of the risks of hepatitis as knowledge developed. The Society issued regular

<sup>101</sup> Professor Lowe – Day 39, page 163. The patients at the Royal Infirmary were usually older children and adults who had previously been patients at Yorkhill during their earlier years.

<sup>102</sup> Professor Lowe – Day 39, page 164

<sup>103</sup> Professor Lowe's statement on Topic C5 [PEN.018.0839] at 0839

<sup>104</sup> Ibid [PEN.018.0839] at 0839

information leaflets and other publications to its members. It also produced other, more occasional, publications for patients and their relatives and these were displayed in the waiting area and treatment rooms of the Haemophilia Centre at the GRI.<sup>105</sup>

- Patients, or their parents, who requested further information about NHS or commercial clotting factor concentrates were given the information leaflets provided along with the concentrates themselves. These package inserts included details on the possibility that they might transmit hepatitis.<sup>106</sup>
- A vaccination against HBV was introduced in the UK in 1985 and was offered to patients who lacked natural immunity. Patients were told that the vaccination was protective against HBV only, and not against threats from other hepatitis viruses, such as NANB Hepatitis. Similar advice was given when the HAV vaccine was offered to patients from 1992. The parents of children with haemophilia were also offered vaccinations and advised on the risks of hepatitis from blood spills and needle-stick injuries.<sup>107</sup>
- A journal article published in 1983 made it clear that patients treated with clotting factor concentrates had a high risk of developing NANB Hepatitis.<sup>108</sup> As a result the UKHCDO recommended that cryoprecipitate be preferred to clotting factor concentrate for patients with mild haemophilia who had no, or limited previous exposure,<sup>109</sup> before 1988.<sup>110</sup>
- From 1988, patients who had not been previously treated with concentrates were given information on, and invited to participate in, a clinical trial of virally-inactivated SNBTS clotting factor concentrates, to demonstrate that it would not infect them with NANB Hepatitis.<sup>111</sup>
- When recombinant factor concentrates (artificially synthesised clotting factors free from the risk of transmission of viruses from blood donors) were licensed in the UK in 1995, haemophilia directors ensured they were made available for treatment of patients with haemophilia in Scotland. The first priority was patients not previously exposed to clotting factor concentrates.<sup>112</sup>

**34.77** Professor Lowe stated that it was considered important to regularly monitor liver function and keep patients abreast of changing information about the disease.<sup>113</sup> The message to patients at the GRI prior to 1985 about how concerned they should be about this condition was:

[W]e would say that, "Non-A non-B Hepatitis is a concern. We need to monitor you for it. We will explain what we are doing collectively to minimise the risks through safer products and immunisation, and regular medical review is important and it gives us a chance to continue to update you on the significance."<sup>114</sup>

**34.78** From 1985 it was known that the asymptomatic stage of NANB Hepatitis infection could progress to serious liver disease and this was communicated to patients or their parents at their clinic reviews.<sup>115</sup> Professor Lowe recalled that by this time every haemophilia centre in the UK was seeing one or two patients who had clear clinical evidence of liver disease. There was a hepatitis working group monitoring these studies and passing on reports to doctors and to the Haemophilia Society.

**34.79** The Haemophilia Centre at the GRI was amongst those seeing a small number of patients with clinical liver disease and all patients in receipt of blood products were being more closely monitored as a result. Previously, patients with cirrhosis seen in the haemophilia unit at the GRI had been those infected with Hepatitis B or who were heavy alcohol users; in 1987 the centre in which Professor Lowe worked saw its first patient with early cirrhosis caused by NANB Hepatitis.

**34.80** The message to patients at this point was similar to that given before 1985; but they were now advised that it appeared that a number of patients might progress to serious liver disease.<sup>116</sup> When talking to patients in his clinic, Professor Lowe found it helpful to give them a rough percentage of people who might expect to be affected. He stated that between 1985 and 1987 he would have advised all of his patients that those with NANB Hepatitis had a 25% risk<sup>117</sup> of progressing to cirrhosis as a result of their infection.<sup>118</sup>

**34.81** At routine clinic sessions, Professor Lowe would enquire about a patient's recent health and ask if they had noticed any change in their well-being. Any incidence of jaundice would naturally be of concern but Professor Lowe would also routinely carry out a physical examination of his patients' abdomens to feel the condition of their liver and spleen. Blood samples would be taken for liver function tests and, if the results from a previous test had been abnormal, he would discuss the likely cause of that abnormality with the patient at their next review. In the absence of any other explanation, he would advise that the most likely diagnosis was NANB Hepatitis, which he would then discuss with the patient. Professor Lowe also said that, even for patients with normal liver function test results, the state of knowledge of the severity of NANB Hepatitis, as understood at that time, would be communicated to everyone at clinic reviews.<sup>119</sup> From 1985 patients (or their parents) were also told that it was hoped that concentrates could be successfully virally inactivated in the future and that this would reduce or remove the risk of transmission of NANB Hepatitis.<sup>120</sup>

**34.82** Professor Lowe recalled that a few years later, around 1988–89, patients reviewed in his clinic were told the estimation of risk of cirrhosis following NANB Hepatitis infection had increased from 25% to 33%. He was of the view that his medical colleagues in the Haemophilia Unit at the GRI would be passing on the same information to patients.<sup>121</sup> There would be regular meetings within the haemophilia centre to ensure the clinicians and nurses<sup>122</sup> shared information, and were able to pass consistent advice to their

<sup>121</sup> Professor Lowe – Day 80, pages 31–32

<sup>122</sup> Ibid, page 48

patients.<sup>123</sup> It was helpful to the Centre that Dr Forbes, their Director, was at that time also the Chairman of the UKHCDO. Professor Lowe was asked what the Centre's policy about hepatitis was at this time. He explained that it was:

To tell patients about it and to explain ... that all patients should be asked about symptoms of liver disease, examined for liver disease, have blood tests taken for liver disease and to explain to them often at the time that you were discussing blood tests, you would say, "I want to check you out for Hepatitis B and non-A non-B, and the current situation with these problems in haemophiliacs in the United Kingdom is this, and this is why it's important that we do this", and, "Keep coming to the clinics and we will keep monitoring you for the complications".<sup>124</sup>

**34.83** Professor Lowe also recalled that it was around this time that the risk of progression to liver cancer in those with NANB Hepatitis was becoming clearer, and that this was also discussed with patients at review appointments:

Yes, I think it would be about that time that liver cancer was being reported, associated with Hepatitis C, in the early 1990s.

So we would talk about cirrhosis, what was cirrhosis and what would the symptoms be, and what would the prognosis be for somebody who developed cirrhosis and what treatment would be given, and then to say that particularly patients who have developed cirrhosis – the liver as part of a cirrhotic process, it's prone to forming tumours .... "We will carry on examining you, doing the blood tests, and we may start doing liver scans but .... Once we get the tests to see if you carry the virus or not, if you do carry the virus, we will then be referring you to [the] liver clinic for more detailed information from the liver doctors, the experts ...." As we had already done for HIV a few years previously.

We said, "We will continue to follow you up and give you whatever advice and support we can as haemophilia doctors and nurses, but it's time for the specialists to start taking over your liver disease and they will give you full information about the up-to-date prognosis, estimates and further tests, like genotype and scanning. And the good news is that we have antiviral treatment starting to be developed .... The hope is that it will work in some people with Hepatitis C."

"So again, this is part of a journey, where we are all learning about the virus, we are all learning about the tests, the prognosis and the treatment, and we will keep you informed as much as we can."<sup>125</sup>

**34.84** Professor Lowe stated that before the identification of HCV and the introduction of a specific test at the end of 1991, informed advice on the possible sexual transmission of NANB Hepatitis could not be given as not enough was known about the disease.<sup>126</sup> After that date, and as evidence of low rates of sexual transmission became clearer, the risk of sexual transmission of HCV was discussed with infected patients at their routine appointments at the GRI.<sup>127</sup>

---

<sup>126</sup> Professor Lowe's statement on Topic C5 [PEN.018.0839] at 0847

<sup>127</sup> Ibid [PEN.018.0839] at 0844

**34.85** In oral evidence, Professor Lowe agreed that the best method for a clinician to give information to a patient about treatment and prognosis was through direct, face-to-face communication. However, he noted research which had demonstrated that patients often do not take in all of the information they are given in an interview with their doctor or nurse and suggested that direct, face-to-face communication could be usefully supported by information leaflets.<sup>128</sup>

**34.86** Professor Lowe added that any full, written protocol for use by doctors in haemophilia reviews would have been difficult to formulate. It would have had to be ‘a pretty long-winded protocol and ... so general as to probably be counter productive’. He thought that the best way to cover the wide range of issues that arose in a haemophilia review appointment was to lead by example, with real patients, showing the range of subjects that might be covered, and how to interact with patients.<sup>129</sup>

### The evidence of clinicians: testing

**34.87** Professor Lowe could not recall if there were written policies or protocols relating to hepatitis testing in place at the Glasgow Haemophilia Centre in the 1970s and 1980s. He could, however, recall that the GRI produced written policies from around the 1990s, following the introduction of a specific screening test for HCV, which included HCV testing as part of liver function monitoring, along with vaccinations for Hepatitis A and B.<sup>130</sup> Following advice from the UKHCDO, from late 1991 the co-directors of the GRI Haemophilia Centre added HCV testing to routine surveillance for liver disease in haemophilia patients.<sup>131</sup> By then, second generation test kits of improved specificity and sensitivity were available from the Regional Virus Laboratory at Ruchill Hospital, Glasgow.

**34.88** In the period 1990–95, patients were asked to give fresh blood samples at their clinic appointments. Professor Lowe and his colleagues would explain that, in addition to the routine blood tests patients were aware of, there was now a test for the recently discovered Hepatitis C virus. He would add further that, now that the virus had been discovered, it was possible that anti-viral treatment might become available for the patients found to carry the virus.<sup>132</sup>

**34.89** Professor Lowe was asked to consider the report written for the Inquiry by Dr Hay. He considered that Dr Hay’s description of his practice as a haemophilia clinician dealing with patients with NANB Hepatitis/HCV infection was entirely in keeping with both his own practice in the GRI, and practice in haemophilia centres in Scotland, in the early 1990s generally. As he understood it, ‘practice was to inform patients about hepatitis C tests and outline what was known about HCV; and to inform the patient and their general practitioner of the results’. This had been the practice for HBV as knowledge about that condition increased and it was the opinion of haemophilia directors in the early 1990s that the practice should continue when dealing with patients with HCV.<sup>133</sup>

**34.90** Professor Lowe also agreed with Dr Hay’s view that there could be no useful comparison between procedures for HIV testing after 1985, and HCV testing in the 1990s, and expressed his disagreement with Professor Nathanson’s view (as he understood it when

<sup>132</sup> Professor Lowe – Day 80, pages 61–62

<sup>133</sup> Professor Lowe’s response to questions from the Inquiry about the reports of Dr Hay and Dr Nathanson [PEN.018.1240]

giving evidence) that ‘best practice’ HCV pre-test counselling was comparable to that considered appropriate for HIV testing.<sup>134</sup> He noted that, at a meeting of the Haemophilia Directors of Scotland and Northern Ireland on 6 February 1990,<sup>135</sup> it was reported that the UKHCDO and Haemophilia Centre Directors were advised by their medical defence societies that HCV testing could be undertaken on the same basis as other liver function tests, and that ‘HIV-type counselling’ was not necessary.<sup>136</sup> Professor Lowe also recalled that Dr Iain Simpson, Chief Executive of the Medical and Dental Defence Union of Scotland, had attended a meeting of the UK Regional Haemophilia Centre Directors. Professor Lowe said that when asked whether haemophilia clinicians had to go to the lengths of the HIV pre-test counselling prior to taking a blood sample for an HCV test, Dr Simpson’s opinion had been that ‘if patients are well used to being regularly monitored for post-transfusion hepatitis, and Hepatitis C is being added to all these other tests ... he could see no special case’.<sup>137</sup>

**34.91** Professor Lowe explained that he decided against giving HIV-style pre-test counselling to his patients in the early 1990s, because of the consensus that emerged after the lengthy discussions at the UKHCDO meetings, and because of Dr Simpson’s advice. Patients were not tested without their knowledge or consent, however. Professor Lowe stated that ‘we gave pre-test information about the test’, although the type of pre-test counselling thought suitable for HIV testing was not considered an appropriate model for the equivalent HCV test.<sup>138</sup>

**34.92** In his statement, Professor Lowe noted that patients were ‘routinely informed that HCV tests were being carried out’, although the Haemophilia Centre at the GRI did not call patients in especially to be told about the new HCV test. However, it was the practice there that every patient, even those very mildly affected, was seen at least annually for a review and more severely affected patients would typically have been seen earlier as they were reviewed more frequently. At review they would be told about the new HCV test once it had become available; they would then have been tested for the virus. Most patients were tested between late 1991 and late 1992.<sup>139</sup>

**34.93** He said that explanations were given before blood was taken.<sup>140</sup> Professor Lowe’s recollection was that, at the stage at which blood was to be taken, he would explain to his patients that a new test had become available for the most common cause of NANB Hepatitis:

“We are now coming to the routine blood tests and we would like to” – or we would want to – “this is now our policy,” at which point patients could say, “Well, I don’t want the test”. If they wanted. I can’t remember anybody saying no ... they already knew that they were being screened for non-A non-B hepatitis ....<sup>141</sup>

<sup>134</sup> Ibid [PEN.018.1240]

<sup>138</sup> Ibid, page 65

<sup>139</sup> Ibid, page 66

<sup>140</sup> Ibid, page 65

<sup>141</sup> Ibid, page 64

**34.94** Patients who had received pooled blood products would be told to be prepared for a positive test result, as research had shown the majority of these patients had been exposed to the virus. At that stage, although the test could establish whether the patient had been infected and had developed antibodies, it would not indicate if they still had the virus that could lead to chronic liver disease.<sup>142</sup>

**34.95** Professor Lowe went on to explain that, if a patient had a positive HCV test result, they would be sent notification of an early appointment for a clinic review, so that they would know within the following few weeks, or at most few months, about their test result and its implications.<sup>143</sup> The Centre would aim to see the patient for a half-hour appointment in a private room in the clinic to enable them to have a full discussion of the implications of a positive test result.<sup>144</sup>

**34.96** Professor Lowe explained what he would say to a patient who had received a positive HCV antibody test result. He noted that the information available to clinicians improved over time as more came to be understood about the disease. In 1991 he was only able to tell a patient that they had been exposed to HCV at some point, but not when. At that time, a doctor could not advise if having the antibody meant the patient was immune from HCV infection in the future. Most importantly he could not tell the patient if they were still carrying the virus and what the chances were of the virus causing future problems with the liver, although different tests were being developed in the hope of answering those questions. Professor Lowe would emphasise the importance for the patient of continuing to attend the clinic for regular reviews and monitoring. Even if the HCV test was negative, he would still advise his patient that the test would be repeated annually as there were concerns about the accuracy of the first-generation tests. Patients were advised to take the same precautions with regard to sexual intercourse and blood spills that had been recommended since 1985.<sup>145</sup>

**34.97** With regard to prognosis, if the later PCR tests demonstrated the patient was a carrier of the virus, they would have to be carefully monitored for liver disease and consideration of antiviral treatment.

**34.98** As knowledge of the risks of transmission improved, haemophilia patients at the GRI who tested positive for HCV were advised that, as the virus could in rare cases be transmitted sexually, they should use barrier contraception and discuss the risks with their partner who could be tested for HCV by their GP.

**34.99** Patients were also informed that treatment in the form of Interferon was being developed and becoming available, and that liver transplant was ultimately an option if required. Patients with a positive test result would also be referred to a liver clinic for monitoring of their HCV.<sup>146</sup>

**34.100** Professor Lowe was referred in oral testimony to the supplementary statement from Professor Nathanson discussed in Chapter 32, *An Investigation into the Systems In Place for Informing Patients about the Risks – Ethical Context*, and in particular her views on the correct approach to testing for HCV between 1991 and 2000.<sup>147</sup> He agreed that

<sup>146</sup> Professor Lowe's statement on Topic C5 [PEN.018.0839] at 0850-51

<sup>147</sup> Dr Nathanson's supplementary statement [PEN.018.0419] at 0421

Professor Nathanson appeared to be suggesting that, from 1997, best practice for HCV testing was to discuss the implications of the test and to give the patient time to consider whether to go ahead with it, as would happen with HIV pre-test counselling.

**34.101** He did not think that the timing and context of what Professor Nathanson told the Inquiry applied to what he was doing at his haemophilia centre in 1991, however. He had tested all his haemophilia patients before 1997. He disagreed with what Professor Nathanson told the Inquiry about appropriate practice in 1991, but by 1997 he agreed that the best practice was to give HIV-style counselling for HCV testing. He was asked why he thought a different approach was required in 1997:

I think one factor has been increasing knowledge of the severity of Hepatitis C. In 1991 we were keen to find out which patients had been exposed to it so that that could clarify advice given to patients and for management. It was hoped, I think, initially, that rather like Hepatitis B before it, the majority of patients would have cleared the virus and only a minority would then progress to liver disease. And I think the part of the change in opinion, which Dr Nathanson has considered, is that during the 1990s, we now know that only about a third at most of patients clear the Hepatitis C virus and two thirds are carrying it, and we also know that the proportion of patients developing serious liver disease is increasing. So I think there is a change in the perception of the severity in Hepatitis C.<sup>148</sup>

**34.102** Professor Lowe was then referred to the report written by Dr Charles Hay.<sup>149</sup> Professor Lowe noted the view of Dr Hay that there was no comparison between HIV pre-test counselling and HCV testing. He explained that hepatologists in Glasgow would not routinely give detailed counselling to patients when investigating them for liver disease: there could be a difference in approach between testing for HCV at the Haemophilia Centre and testing by a liver specialist. He thought that Dr Hay described a realistic approach in his report for the Inquiry, one that mirrored the practice at the Haemophilia Centre at the GRI at the material time.<sup>150</sup>

**34.103** Professor Lowe was asked to comment on some patients' and relatives' recollections that they were not told that they were being tested for HCV, and were not immediately told the results of their tests or the implications of the diagnosis. He was of the view that doctors and nurses did discuss hepatitis with their patients, particularly in the 1990s after testing for HCV became available. He identified several deficiencies in early knowledge about HCV which made it difficult to inform HCV-positive patients of the meaning of their diagnosis, including the long time lag until becoming ill, the uncertainty of the accuracy of early test results and the uncertainty whether those who tested positive might remain asymptomatic carriers of the disease. He noted that conversations with patients over the 1990s changed as more became known about the natural history of HCV, and it became apparent that it was considerably more serious than originally thought for some patients. He thought that patients may have been reassured by early conversations.<sup>151</sup>

<sup>148</sup> Professor Lowe – Day 80, page 87

<sup>149</sup> Dr Hay's report on communication to patients about hepatitis [PEN.018.0961] at 0991

<sup>150</sup> Professor Lowe – Day 80, page 90

<sup>151</sup> Ibid, pages 111-112

**34.104** He also commented briefly on studies that have established that many patients do not recall what they have been told in an interview with their doctor. His view was that the policy in the GRI was always to have very open discussions with patients and to be available to them for their questions. He thought that, overall, he and his colleagues did their best to communicate adequately with their patients and assumed they had achieved that goal.<sup>152</sup>

**34.105** Professor Lowe was referred to Professor Nathanson's suggestion that the way to deal with the phenomenon of some patients not absorbing bad news is to repeat the message and reinforce it at subsequent meetings. It was suggested to him that an explanation for the many patients who claimed not to have been given information was that this had not been done at the GRI. He was reluctant to accept that clinicians at the GRI may not have reinforced the details of the diagnosis at subsequent meetings with their patients. He was adamant that he and the Haemophilia Sister took significant steps to ensure that they were available for the patients to speak to and seek advice from.<sup>153</sup>

#### *Royal Hospital for Sick Children in Glasgow (Yorkhill)*

The evidence of parents of patients who were treated at Yorkhill Hospital, Glasgow

**34.106** Neither 'Christine' nor her husband were warned that their son, John, was at risk of infection with Hepatitis C from his treatment for haemophilia.<sup>154</sup> She was not warned that there was an increased risk from prophylactic treatment as opposed to treatment in response to bleeds. John was treated at Yorkhill Hospital until 1991 when his care was transferred to the Glasgow Royal Infirmary. The referral letter noted that John was positive for the antibody to the Hepatitis C virus.<sup>155</sup> According to Christine this result was not conveyed to either John or herself. She found out that John had Hepatitis C only after his death in March 1995, when she asked a nurse. The nurse replied 'Oh yes, all of our boys have got it'.<sup>156</sup>

**34.107** 'Alex' was first treated in 1986 when he was about six months old. Alex's father said that he remembered his son's first treatment very well. He recalled a doctor coming into the ward to see them and saying that they needed to treat Alex with Factor VIII as this was all they could do for haemophilia. At that time Alex's parents did not know what haemophilia was. The doctor told them that they would give Alex a dose of Factor VIII, and that Alex would probably need to take Factor VIII for the rest of his life.

**34.108** Alex's parents knew that the blood tests he underwent at each clinic appointment included a liver function test. At some point they were told that Alex was being tested for 'non-A non-B' but they did not know what that was.<sup>157</sup> They were not told the results of this test. Alex's mother was told that Alex had Hepatitis C in about 1993 at one of Alex's review appointments at Yorkhill Hospital. Alex's father stated that Alex's mother was not given any advice about the virus at that time. Neither of them knew then what Hepatitis C was.<sup>158</sup>

<sup>158</sup> Day 81, page 43

### The evidence of clinicians: the use of blood products and information about the risk of infection with NANB Hepatitis/Hepatitis C

**34.109** Dr Michael Willoughby was appointed Consultant Haematologist at Yorkhill Hospital in late 1973. He resigned in 1982 and took up an appointment in Australia. He was not traced by the Inquiry until October 2012, after the public hearings had concluded. He provided the Inquiry with two written reports.<sup>159</sup>

**34.110** Dr Willoughby's initial remit on joining Yorkhill was to set up a department able to carry out the haematology tests necessary to diagnose and manage blood disorders. His main focus in practice was on the management of childhood leukaemia.<sup>160</sup> Treatment of those conditions and related clinical trials were his main professional interests. Over the years he became increasingly involved with the clinical management of blood disorders, including haemophilia, but Dr Willoughby said that there was no question of him establishing a Haemophilia Centre at Yorkhill in his time there.<sup>161</sup> Children with all types of blood disorders from the west of Scotland were referred to Yorkhill.

**34.111** Dr Willoughby wrote a well-regarded textbook, *Paediatric Haematology*, published in 1977. Hereditary coagulation disorders and developments in their treatment up to the time of writing were discussed and set in the context of a busy haematology department caring for children with a wide range of illnesses.

**34.112** In relation to treatment of haemophilia Dr Willoughby received advice from Dr Forbes. In the late 1970s, he heard of the success of home therapy and decided to introduce it for patients attending at Yorkhill. Dr Willoughby used the commercial Factor VIII concentrate, Hemofil, for this purpose on the view that it was easier for the parents of children to use. It could be reconstituted more easily than other concentrates, was administered in low volumes and was injected using a slender scalp-vein intravenous needle.

**34.113** Dr Willoughby ordered the commercial concentrate through the hospital pharmacy. He considered the additional expense incurred over the use of SNBTS products to be justified for his young patients because of the advantages it offered in administration.<sup>162</sup>

**34.114** Dr Willoughby's narrative of his practice in introducing parents to home therapy dealt exclusively with the practical procedures involved. Parents were warned of possible reactions to Hemofil and were prescribed chlorphenamine for use if there were adverse, allergic-type reactions, although he could not remember that being a problem with Hemofil.<sup>163</sup> Cryoprecipitate was not suitable for home treatment of his patients because of the difficulties associated with its administration. He understood that all concentrates, whether SNBTS or commercial, carried a high risk of transmission of NANB Hepatitis. He commented on the introduction of home treatment:

I think it would be fair to say that in most patients their quality of life improved to an unrecognisable degree, with a number playing football at school. I personally thought it was proving one of the best things we had set up, and I think the others involved felt the same.

---

<sup>159</sup> Dr Willoughby's first statement on the use of blood product concentrates [PEN.019.1265]; Questions from the Inquiry to Dr Willoughby [PEN.019.1272]; Dr Willoughby's second statement [PEN.019.1272]

<sup>162</sup> Dr Willoughby's first statement on the use of blood product concentrates [PEN.019.1265] at 1266

<sup>163</sup> Dr Willoughby's second statement [PEN.019.1272] at 1274

We had no idea that we were exposing these patients to serious viral diseases. I believe that problem only started coming to light in around 1983, after I had left the U.K.<sup>164</sup>

**34.115** In relation to the risk of transmission of viral hepatitis, he agreed generally with his successor, Professor Ian Hann: NANB Hepatitis was not seen as outweighing the risk of serious bleeding. It was known that all concentrates, commercial and NHS, carried a very high, virtually total, risk of transmitting hepatitis but Dr Willoughby felt that the risk never justified giving up the use of concentrates.<sup>165</sup> The risk of transmission of Hepatitis B was well known, but thought to be in the past, and NANB Hepatitis was generally thought to be a less serious condition.

**34.116** Dr Willoughby left Scotland before the risk of transmission of HIV had become a reality and before the potentially serious consequences of NANB Hepatitis became apparent. His narrative of practice did not include the provision of information about the risk of transmission of viral hepatitis. It appears to be clear that he implemented the Yorkhill home treatment policy on the advice of Professor Forbes and found that it yielded the anticipated benefits in improving children's lives. With 'no idea'<sup>166</sup> that treatment was exposing patients to serious viral diseases, it also appears to be clear that he would not have discussed such an issue with the parents of his patients.

**34.117** Dr Anna Pettigrew, who worked with Dr Willoughby from 1980, had no recollection of discussing with Dr Willoughby the risks associated with treatment. They were aware of the risk of Hepatitis B but she thought that, probably until 1983, they were not really aware of any other risks; it was known that there was a possibility of another form of hepatitis that could affect haemophilia patients, '[b]ut the main concern at that time was Hepatitis B.' However, she thought that the benefits of treatment generally and home treatment in particular were quite obvious.<sup>167</sup>

**34.118** It appears that during Dr Willoughby's tenure there was not a systematic approach to providing information about the risks of transmission of viral hepatitis associated with therapeutic products at Yorkhill: there was no perception of a need for it at that time. As indicated by the scope of his textbook, Dr Willoughby was a paediatric haematologist, not a haemophilia specialist, and depended on Professor Forbes for advice on haemophilia.

**34.119** Professor Hann moved to Yorkhill at the beginning of 1983 and brought a fresh perspective to practice at the hospital. With experience of treating childhood leukaemia, he already had experience of dealing with patients, and parents of patients, confronting a potentially fatal disease. It appears to be clear that his decisions on therapy were influenced primarily by his response to the threat of AIDS and have been dealt with in that context.<sup>168</sup> He quickly abandoned the use of commercial products at Yorkhill, preferring cryoprecipitate or NHS Factor VIII concentrate. However, that decision does not appear on the evidence to have been prompted by a view relating to the risk of transmission of viral hepatitis. By the time NANB Hepatitis was recognised as a potentially serious disease, in late 1985, Professor Hann's practice was firmly based on the use of SNBTS products, using cryoprecipitate and Factor VIII as the situation demanded.

---

<sup>164</sup> Dr Willoughby's first statement on the use of blood product concentrates [PEN.019.1265] at 1267

<sup>165</sup> Dr Willoughby's second statement [PEN.019.1272] at 1274

<sup>166</sup> Dr Willoughby's first statement on the use of blood product concentrates [PEN.019.1265] at 1267

<sup>167</sup> Dr Pettigrew – Day 20, pages 19-20

<sup>168</sup> See Chapter 33, *An Investigation into the Systems in Place for Informing the Patients about the Risks – HIV/AIDS*, paragraphs 33.34–33.42

**34.120** Professor Brenda Gibson was appointed Paediatric Haematologist at Yorkhill in 1984 and became the Haemophilia Director there in 1988. She was the third principal author of the Collective Response. She also provided the Inquiry with a written statement.<sup>169</sup>

**34.121** Professor Gibson recalled that the parents of patients at Yorkhill would receive advice on the benefits and risks of treatment and were 'routinely informed of the risk of hepatitis (B and non-A, non-B)'. The risks of hepatitis would be explained by both medical staff and the haemophilia nurse specialist. Parents of children who administered factor concentrate at home were educated to take precautions to avoid transmission of infection and the risk of hepatitis.<sup>170</sup>

**34.122** Clinicians also relied on other sources of information from outside the hospital, such as that provided by the Haemophilia Society. The families of patients were encouraged to read the book *Living with Haemophilia* written by Dr Peter Jones, the Haemophilia Director in Newcastle-upon-Tyne, discussed above at paragraphs 34.9–34.13. Dr Gibson also referred in her statement to the large number of the mothers of Yorkhill patients who had male relatives with haemophilia and could gather information from them on the risks of hepatitis. Many of the families who attended Yorkhill with their sons would become friends and would share information.<sup>171</sup>

**34.123** Professor Gibson also noted that parents who administered factor concentrates to their children at home would be able to read the information leaflets provided in the box with the concentrates. This information would include the risk of possible transmission of hepatitis.<sup>172</sup> (See paragraphs 34.163–34.169 below for further discussion on SNBTS package inserts at this time.)

**34.124** From 1983 there was evidence that patients receiving factor concentrate had a high risk of developing NANB Hepatitis from initial exposure. As a result the UKHCDO, and others, recommended that 'boys who had never received clotting factor concentrate ... should receive cryoprecipitate in preference'.<sup>173</sup>

**34.125** Professor Gibson went on to add that the information from 1985 onwards about the increased severity of NANB Hepatitis came from studies of adult patients and, as a result, the significance of the virus for children was unclear. From 1985 onwards patients and their parents could be told that it was hoped viral inactivation of factor concentrates would be successful in reducing or eliminating the risk of transmission of NANB Hepatitis.<sup>174</sup> She went on to tell the Inquiry that children would have been the first beneficiaries of virally inactivated concentrate and that 'the advantages, primarily the reduction in risk of viral transmission, would have been explained to parents'.<sup>175</sup>

---

<sup>172</sup> Ibid [PEN.018.0824] at 0825. However note the comment of Dr Perry at paragraph 34.168 that the Product Information Leaflets were intended for prescribing doctors and not patients. It was not until 1994 that information leaflets for patients became mandatory

<sup>173</sup> Dr Gibson's statement on topic C5 [PEN.018.0824] at 0826: this appears to repeat the Collective Statement, but has been presented by Professor Gibson as her own evidence

<sup>174</sup> Ibid [PEN.018.0824] at 0827: this also appears to be an adoption of the Collective Statement

<sup>175</sup> Ibid [PEN.018.0824] at 0826

### The evidence of clinicians: testing and communication of test results

**34.126** In her statement Dr Gibson said that the testing for HCV in children with haemophilia took place in the same timeframe as the testing of adults, once antibody tests became routine in 1991. In the period from 1990 to 1995, blood samples were taken from all patients who had received blood products. She added that patients and their parents were routinely told that HCV testing was being carried out. Verbal consent was considered to be enough for hepatitis monitoring as it was considered to be a routine test.<sup>176</sup>

**34.127** If a patient proved to be HCV-positive, they and their parents were informed at their next scheduled clinic appointment, or at their next visit to the department. This gave patients and parents the opportunity to ask questions and discuss the significance of the test results. There was felt to be no immediate or urgent need to inform patients that they had tested positive.<sup>177</sup> The child's liver function test would be carefully monitored in future and they would be referred to a liver specialist for possible future treatment.<sup>178</sup>

**34.128** Patients were also given information leaflets about HCV from the Haemophilia Society and the British Liver Trust. Professor Gibson could not recall the Haematology Unit in Yorkhill having any of their own written guidelines or policies on communicating HCV test results to patients and parents. Where possible they adopted the UKHCCO guidelines.<sup>179</sup>

### *Ninewells Hospital, Dundee*

#### The evidence of a patient treated in Dundee

**34.129** 'Colin' received treatment for Haemophilia B on about six occasions prior to 1994, at Ninewells Hospital, Dundee. In 1995 Colin and his two brothers (who also suffer from haemophilia) were asked to attend Ninewells Hospital.<sup>180</sup> When they attended in August 1995 they were told that they should be tested for Hepatitis C. Colin's brothers were told in January 1996 that their blood test results were positive for this virus. As Colin had not heard the result of his own test he telephoned the hospital and was told in a short telephone call that if his brothers were positive for Hepatitis C, he would have it too. Colin and his wife then attended an appointment with Professor Cachia at which Hepatitis C and the implications of it were more fully discussed with him.<sup>181</sup>

The evidence of clinicians: the use of blood products and information about the risk of infection with NANB Hepatitis/Hepatitis C

**34.130** Professor Philip Cachia was a Consultant Haematologist at Ninewells Hospital, Dundee, from 1992. He had trained with Professor Arthur Bloom at the University Hospital of Wales in Cardiff.<sup>182</sup> He provided a written witness statement to the Inquiry and gave oral evidence about the dissemination of information about NANB Hepatitis/HCV at Ninewells Hospital.<sup>183</sup>

<sup>181</sup> Ibid paragraph 6.133

<sup>182</sup> Professor Cachia – Day 83, pages 8–11

<sup>183</sup> Witness statement of Professor Cachia [PEN.018.0853]; Day 83

**34.131** Professor Cachia explained that local practice in haemophilia care at Ninewells Hospital developed in three distinct phases:

- Before his appointment in 1992 there was no planned or managed process for discussing treatment or delivering ongoing care to patients with haemophilia. If counselling occurred it was on an essentially opportunistic, unstructured basis when patients were attending the hospital for other reasons.<sup>184</sup>
- From 1992 Professor Cachia was in post and in about 1993/1994 he took on the role of lead clinician for haemophilia care. He started to see patients and began to build relationships with them and deliver the required standards of care, although this still tended to be delivered on a somewhat opportunistic basis as he developed protocols and procedures over time.<sup>185</sup>
- A specialist nurse, June Ward, was appointed in January 1995 and helped to develop a formal appointment process. It was also around this time that a dedicated space for haemophilia care was found. Until that time a spare room in the day unit was used for interviews and delivering test results.<sup>186</sup>

#### The evidence of clinicians: testing

**34.132** When Professor Cachia arrived at Ninewells Hospital in 1992, he discovered during his initial assessment that HCV tests had been carried out by the virology laboratory on stored frozen blood samples and that there were around 25 haemophilia patients (of around 30 tested) who were HCV-positive.<sup>187</sup> Professor Cachia's predecessor in haematology had a list from the virology laboratory of the names of those patients who had tested positive for HCV.<sup>188</sup> It was not immediately clear to Professor Cachia if patient consent had been obtained for the tests to be conducted. The patients who tested positive had not been told of the results.<sup>189</sup>

**34.133** Professor Cachia discussed the matter with a consultant virologist at Ninewells who told him that the tests were performed on stored blood samples taken at previous appointments and that the tests had been performed 'more or less out of interest' when testing first became available, 'because they had the new assay'.<sup>190</sup> The consultant virologist was unable to tell Professor Cachia what patients had been told about why their samples were being taken and stored but was quite clear that, as far as he knew, consent had not been obtained prior to testing.<sup>191</sup>

**34.134** Professor Cachia said that he was 'horrified' to discover this. In the first instance, he said that he would not personally have sanctioned such testing without prior consent. Additionally, he was concerned that his first meetings with patients would require him to explain that they had been tested without their knowledge or consent, with some testing positive for HCV, and that this would be a poor start to the doctor-patient relationship. It was not something that he felt he could continue to withhold, however, and while telling patients what had happened would not necessarily be the very first thing he would say at their next review, 'clearly it would be a vital piece of information that I wouldn't withhold

<sup>191</sup> Ibid, page 26

from them'.<sup>192</sup> He therefore told patients that stored samples had been tested without their consent and asked for a fresh blood sample for further testing, after counselling the patients and obtaining their informed consent.<sup>193</sup>

**34.135** Shortly before moving to Ninewells, Professor Cachia had been involved in MRC research as part of his post-doctoral studies which had included obtaining 'informed consent' for participation in research projects. Asked what he took 'informed consent' to mean at that time around (1991–92) and in that context, he explained:

[T]he crucial issue is that the patient has a clear understanding, in language and terms that he or she can understand, of, in this case, the reason for undertaking research, the potential benefits to them and to future generations of doing that research, any potentially negative consequences of participating in the research and that they have control of that agenda and can get the information that they require and can then make a decision on a personal basis as to whether or not they wish to participate in that research.<sup>194</sup>

**34.136** Obtaining informed consent had to allow for variations in the understanding and comprehension of different patients:

[A] great deal of variation, and I think to really be able to obtain informed consent in that way, you need to firstly get to know and understand the patient. You need to develop trust as a mutual basis for the relationship, and once you have developed trust and know what their personal value systems are, what their intellectual capacity is, what their belief systems are, you can then have a real discussion that allows them to understand and, as I say, have control of the decisions that need to be made.<sup>195</sup>

**34.137** It appears from his subsequent evidence that this earlier experience in obtaining informed consent in a research setting had a significant bearing on, and informed, his practice when he became responsible for clinical haemophilia care at Ninewells Hospital.

**34.138** Professor Cachia told the Inquiry that the setting up of the Haemophilia Centre in Ninewells included establishing local protocols and guidelines for treatment and management of patients. He explained that the difference between a protocol and a guideline lay in the level of detail in each type of document and the purposes to which they would be put. A 'guideline' would be a regularly used document, perhaps printed, laminated and left in a ward for frequent consultation. A 'protocol' would be a more detailed document, not only setting out procedures to be followed but also providing a rationale for the advice, along with references to support it.<sup>196</sup>

**34.139** Professor Cachia was shown two documents and asked to comment on them in terms of this difference. The first,<sup>197</sup> although headed 'Protocol for monitoring patients with bleeding disorders and Hepatitis C infection', Professor Cachia described as a 'guideline' in terms of the distinction given above: it was a single sheet which could be kept on the ward as a 'helpful aide-memoire' for use in a busy clinic environment, a reminder as

<sup>197</sup> Protocol for monitoring patients with bleeding disorders and Hepatitis C infection, December 2005 [PEN.018.0930] provided to the Inquiry by Haemophilia Nurse Specialist June Ward with her statement [PEN.018.1225]

to whether a patient should have a particular test conducted based on their particular circumstances.<sup>198</sup> By contrast, a protocol would have a more educational purpose. It would not necessarily be for day-to-day use due to its level of detail, but could be consulted as a reference document.<sup>199</sup>

**34.140** The second document was Clinical Guidelines, dated 2008 and entitled 'Tayside Hepatitis C virus (HCV) managed clinical network'.<sup>200</sup> The document was not produced by the Haemophilia Centre at Ninewells. Professor Cachia described it as an NHS Tayside regional approach to providing care for individuals infected with HCV. Until the production of this document, which was focused on the treatment options, if clinicians wanted to offer Interferon therapy to a patient an individual case had to be made to the medical director through a hepatologist. This document was an attempt to standardise Hepatitis C treatment across all patient groups in Tayside on the basis of a protocol.<sup>201</sup>

**34.141** He did not develop a haemophilia patient protocol specifically for HCV testing. He worked on this area with Dr John Dillon, who was the principal source of expert advice around Hepatitis B and C, and utilised his patient treatment protocols for people with haemophilia.<sup>202</sup>

**34.142** From the point at which he took up his post in Dundee, Professor Cachia started to see haemophilia patients on a regular basis, including those who were not severely affected and might previously have attended the Centre only infrequently. As part of haemophilia care, he would monitor patients' general well-being, including the condition of their joints and their dental health, for example, but would also discuss health risks associated with treatment: the hepatitis viruses and HIV. His practice was to ascertain at an early stage what his patients knew about NANB Hepatitis/HCV and to build on that knowledge towards obtaining their informed consent for participation in ongoing reviews and assessments of their liver function and HCV status.<sup>203</sup>

**34.143** He said that he would take care to ensure that patients took in the information they were given. He would take time to assess his new patients and try to determine their level of understanding at the outset of discussion. Some patients would be well informed because of their membership of the Haemophilia Society, through other patients or through informal contact with medical and nursing staff.<sup>204</sup> If the patient had no prior understanding he would start from the beginning and explain the risks of viral hepatitis as a consequence of treatment with blood products and the importance of testing.<sup>205</sup> Whatever a patient's level of background knowledge, he would explain what was known of HCV and about the test and then ask the patient to tell him what they had understood of the discussion. If they could not give an accurate account he would know he had not succeeded in getting the message across.<sup>206</sup> Patients were not simply told that a test would be carried out: after discussion, a patient would have the opportunity to decline to be tested and those who had their blood tested would all have given their informed consent.<sup>207</sup>

<sup>205</sup> Ibid, page 38

<sup>206</sup> Ibid, page 48

<sup>207</sup> Ibid, page 38 and Witness statement of Professor Cachia [PEN.018.0853] at 0861

**34.144** He went on to explain what ‘obtaining consent’ in this context would have involved:

[I]t would have to be individualised and based on what they already knew. I would then take the conversation forwards and explain the latest information we had about Hepatitis C, about the Hepatitis C test, if they had or hadn’t been tested for it, and explain the potential benefits of that test.<sup>208</sup>

**34.145** In retrospect, Professor Cachia felt that perhaps he had given too much information to his patients at their initial appointments. Conscious that ‘there are limits to the amount we can assimilate, remember and truly understand’ he now feels that, in retrospect, ‘if I were doing it all over again, I might spread the load of information over two or three visits’.<sup>209</sup>

### The evidence of clinicians: communicating test results

**34.146** Professor Cachia was asked to describe practice at Ninewells in relation to communicating the results of a positive anti-HCV test, including whether patients were immediately told of their results. In relation to the early appointments (for patients previously tested without their knowledge or consent) described above, he said:

So for all of the patients, including those in whom we had been given the results from virology ... we took a fresh blood sample to confirm the test, and our aim was, in seeing a lot of these patients for the first time, to give them a follow-up appointment fairly rapidly, within a month or so, to discuss again the gamut of tests that we had undertaken. And if their HCV status was positive, we would take a second blood sample for a confirmatory test.<sup>210</sup>

**34.147** Professor Cachia explained that he would discuss the implications of a positive diagnosis with a patient, even before he had conducted the confirmatory test:

[P]articularly if, you know, if there was other supporting evidence. If it was a patient who had had extensive treatment, then they almost certainly were HCV-positive. If they had evidence of abnormal liver function tests or clinical evidence of chronic liver disease, then I wouldn’t necessarily wait for the confirmatory test.<sup>211</sup>

**34.148** He would tell patients about the implications of their diagnosis, which would depend in each case on the clinical context:

[I]f they very clearly had evidence of chronic liver disease, you would have to be honest and say that, you know, ‘There is evidence of progressive liver disease, so you may be in the group of patients who are going to go on and develop cirrhosis.’ If somebody had no evidence and over a period had relatively normal liver function tests, you would tell them that they might be in the better prognosis group but that there was no guarantee of this ... So you would try and stratify the risk according to all of the evidence in front of you and give them an idea of progression over time. So over successive clinic visits you would either try to reassure them or to be honest with them about the risk of progression.<sup>212</sup>

<sup>208</sup> Professor Cachia – Day 83, page 47

<sup>209</sup> Ibid, page 47

<sup>210</sup> Ibid, page 51

<sup>211</sup> Ibid, page 52

<sup>212</sup> Ibid, pages 52–53

**34.149** What patients were told about the disease changed between 1992 and 1995 as knowledge of HCV increased. In common with other witnesses, Professor Cachia said it was becoming clearer that the condition was not necessarily as benign as previously considered, for at least some patients.<sup>213</sup> He would advise patients that there was a recognised risk of progression to cirrhosis, but in oral testimony was unclear whether the possibility of liver cancer was discussed at this time, as it was not until later fully identified as a risk. Once the link was established it became part of the discussion with patients as it became increasingly important to closely monitor HCV-positive patients.<sup>214</sup> This was also the time when early treatment for HCV first became available; this, too, entered into the discussions he had with his patients and this part of the discussion itself changed considerably over time as treatment options expanded.

**34.150** Professor Cachia summarised the changing position at the time:

Knowledge of the complications and therapeutic options for HCV were continuously changing over the period from 1992. The approach taken ... was to have an open and frank discussion using non-technical terms to explain the nature of the infection and its origin, risks of spread including sexual intercourse (but not through normal social contact), the importance of monitoring clinical signs and blood tests, the potential benefits and risks of liver biopsy and treatment options as they evolved including Interferon, dual Interferon and Ribavirin and pegylated Interferon. Our aim was to enable patients to make informed decisions in relation to requesting approval for anti-viral therapy.<sup>215</sup>

**34.151** With regard to a patient's lifestyle, he would advise on alcohol intake as it can adversely impact on liver disease. They would also review prescription medication for potentially hepatotoxic effects (those adversely affecting the liver) and discuss over-the-counter medication.<sup>216</sup> He would remind patients of the risk of transmission to third parties and the precautions to be taken to minimise that risk. As evidence emerged of low incidences of sexual transmission, advice would be given on the use of barrier contraception and partners were offered HCV tests.

**34.152** Professor Cachia said that he did not approach the SNBTS around this time (mid-1990s) seeking advice on counselling patients with HCV.<sup>217</sup> He explained that the set-up in Dundee was unusual in that there was a regional transfusion service in the city that provided hospital blood banking. His team would have had a lot of contact with them with regard to blood for transfusion, and in relation to storage of factor concentrate, but not with regard to their working relationships with donors.<sup>218</sup>

### The evidence of Nurse June Ward

**34.153** When Professor Cachia became the Haemophilia Consultant at Ninewells in Dundee in 1992 he saw his patients alone. He did not have a dedicated haemophilia nurse until June Ward was recruited.<sup>219</sup> She was subsequently involved in counselling

<sup>219</sup> Ibid, page 36

haemophilia patients and assisting with testing, having received training from Professor Cachia. He said that they both believed in 'patient centred care' and had similar views about how the service for haemophilia patients should be developed.<sup>220</sup>

**34.154** Nurse Ward was employed as haemophilia nurse at Ninewells Hospital from January 1995. She provided the Inquiry with a short statement in response to two questions put to her about providing information on HCV, and communicating test results regarding HCV, to patients in the haemophilia ward from when she started in 1995.<sup>221</sup>

**34.155** She stated that there was a list of patients who had been identified as having a bleeding disorder and were HCV antibody positive. Those patients were prioritised and invited to attend the clinics at the haematology day area. They were offered further confirmatory testing, monitoring and treatment for HCV.<sup>222</sup> One of her roles from the beginning was to assist in the identification of patients who had been exposed to pooled plasma products and were at risk of HCV but had not yet been tested.

**34.156** There were no local (or indeed national) HCV guidelines or protocols in 1995. Nurse Ward told the Inquiry that the Haemophilia Centre at Ninewells followed the guidance provided by the *NHS Scotland Management Executive, Provision of Haemophilia treatment and care, MEL (1994) 29*, 23 December 1994. Over the next few years, the haemophilia service developed specific HCV protocols and Nurse Ward and Professor Cachia were involved in drawing up NHS Tayside HCV protocols, which have been reviewed and developed over the years to keep up with current knowledge.<sup>223</sup>

**34.157** Patients were invited to attend for review in relation to their bleeding disorder and, as part of their review, their HCV status was checked and discussed. In most cases Professor Cachia would take the lead at the consultation with Nurse Ward in attendance, but in his absence she would see patients by herself and advise them along similar lines. In this manner they ensured that all haemophilia patients were seen by an experienced and familiar member of staff. For patients not previously tested for HCV they would discuss with the patient the value of being tested and give them enough detail to enable them to make an informed choice. The patients identified as HCV-positive were offered a PCR test to confirm their illness.<sup>224</sup>

**34.158** She added in her statement that patients would be offered a combination of patient information booklets from the Liver Trust and the Haemophilia Society to back up the advice that they had been given verbally.<sup>225</sup> Test results were provided to the patient at an organised clinic within the haematology day area.

**34.159** In 1995 only Interferon was available for the treatment of HCV and none of their patients chose to take it up. Often patients' partners or family members attended these clinics and testing was offered where appropriate.<sup>226</sup>

***The evidence of patients or relatives of patients infected with Hepatitis C from blood transfusions or blood products***

**34.160** 'Bridie's' mother, Molly, was infected with Hepatitis C from a blood transfusion.<sup>227</sup> Molly received the blood transfusion due to very severe complications during the birth of her fourth child at a maternity hospital in 1974. In 1994 Molly was found to have cirrhosis of the liver during an unrelated surgical procedure. The circumstances surrounding her diagnosis with Hepatitis C are set out at paragraphs 6.77–6.82 of Chapter 6. Despite investigation of the cause of her cirrhosis by a consultant physician, it was not until Molly's GP tested her for Hepatitis C at the same time as he tested her liver function that she was diagnosed with the virus. That was in 1996. Molly's GP then wrote to Molly to inform her that she had tested positive for Hepatitis C. Molly's reaction to this news was that she had AIDS and was dying. Molly's GP referred her to a consultant physician who monitored her condition. She was referred to a consultant gastroenterologist in 1997. Molly's medical records show that she saw a nurse at this appointment who gave her written information about the virus and support groups.

**34.161** 'Gordon' acquired Hepatitis C from a blood transfusion after emergency and life-saving surgery in 1975. During the follow-up to this surgery Gordon was found to have abnormal liver function test results and in about 1978 he was told by the consultant physician reviewing him that NANB Hepatitis was the most likely cause of these results. Gordon continued to attend the hospital for monitoring until 1982. He moved to England in 1985. He was diagnosed with Hepatitis C in 1995 after being admitted to hospital for investigation of weight loss and exhaustion.

**34.162** 'Christine', who gave evidence mainly about her son John's infection with HIV, also gave evidence about her own infection with Hepatitis C from blood products. As detailed in paragraph 6.363 of Chapter 6, Christine was transfused with infected Factor VIII when she underwent elective surgery in 1981. She did not feel that she needed this treatment and asked for it to be stopped as soon as she became aware that she was receiving it. Christine found out from the SNBTS in 1991 that she had Hepatitis C. She donated blood and a couple of weeks after doing so received a letter from the SNBTS asking her to attend a meeting at their office. At that meeting she was asked if she had ever taken drugs, before it was suggested to her that she had been infected by the Factor VIII infusion. She did not recall receiving much information about the virus at that meeting. She was in shock. Afterwards she attended her GP who referred her to a liver specialist for treatment.

**Product inserts**

**34.163** Documents issued with SNBTS products contained information on risks associated with their use. These have been discussed generally in Chapter 33, *An Investigation into the Systems in Place for Informing the Patients about the Risks – HIV/AIDS*, paragraphs 33.75–33.92. The documents were described by Dr Robert Perry in an SNBTS document entitled 'Hepatitis Risk Warnings'.<sup>228</sup> Questions for Dr Perry were drafted by Messrs Thompsons. Dr Perry provided a witness statement responding to a list of eight questions.<sup>229</sup>

---

<sup>227</sup> Chapter 6, *The Effects of Infection with Hepatitis C, Including the effects of Treatment, on Patients and their Families*, paragraph 6.72

<sup>228</sup> *Hepatitis Risk Warnings*, SNBTS [PEN.012.0286]

<sup>229</sup> Dr Perry's statement in response to questions on SNBTS package inserts [PEN.018.0543]

**34.164** The fourth question posed for Dr Perry was: ‘Why was it considered appropriate to include a reference to the risk of hepatitis transmission in the PFC factor concentrate inserts’ over the period 1982 to 1985?

**34.165** Dr Perry said that the wording used in statements relating to the risk of transmission of hepatitis in PFC product leaflets was prescribed by the British Pharmacopoeia and approved by the UK licensing authority further to the PFC licence application in March 1978. Between 1978 and 1985 the description used in leaflets accompanying Factor VIII and Factor IX products which had not been heat-treated included reference to screening of donated blood for Hepatitis B surface antigen by specified tests, but continued: ‘Nevertheless none of these tests are of sufficient sensitivity to eliminate the possibility of transmitting hepatitis’. Similar warnings were given on vial labels, stating: ‘This preparation is of human origin and cannot be assumed to be free of hepatitis virus’.<sup>230</sup>

**34.166** Following the introduction of heat treatment of Factor VIII and Factor IX in 1985 the ‘warning statements’ in products’ leaflets changed. The package insert for Factor VIII now stated that the product could not be assumed to be non-infective. Factor IX was heat-treated differently, at a higher temperature, and its product leaflet stated: ‘The effect of this heat treatment on Hepatitis B and Hepatitis, non-A non-B has still to be elucidated and therefore, this product cannot be assumed to be non-infective with regard to the hepatitis viruses.’<sup>231</sup>

**34.167** Dr Perry said that prior to and during the period 1982–85, hepatitis transmission by coagulation factor concentrates was widely recognised and documented. Accordingly, all manufacturers were required by regulatory authorities to include hepatitis warning statements with their product packaging and information leaflets.<sup>232</sup>

**34.168** Dr Perry said that, as information leaflets were contained in the packaging of products supplied to patients for self-administration, patients on home treatment would have sight of such leaflets although they were not the primary intended recipients of the information prior to 1994. The information contained in package inserts at that time was detailed, technical and used specialist language.<sup>233</sup> They were designed for expert and experienced prescribers, in most cases haemophilia doctors. He did not think that such package inserts could be considered as providing relevant and material information for patients about the risk of transmission of viral hepatitis, including those patients on home treatment who might have had incidental sight of the information provided by the manufacturer.<sup>234</sup> Any discussion about treatment options and the risks involved was, he said, the responsibility of the doctor administering the treatment.

**34.169** For present purposes, therefore, the provision of information in the terms employed on SNBTS package inserts is irrelevant to the knowledge patients may have had about transfusion-associated transmission risk for the same reasons as are set out in Chapter 33, *An Investigation into the Systems in Place for Informing the Patients about the Risks – HIV/AIDS*. If the SNBTS had an obligation to inform patients using concentrates directly of the nature and extent of the risk of acquiring hepatitis infection, the package inserts and information leaflets would not have been sufficient for that purpose. However,

<sup>234</sup> Dr Perry's statement on package inserts and NANB Hepatitis [PEN.018.0556] at 0557

as the terms of the principal documents – the product licence applications – make clear, the procedure was regulated under the relevant Medicines Acts in force from time to time. In particular, the product constituents and specification had to be in accordance with the information contained in or supplied with the licence application. Hepatitis risk was identified as an aspect of the description of plasma. Until the regime changed in 1994 the SNBTS was not obliged to provide additional information to that prescribed.

### **The fallibility of memory**

**34.170** Before drawing conclusions – in particular on the practice in individual centres – it is appropriate to note evidence relating to the reliability of patients' recollections. It has been a common theme among the experts that patients often deny that they have received information or counselling and various reasons have been offered for that. It is understandable that stressful situations may affect the patient's ability to absorb information, and there may indeed be a reluctance to accept information about their condition and prognosis.

**34.171** The issue was focused in the evidence of the patient given the pseudonym 'Alex', and his father.<sup>235</sup> By the time of his first treatment for haemophilia in 1986, the potential seriousness of NANB Hepatitis was becoming known. Alex's parents found his first admission a traumatic experience. They had no experience of haemophilia. His mother was with him during this admission and she was provided with further information about haemophilia and was introduced to other parents of older children with the condition. The diagnosis caused his parents considerable and continuing stress, as was no doubt the case for many families in a similar position.

**34.172** These are not circumstances in which one could reasonably expect a clear and comprehensive account of what happened soon after the event. Twenty-five years later all of the factors apply that undermine the reliability of the evidence of those involved in or observing stressful events. Some positive elements will remain, but evidence of what did not happen or may not have happened is inherently less reliable. These are precisely the circumstances in which agreed and rigorously applied protocols are required to ensure that the patient is informed and that advice is also provided in written form that can be taken away and read and re-read as understanding of the condition grows. For treating clinicians, it is important that these events are recorded in patient case records at the time, to inform others co-operating in the patient's management both then and subsequently.

**34.173** However, there is no basis for assuming, or concluding on the evidence, that medical practitioners themselves generally have perfect recall. In relying on the fallibility of the patient's recollection of what happened, there is a danger that the doctor may be seen as simply serving his or her own interests in suppressing a similar failure of recollection. Comparison between statements in the Collective Response of what 'would have been' common practice in Scotland and the evidence of the clinicians who gave written and oral evidence to the Inquiry of their own approaches, is sufficient in itself to dispel any view that the recollection among medical practitioners was infallible. The position is relatively clear where the patient's medical records note that information or advice was given. Where that evidence is not available, a general assertion of what the witness recollects of common practice is not necessarily reliable. In such circumstances a practice protocol can provide not only guidance but can generate a document of record of what happened. That approach to record keeping was not adopted.

---

<sup>235</sup> See paragraphs 34.107–34.108 above

## Discussion and conclusions

### *Provision of information to patients*

**34.174** The evidence of practice from both patients and clinicians in the 1970s was that very little would have been said by haemophilia clinicians to their patients about the risk of infection with NANB Hepatitis. Dr Hay's evidence to that effect is accepted. The practice at the time was understandable against the background, firstly, of the widespread belief that NHS blood products (in particular Factor VIII concentrates) were less likely than imported commercial products to transmit viral hepatitis and, secondly, the understanding that NANB Hepatitis was a mild condition.

**34.175** As the 1970s progressed, and into the early 1980s, most patients had liver function tests. That raises a question as to whether a change in the approach to providing information and advice about NANB Hepatitis was appropriate. Dr Hay thought that from the late 1970s most patients having liver function tests would have been told that they had NANB Hepatitis. From 1978 at the latest, there was published information that there was at least the risk of transmission of NANB Hepatitis from the use of factor concentrates. Mr Watters' evidence about the discussion in Haemophilia Society Newsletters from 1978 illustrates that.

**34.176** It seems highly unlikely that asymptomatic patients would have been routinely advised of a relationship between the results of their liver function tests and the emerging risk of NANB Hepatitis, as long as overt clinical indications of hepatitis was a criterion for diagnosis.<sup>236</sup> The MRC definition of 'hepatitis', which included this criterion, was followed by most clinicians until at least the end of 1983 (when the article by Fletcher and others was published in the *BMJ*)<sup>237</sup> and by others until an anti-HCV assay was developed in 1989.

**34.177** The second factor of importance mentioned in paragraph 34.174 above (the understanding until late 1985 that NANB Hepatitis was a mild condition) meant that the risk of the virus was not thought to be serious enough to weigh in the balance against the need for treatment of coagulation disorders. When product selection first became a significant issue, it was in relation to the emerging knowledge of AIDS and the risk of transmission of an agent causing AIDS and AIDS-related diseases.

**34.178** In the circumstances, a uniform, invariable approach to the provision of information about NANB Hepatitis was not likely to be adopted by individual clinicians in the absence of authoritative advice from regulatory or advisory bodies or from the NHS. There was no advice until the late 1980s and none that was specific enough or relevant to HCV until the early 1990s.

**34.179** With the benefit of hindsight, it is clear that it would have been in the patients' interests for protocols to have been developed and applied in the 1980s, rather in the manner that Professor Cachia and the Tayside Health Board approached practice at Dundee in and after 1992. However, Professor Lowe was probably right in saying that it would have been impractical to prepare a protocol if one had to envisage a document that anticipated every individual patient's needs. Something rather less ambitious might

---

<sup>236</sup> The 1974 report of the UK Medical Research Council Working Party included in its definition of 'hepatitis' a finding of enzyme elevation in association with other clinical indications of hepatitis, typically jaundice.

<sup>237</sup> Fletcher et al, 'Non-A non-B hepatitis after transfusion of factor VIII in infrequently treated patients', *British Medical Journal*, 1983; 287:1754-57 [LIT.001.0239]

have sufficed if agreement could have been reached, however. It might have been practicable for the Scottish Haemophilia Directors to have promulgated a protocol that prescribed, for example, that what was known about NANB Hepatitis should be discussed from time to time with patients at risk, and as significant developments in knowledge occurred but without specifying the precise contents of the discussion or restricting the individual clinician's independence of judgement as to what was significant. No attempt to formulate a common approach was drawn to the attention of the Inquiry, however, and it is necessary to note individual practitioners' approaches and make such comment as seems appropriate.

**34.180** Patients receiving coagulation therapy using PFC products were exposed to the risks of transmission of NANB Hepatitis, up to October 1985 in the case of Factor IX, and April 1987 in the case of Factor VIII. For the vast majority of patients receiving concentrate therapy up to those dates, advice on the real risk associated with NANB Hepatitis came too late: almost all had been exposed to the virus. Depending on their individual genetic characteristics, patients in treatment had not been infected, had been infected but had cleared the virus spontaneously, were carriers of the virus but remained and were likely to remain asymptomatic, or were at some stage in the progression towards serious liver disease. In view of the long natural history of HCV, some people in the final group would not survive (dying of unrelated causes) to develop symptomatic disease.

**34.181** Whether a diagnosis of NANB Hepatitis would have been made depended on the position adopted by the clinician. Certainly until the end of 1983, those clinicians who applied the MRC definition of 'hepatitis' would have required clinical manifestations in addition to a finding of enzyme elevation. In the case of the Royal Infirmary of Edinburgh, Professor Peter Hayes' view was that few diagnoses of NANB Hepatitis would have been made. In their letter to *The Lancet* dated June 1987, Dr Dow and others commented that they had found reports in the west of Scotland of only 23 NANB Hepatitis cases in the previous eight years.<sup>238</sup>

**34.182** In Professor Hayes' experience of working in a large liver clinic, before HCV was discovered patients who presented with abnormal liver function test results were not usually diagnosed as suffering from NANB Hepatitis. There were many non-viral causes of abnormal liver tests. He said:

So a diagnosis of non-A non-B wasn't really considered in patients where an alternative explanation could be found and it tended to be triggered – or it's likely that it would have been triggered if somebody had had a blood transfusion and then had abnormal liver tests .... So if somebody just had abnormal liver function tests, it's relatively unlikely that a putative viral diagnosis would be made, but on the other hand, if somebody had had abnormal liver function tests following a blood transfusion, then that's more likely. But my understanding is it was not a very common diagnosis.<sup>239</sup>

**34.183** Until September 1983 the information that a haemophilia clinician would have been expected to give to patients about the risks of hepatitis infection associated with factor concentrates would have been that NHS products were safer and that, so far as there was a risk of infection, the disease was probably benign. In contrast, haemophilia

---

<sup>238</sup> Dow, Mitchell, Follett, 'Non-A, non-B Hepatitis surrogate testing of blood donations', *The Lancet*, 13 June 1987; 1366 [LIT.001.0346]

<sup>239</sup> Professor Hayes – Day 78, pages 46–47

was in fact associated with the risk of progression to serious and debilitating illness and possible death from haemorrhage. From September 1983, the NHS product would not have been thought less likely to transmit infection, but the perceived 'benign' prognosis for NANB Hepatitis would have remained the same until 1986 or 1987.

**34.184** It appears that from about 1980 at the latest there was widespread knowledge amongst patients and their parents that the use of factor concentrates was associated with the risk of developing hepatitis. Up to 1983 some patients in Scotland were expressly advised that the use of factor concentrates carried a fairly high risk of contracting viral hepatitis. Although some patients may not have been expressly so advised, it appears very likely that by 1983 all adult patients and parents of patients would have come to know, directly or indirectly, about the risk as understood at the time. What is less clear is whether, even by 1983, patients were being told explicitly of the risk of NANB Hepatitis as distinct from Hepatitis B.

**34.185** While in general terms the likely risks of 'hepatitis' from factor concentrate treatment were probably appreciated to a greater or lesser extent by most patients, what these risks truly were must have been less understood. Until 1985, no practitioner could have discussed the natural history of NANB Hepatitis infection in a fully informed way: the information was not available, and only began to be developed thereafter. No discussion of the risk of long-term progression to serious liver disease was likely to have taken place because no such risk was recognised. Any advice would have reflected the current understanding and that would not have reflected the reality of risk.

**34.186** It is questionable whether, apart from previously untreated patients and those who had previously received very little treatment, discussion would have been of practical assistance to patients. The critical time frame for advice relates to the point at which the diagnosis of a coagulation disorder was made and an initial decision on treatment had to be taken. Once the patient was on an established course of concentrate therapy, the risk of transmission of NANB Hepatitis/HCV crystallised and, at least until new information of relevance to the treatment regime or some other material change of circumstances emerged, the opportunity to give relevant and meaningful information about treatment (as distinct from the consequences of infection) was likely to have passed.

**34.187** In any event, even if some doctors, like Dr Willoughby, did not expressly advise their patients or patients' parents of the risk because at that stage they perceived that the risk of serious liver disease was negligible, Dr Nathanson's evidence was that she would not be critical of them on the basis of contemporaneous standards. In the 1970s and early 1980s medicine was more paternalistic and it was not unusual for doctors effectively to take decisions for their patients without discussing the balance of risks and benefits with them.

### Edinburgh

**34.188** Professor Ludlam's evidence that patients were informed about the risk of transmission of viral hepatitis from time to time as knowledge increased, is accepted on the basis that he described. It was done as circumstances required in the exercise of his professional judgement rather than as a matter of routine followed with all patients. There is reliable evidence that he did give explanations to some patients and those explanations appear to have been adequate, given the information in the public domain and available to clinicians at the time. Professor Ludlam's evidence was consistent with the evidence given by the patient witnesses in this respect.

**34.189** Professor Ludlam's practice throughout this period reflected his view that as far as possible his patients should be treated exclusively with NHS products. The slips issued to those travelling away from Edinburgh and the explanations given to patients would have left no room for doubt that his advice was that they should avoid commercial products because they carried a risk of transmission of viral hepatitis.

**34.190** That was one example of the application of his view that much information provision to people with chronic disorders who are being seen very frequently is done on a 'need to know basis' as it arises in their clinical care. Another example was discussion of the cause of jaundice, when it occurred in one of his patients that called for an explanation of how it could have arisen. On the other hand, he did not inform patients generally or systematically of the risk of transmission of NANB Hepatitis. He said that he would not have raised with his patients the topic of the different kinds of treatment that they could receive in the context of the emerging risk of NANB Hepatitis.

**34.191** Those of his patients who attended the local Haemophilia Society patients' group would have benefited from talks, by Professor Ludlam among others. Professor Ludlam provided leaflets and other Haemophilia Society publications. While it would not be appropriate for a clinician to rely on these as a substitute for giving information and advice directly, the general level of knowledge gathered from such sources, and from other casual sources such as media comment, would be matters to which a clinician would have regard. In particular it was appropriate to rely generally on the Haemophilia Society publications to supplement direct information and advice.

**34.192** Without adequate records generally, it is not possible to form a firm view that patients were fully informed of the risks associated with the therapy that they received. Having regard to the expert evidence of Professor Nathanson and Dr Hay about patients' abilities to absorb information, and thereafter to remember what they have been told, there was at all times a risk that information was not effectively communicated to or retained by patients. Whether from fear of confronting the implications of infection, or from an over-optimistic view of risk, built up over years of reassurance, or from a well-founded assessment of relative risk of bleeding and slowly progressing hepatitis, patients may not have understood the reality of their position. Practice now would be different, as Professor Ludlam accepted, but it is clear that from the earliest period patients accepted, and were expected to accept, that 'doctor knows best' and that was reflected in clinicians' practice in giving information and advice. Until the late 1980s, however, by which time viral inactivation had eradicated the risk of transmission of the putative NANB Hepatitis virus or viruses, there was no commonly accepted ethical principle or rule that would have been infringed by Professor Ludlam's treatment practice.

### **Glasgow Royal Infirmary**

**34.193** Professor Lowe's evidence is accepted that, throughout his period at the GRI, clinicians discussed 'hepatitis' with patients. Having regard to Professor Lowe's evidence, many patients attending the GRI throughout this period were informed of the risks of transmission of viral hepatitis associated with factor concentrate therapy, so far as it was understood. Review clinic practice appears to have been well adapted to provide opportunities for discussion and the provision of relevant information.

**34.194** The position with regard to providing information to patients about the specific risk of NANB Hepatitis is less clear. While Professor Lowe gave evidence of patients being advised prior to 1985 that NANB Hepatitis was a concern, and thereafter of the risk of developing serious liver disease, David recalled being warned only about the risk of Hepatitis A before being diagnosed with Hepatitis C in 1991. David was found to have abnormal liver function test results in 1983 and it was noted in his medical records that the likely cause of these was NANB Hepatitis. David did not recall being told of these results. There may be a number of explanations for this difference between the evidence of Professor Lowe and of David and, having not explored the matter in detail in evidence; it would be conjecture for the Inquiry to choose one. Whatever the explanation, David's evidence casts some doubt on the view that the risk of infection with NANB Hepatitis and the implications of the virus were consistently conveyed to all patients in the manner and detail stated by Professor Lowe.

**34.195** Practice varied across Scotland, not only as among haemophilia clinics, but within any particular clinic as among patients. Although general information about hepatitis was produced by bodies such as the Haemophilia Society, it could not be found that there were well-established and generally accepted procedural protocols (either written or understood and shared by practitioners) for communicating information to each individual patient about the risks associated with the use of therapeutic products, the relative risks of avoiding therapy, and the nature of the choice that the patient had to make about their own condition and treatment for it. Indeed, for much of this period the choice as to treatment was made for most patients in Glasgow, the same way it was made in Edinburgh.

### Yorkhill

**34.196** Christine's evidence of her experience at Yorkhill is consistent with the impression given by Dr Willoughby of practice during his period at Yorkhill. According to his written evidence he did not discuss the risk of transmission of viral hepatitis with children's parents. It appears that all major developments in the treatment regime applicable to Christine's son took place before 1983, when ethical practice would not have required discussion of such risks of transmission of NANB Hepatitis as were known to exist.

**34.197** Practice changed when Professor Hann succeeded Dr Willoughby in 1983. Professor Hann's evidence was instructive. New to Yorkhill, and entering a new specialist practice at a critical time, he faced the uncertainty of the aetiology of AIDS and its association with therapeutic blood products, yet had to communicate his position to parents of young children concerned about risk. He was also on course to change radically the regime of his predecessor and give up the use of commercial concentrates. He had a particular need to formulate his views. He had a clear preference for cryoprecipitate and otherwise preferred SNBTS concentrates. Of importance is his evidence of advising new patients' parents: the advice focused on the need for treatment, warning of side effects, but ultimately the choice was between cryoprecipitate and SNBTS Factor VIII. Not treating the child was not an option.

**34.198** Why Alex's parents may have been given insufficient information about the tests he underwent and about Hepatitis C generally can only, at this distance in time, be speculated upon. Equally, with whom responsibility for any such deficits lies can no longer be reliably ascertained. What can be said is that they found their experience in this respect to be unsatisfactory which underlines, should any underlining be required, the necessity for information to be provided to patients or, in the case of children, their parents.

**34.199** There is insufficient evidence in relation to the practice at Yorkhill to establish that, during the period in question, there was any breach of any principle or rule of ethical practice in force at the material time.

### Dundee

**34.200** In general, there is no evidence that haemophilia patients in Dundee had been told about the risk of NANB Hepatitis before Professor Cachia was appointed. Professor Cachia's evidence about the provision of information to patients was understandably limited by the fact that he did not start working at Ninewells Hospital until 1992. Professor Cachia's evidence was that until 1992 there was no planned or managed process for discussing treatment with or delivering ongoing care to haemophilia patients. Equally, counselling was then delivered on an opportunistic, unstructured basis. He sought to change and improve those practices including by discussing any health risks associated with treatment and devoting time to ensure that his patients understood any information provided by him. From the evidence available to the Inquiry, it appears that he and his colleagues succeeded in making significant improvements to the service in Tayside.

### *Testing and communication of test results*

**34.201** Routine blood tests in the course of management of coagulation disorder patients as described in this chapter do not raise any issue of ethical practice. Questions arise only where particular practices may have gone beyond the limits of implied consent and fallen into a category requiring specific or express consent from the patient.

### Edinburgh

**34.202** In one respect, there is a question whether practice at the Edinburgh centre fell short of what was acceptable. Professor Ludlam instructed testing for anti-HCV of stored samples from 61 patients in 1989 and the study was reported in a letter to *The Lancet* in September 1989. The patients were unaware that their blood samples were being tested in this way. The testing and the published material were anonymous: no reader could have identified the patients. Forty-one patients tested positive for anti-HCV. In 1991 samples from 85 patients were tested and these tests were confirmed by further testing in Dr Simmond's laboratory. The 1989 tests must have been carried out using first generation assays. Patients were not informed of the results of any tests until 1992 when fresh samples were sought for confirmatory testing. Many patients were unhappy that data about themselves had been published when they were unaware even that they had been subject to the tests.

**34.203** In 1988 the BMA guidance *Philosophy and Practice of Medical Ethics* had published the view that a patient should give consent before any investigation and treatment proposed by the doctor. (See Chapter 32, *An Investigation into the Systems in Place for Informing Patients about the Risks – Ethical Context*, paragraphs 32.43–33.44.) The publication of the results of the tests is not relevant: the data were anonymous. There are, however, issues as to whether testing the patients without informing them and obtaining consent to the study was contrary to the BMA guidance and whether there was an unacceptable delay in communicating the results. Dr Hay explained that at that time many practitioners did carry out testing on stored samples without consent. In addition, both he and Professor Nathanson explained that, in the context of patients who have already given consent to monitoring of liver function tests (LFTs), an anti-HCV test could be seen as an extension of that process.

**34.204** It was Professor Ludlam's stated view that he had explained to his patients that there was a risk of contracting NANB Hepatitis from the use of concentrates and that his patients had given consent to have their LFTs monitored for signs of that disease. It was probably implicit in that consent that new biometric tests for NANB Hepatitis viruses would be employed as they became available. Testing was routine over a long period and it was clear from the evidence of the witness Mark that he was frequently offered information about the test data recovered in his case. However, HCV was a newly discovered virus and was unknown when consent to monitoring LFTs had been obtained. It might be suggested that, by 1989, it was for the patients to decide whether the deficiencies in the accuracy of the test were acceptable before their samples were subjected to it and that specific consent should have been obtained. However, expert opinion did not support such criticism, particularly as the samples were anonymised before they were tested and no patient-specific results were therefore available.

**34.205** In relation to the second exercise in testing, which formed the basis of the 1991 paper, it is evident that this was conducted on named samples and therefore yielded results which could have been communicated to patients. It appears that the approach to communication of these results was not proactive: patients were instead offered a further test, with the appropriate explanation and consent, and then given the result of that at their next clinic visit. Inevitably, that meant there was a delay between the obtaining of the result for an individual patient in the course of the study, and the communication to that patient of the result of the further test.

**34.206** In these circumstances, while it is inappropriate to be critical of Professor Ludlam's approach to testing stored samples in 1989 and 1991 without permission, once the results became available they should have been communicated to patients within a reasonable time. The information belonged to the patients and should not have been withheld. For any one individual, it will be a question of whether the time taken for them to learn their HCV positive status was reasonable.

**34.207** With regard to the witness Elaine and her belief that her husband was not told of his diagnosis with HCV, as stated in paragraph 5.235 of Chapter 5, this may be explained by the fact that Brian's Hepatitis C positive test result was reported only a month before his death. If he was not told this diagnosis, any failure on the part of the doctors to disclose this diagnosis may be mitigated by the short interval between Brian's diagnosis with HCV and his death. Understandably, Elaine suffered some anxiety when she discovered that her husband had this virus. She was concerned that he could have passed the virus to her and that she could have had it for a number of years without knowing and without receiving treatment. As stated in paragraph 32.207 of Chapter 32, family members of competent adult patients had no right to know a diagnosis and so, while the failure to inform her caused her distress and anxiety, there was no duty on the part of those treating Brian to inform Elaine of his diagnosis.

## Glasgow

**34.208** There is no evidence of anti-HCV testing of stored samples without consent in the GRI or Yorkhill.

**34.209** David's recollection that he was not told much about the virus when he was diagnosed with it in 1991 is consistent with Professor Lowe's evidence that, in the early 1990s there were several deficiencies in knowledge about the virus.<sup>240</sup>

---

<sup>240</sup> See paragraph 34.103 above

**34.210** According to Christine, her son, John, was unaware when he died in March 1995 that he had Hepatitis C. His medical treatment was transferred to the GRI from Yorkhill, in 1991 when he was 16 years old.<sup>241</sup> The referral letter recorded that John was positive for the antibody to Hepatitis C. Further tests will undoubtedly have been carried out at the GRI to confirm this diagnosis. There is perhaps a very remote possibility that John was aware of this diagnosis or even that he was told it, but due to the ongoing monitoring and treatment for AIDS, it did not register with him or even sufficiently for him to tell his parents about it. Against this possibility is Christine's evidence that John would have told her or her husband had he known. A further explanation is that the medical staff at the GRI assumed that John had been told he was positive to the antibody to the virus while still a patient at Yorkhill, and so did not discuss it further with him. These explanations can only be conjecture and no conclusion can be reached about what John was or was not told about his diagnosis with Hepatitis C. Whatever happened, the manner in which Christine found out that her son had the virus was insensitive, to say the least, and can only have added to her suffering.

### Dundee

**34.211**, There is no evidence that haemophilia patients in Dundee had given their consent to have their LFTs monitored or had consented to having samples stored prior to Professor Cachia's appointment. The available evidence from Professor Cachia suggests the contrary.

**34.212** In relation to testing stored samples for anti-HCV, the timing in Dundee was substantially the same as in Edinburgh. Stored samples of sera were tested with the new HCV test when it became available in about 1989 and results were not communicated to patients until about 1992. That delay was inappropriate.

**34.213** It appears that the system for communicating test results to patients broke down in relation to Colin who was told his diagnosis with Hepatitis C by telephone and in an insensitive manner. The system for informing patients of their test results, which Professor Cachia sought to implement, failed in Colin's case as systems sometimes do. The reason for this is unknown.

### Stephen

**34.214** As noted in paragraph 34.3 above, practices at Edinburgh, Glasgow and Dundee have been explored in detail in this chapter as practitioners from these areas gave evidence to the Inquiry. A discrepancy arose in the evidence of Stephen, who was treated in Aberdeen, surrounding his diagnosis with Hepatitis C.<sup>242</sup> In summary, despite Stephen's medical records recording that Stephen had been found to have antibodies to Hepatitis C in 1992 and that he discussed his diagnosis with doctors in 1995, Stephen thought that he became aware that he had Hepatitis only in the late 1990s or early 2000s. No clinicians involved with Stephen's care gave evidence to the Inquiry and so this issue was not explored in detail at the public hearings. For this reason it is inappropriate for the Inquiry to form a view about when Stephen was told of his diagnosis with Hepatitis C. That said, this discrepancy may be an illustration of a point already made in this chapter which is pertinent to the issues in this series of chapters, namely that just because a diagnosis was conveyed by a doctor did not necessarily mean that it was heard by the patient.

<sup>241</sup> See paragraph 34.106 above

<sup>242</sup> Paragraphs 6.18–6.23 of Chapter 6

### Patients who received HCV from blood transfusions

**34.215** The fact that it took almost two years, from 1994, for the cause of Molly's cirrhosis to be identified as Hepatitis C, is indicative of the lack of knowledge about the virus amongst more general clinicians (as opposed to haematologists) in the early days of the virus being discovered. The manner in which Molly was informed of her diagnosis was unfortunate, and is very likely to have contributed to her reaction to the diagnosis. Without specific guidance about conveying blood test results to patients, clinicians including GPs will have adopted their own approach to doing so. Many will have had little knowledge of the virus. As a result of this the manner in which blood transfusion patients, like Molly, were told of their diagnosis with Hepatitis C varied considerably.

**34.216** This is borne out by the other witness statements obtained by the Inquiry. The extent of the information patients, like Molly, were given about the virus will have depended on the knowledge of the person diagnosing them. In the early days of the virus many clinicians, through no fault of their own, will have had little information to pass on to patients and so patients will have been diagnosed with a virus but given very little information about it. This is likely to have added to their distress and anxiety on receiving such an uncertain diagnosis.

**34.217** Despite being diagnosed with NANB Hepatitis in about 1978, Gordon was not diagnosed with Hepatitis C until 1995 when he was admitted to hospital for investigation of his symptoms of the virus. It is unfortunate that his diagnosis with NANB Hepatitis did not trigger a test for Hepatitis C earlier, but by the time the test became available Gordon had moved to England. The procedure for testing patients with NANB Hepatitis for Hepatitis C in England is not within the remit of this Inquiry.

**34.218** Anne was diagnosed with Hepatitis C in late 1995 by her GP after being identified in the UK look-back exercise as a recipient of infected blood. After agreeing to counsel and test Anne, Anne's GP was provided by the SNBTS with written guidelines entitled 'Transfusion-transmitted Hepatitis C: Guidelines for counselling patients April 1995' which ran to 25 paragraphs over five pages. These guidelines included an introduction and sections on background, implications of a positive test – prognosis, epidemiology, modes of transmission, avoiding infecting others, further assessment and follow up and notes about management at specialist centres. Despite these guidelines, when he diagnosed her with Hepatitis C, Anne's GP gave her the impression the virus was nothing to worry about. He gave her very little information about the virus or the implications of it. It is unclear why Anne's GP did not convey to Anne the information he had been given but the outcome for Anne was that she was worried and concerned for her future. She sought further information herself from her local hospital.

**34.219** Christine's evidence is disturbing.<sup>243</sup> She did not want to receive Factor VIII in connection with surgery. She found that despite her wishes medical staff transfused her with Factor VIII, relying on a general waiver contained in her consent form to the surgery.

**34.220** It is very unfortunate that she was treated with what transpired to be infected Factor VIII when she did not believe that she required such treatment. Those who treated Christine did so on the basis of her consent to the surgery and this was indicative of the paternalistic nature of medical practice at the time.

---

<sup>243</sup> Christine – Day 28, pages 26-27

**34.221** It is understandable that Christine was shocked when she was diagnosed with Hepatitis C at a meeting with a representative of the SNBTS in 1991. After all her son, she and her family had been through this must have been particularly difficult information to hear. Her reaction to this is unlikely to have been helped by the questioning she received about drug-taking.

### **Final comment**

**34.222** The ethical principles and rules governing clinicians' relationships with their patients in the period covered by this chapter were not settled. The transition from 'doctor knows best' to the current (and still evolving) principle of patient-centred care was prompted by experience of managing and treating patients exposed to the risk of HIV/AIDS infection and to the associated risks of social exclusion and financial difficulties that arose with it. The course of events has been traced in Chapter 32. For present purposes it should be noted that it was in 1988 that the General Medical Council published its guide *HIV Infection and AIDS: The Ethical Considerations*. AIDS had become 'dramatically apparent' in about 1982–83. But the medical profession took time to understand the implications for clinical practice and the need to adapt to the challenges presented by this new and emerging infection.

**34.223** The risks of serious morbidity and of death associated with NANBH, later HCV, infection began to be generally understood late in 1985, in the middle of the AIDS period. The lessons from dealing with HIV/AIDS had not been fully understood and assimilated into general ethical practice by that time. The conclusions in Chapter 32 include that no criticism can be made of clinicians relating to their management and treatment of patients generally over the critical period down to the late 1980s. It would be the early 1990s before the position in relation to NANBH/HCV became clear and there was a basis in generally accepted principles and rules against which to measure the care of patients.

**34.224** The conclusions reached in Chapter 32 address issues of ethical practice. Developments in the principles and practice of medical ethics now in general application should ensure that patients receive the information they need to reach informed conclusions on their illness and on treatment.

**34.225** However, the complaints of patients and their families discussed in this chapter – very similar to those made in relation to the HIV virus – of inadequacies in the information provided to them about the Hepatitis C virus, in the manner in which their diagnoses were communicated to them, and about testing for infection without counselling and consent, serve to underline an important message for medical practitioners. Patients infected with a potentially fatal virus such as HIV, or infected with HCV and at risk of developing the serious complications of cirrhosis, possibly hepatocellular cancer, and other fatal complications, are entitled to this information and should not have to wait while the medical profession deliberates on general ethical issues. At a basic human level help is needed in real time as it becomes clear that the patient has acquired a serious infection or other illness.

**34.226** The examples discussed in this chapter, and in Chapter 33, reflect the anger and dismay of individuals discovering that their medical advisers had information about them, or intended to investigate their condition, without involving the patient in discussion about his or her health and the clinician's response to it. The examples of blood disorder patients are particularly telling. They and their clinicians had been confronted in the first half of the 1980s with the unprecedented, extreme and worrying circumstances surrounding AIDS

and, when it was established as the cause of the profound immune deficiencies leading to AIDS, the HIV virus. In the second half of the decade they were confronted by the reality that what had been seen, and represented to them, as a life-changing treatment which both extended life expectancy and promised an unprecedented quality of life experience, carried an additional risk, of developing serious and potentially fatal complications of a disease previously thought to be relatively benign. The result has been distress, anger and distrust of clinicians, clearly demonstrated by the evidence of witnesses at the public hearings and from witness statements received by the Inquiry.

## CHAPTER 35

### AN INVESTIGATION INTO THE STEPS TAKEN TO IDENTIFY THE INDIVIDUALS WHO WERE INFECTED (LOOK-BACK)

#### Introduction

**35.1** Previous chapters have discussed the information available to doctors about HIV and Hepatitis C virus (HCV) infection as knowledge of the diseases and their treatment developed, the provision of relevant information to patients, and the introduction of HCV screening in September 1991. This chapter deals with the methods available to identify patients put at risk of HCV transmission by treatment with blood or blood products, and with the steps taken in that regard.

**35.2** The methods of investigation available to regional directors included 'look-back'. Look-back seeks to connect information about patients, blood components or products thought to be transmitting infection and the donors who provided the blood. In practice, two types of look-back were developed, called in the UK 'targeted' and 'reverse' look-back.

**35.3** In 'targeted look-back' the process begins when a blood donor is found to be infected when tested for a specific pathogen such as HIV or HCV. The donation history of the infected individual is then investigated with a view to tracing possible recipients of blood, blood components or products prepared from previous donations by that person to ascertain whether such recipients may have contracted the virus harboured by the donor. Any blood, blood components or products derived from an infected donor still in stock can be identified; blood banks and peripheral hospitals can be advised and material they hold quarantined.

**35.4** In 'reverse look-back' (in North America often called 'trace-back') the process begins when a patient presents to a clinician with relevant signs and symptoms of a disease. In the case of HCV the clinician would often be a hepatologist and the signs and symptoms would be of liver disease. If investigations disclose HCV infection and there is a history of previous transfusion with blood, blood components or products, the clinician informs the relevant blood bank which then endeavours to trace the donor or donors who may have donated infected blood. Withdrawing blood, blood components or products is generally not possible as a result of reverse look-back, at least initially and often generally; the starting point is not the infective donor but the infected recipient and, quite often, the transfusion that transmitted infection will have taken place many years previously so that it would be almost certain that all of the blood, components or products derived from the implicated donation would have been used or gone out of date by the time of the investigation.<sup>1</sup> In contrast to targeted look-back, reverse look-back is not dependent on the availability of a screening test for the virus or its antibodies.

**35.5** This chapter is concerned primarily with look-back as it relates to HCV. However, the approach to HCV look-back was influenced by previous experience of exercises related to HIV and it is appropriate to comment on that experience in the first place.

---

<sup>1</sup> Components are allocated a limited shelf-life, or 'use-by' date.

## Early experience with look-back in the United Kingdom

**35.6** As discussed in Chapter 10, *Knowledge of the Geographical Spread and Prevalence of HIV/AIDS 2*, growing awareness of cases of AIDS among haemophilia patients, particularly those with Haemophilia A, in 1984–85 spurred attempts to estimate the prevalence of HIV infection in the UK. In Scotland, the infection of ‘the Edinburgh Cohort’ was discovered and disclosed at the end of 1984.<sup>2</sup> It was initially thought that one specific batch of Scottish National Blood Transfusion Service (SNBTS) Factor VIII concentrate had probably caused the infection but, at the time, a definitive investigation would have to await a reliable test for infectivity. All but one of the 16 patients with Haemophilia A who had developed anti-HTLV-III had received the so-called ‘implicated batch’ between March and May 1984.<sup>3</sup> At about the same time it was discovered that a number of west of Scotland patients had also been infected. Details were disclosed in May 1985.<sup>4</sup> These discoveries presented the initial data for a reverse look-back exercise, which concentrated on following up data from the Edinburgh and south east Scotland region.

**35.7** In this respect, the exercise was an illustration of the SNBTS’ ability to undertake reverse look-back procedure for investigating the histories of recipients of blood or blood products who had been found to be infected. It was a means, in at least some cases, of ascertaining information on transmission of infection, however difficult and limited in the circumstances, independent of the targeted look-back studies discussed in this chapter.

**35.8** The SNBTS recording system allowed the tracing of donations which had made up an ‘implicated batch’. Regional Transfusion Centres (RTCs) kept records of donations sufficient to identify the specific donors who had contributed to a batch of blood products thought to have transmitted infection.<sup>5</sup> It was then possible to follow up those donors who returned to later donation sessions and were screened.<sup>6</sup> As noted below, and discussed more fully in Chapter 28, *Donor Selection – AIDS*, at the same time as the SNBTS was attempting to identify ‘implicated donors’ there was a well-publicised, and effective, campaign to discourage ‘high-risk donors’ from donating blood.

**35.9** Subsequently, the SNBTS considered undertaking a look-back exercise aimed at tracing and testing the donors of all 4000 donations potentially associated with the transmission of HIV infection to the Edinburgh Cohort. These would have been all of the individuals who had donated blood which had contributed to the implicated batch, not just those who might have been captured as return donors. However, blood samples were available for only 50% of these donors and the view was taken that it would therefore be impossible to trace the course of donations by this method.<sup>7</sup>

**35.10** In one respect at least, the work done on HIV look-back was to have a lasting significance. In September 1984, Dr John Gillon was appointed as a Senior Registrar in the South East Scotland Blood Transfusion Service (SEBTS). He became a Consultant Physician in that service in April 1985. His responsibilities included the selection and medical care of donors.<sup>8</sup> On 20 November 1984 he was asked to visit transfusion centres and discuss

<sup>8</sup> Dr Gillon’s statement on HCV look-back [PEN.018.0410]

the care and selection of donors and to prepare a memorandum on the subject for consideration by the SNBTS Directors.<sup>9</sup>

**35.11** Around the time Dr Gillon took up his post, and following the introduction of an HIV test in late 1984, it was agreed across the UK that donor testing for HIV would be accompanied by targeted look-back, when donors tested positive on screening, from the outset. Dr Gillon assumed responsibility for this in his area, the south east Scotland region, and inherited files on the one or two historical look-back studies arising from instances where clinicians had identified an HIV-infected donor and carried out a targeted look-back.<sup>10</sup>

**35.12** By way of preparation, Dr Gillon and Dr Jan Davidson, one of the sessional medical doctors in his centre, had each spent one or two weeks at St Mary's Hospital in London with Dr Tony Pinching, who at that time had the largest cohort of HIV-positive patients in the country. Dr Pinching provided a counselling course on HIV testing at St Mary's, which Dr Davidson attended. Dr Gillon also visited the genito-urinary medicine (GUM) clinic and had discussions with microbiologists.<sup>11</sup>

**35.13** Dr Gillon and Dr Davidson shared the work of counselling blood donors found to be HIV-positive on screening. Dr Gillon took responsibility for counselling the patients who came to attention through the look-back exercise that followed identification of an HIV-positive blood donor, because the number of affected individuals was small. Dr Gillon explained that, through this work, he and Dr Davidson gained valuable experience of the sort of issues that would crop up when dealing with donors who either tested positive after donating blood or who were found to be infected through look-back.<sup>12</sup>

**35.14** Dr Gillon was later to play a significant role in the development of a local HCV look-back programme. He explained the procedure involved in reverse look-back in more detail, with reference to non-A, non-B Hepatitis (NANB Hepatitis).

**35.15** On receiving a report of NANB Hepatitis infection in the recipient of blood, blood components or products, the SNBTS would seek details of the relevant transfusion episode(s), including all of the units that were transfused, and would then identify the donors associated with the implicated blood, blood components or products and carry out investigations to see if they could find the donor(s) who had transmitted infection. This could clearly be an onerous task as all of the relevant donors would have to be recalled: sometimes there could be hundreds of donors although more often it would be a smaller number.<sup>13</sup>

**35.16** Having identified the donors possibly implicated in transmitting infection, those individuals would be called in, told there had been a problem with a patient who had received their blood (usually along with other donations) and that there was a need to investigate the source of infection. Each donor would have a full medical history taken with a view to identifying any possible risk factors and also have a liver function test performed. Before effective screening for HCV was introduced in the UK in 1991, the end result was often inconclusive, with the result that often both the donors and the SNBTS, as Dr Gillon remarked, were left 'in limbo to some extent'.<sup>14</sup>

## Experience of HIV look-back in the United States

**35.17** The history of HIV look-back studies in the USA was discussed in an article by MP Busch (University of California) in the journal *Transfusion*.<sup>15</sup> The first initiative calling for notification of HIV infection had arisen from the case of the infection of the 'San Francisco child' (discussed in Chapter 11, *HIV/AIDS Aetiology*, paragraphs 11.24–11.25). The US Centers for Disease Control (CDC) sponsored and funded investigations of all reported AIDS cases in an attempt to identify infected donors and thereby trace, enrol and follow recipients of their blood. However, only a few US blood centres participated in the programme until 1985, when routine donor screening was introduced. The term 'look-back' was adopted at that point to describe the process of tracing transfusion recipients of donations triggered by screening. The procedure was expanded by some blood banks to include other methods of investigation and, according to Busch, became slow and possibly inherently inadequate. The CDC recommended that physicians should consider testing recipients of multiple units of blood or components ('general look-back').

**35.18** When antibody screening for HTLV-III (later HIV) was introduced in the USA in 1985, targeted look-back was implemented without much discussion. Busch set out to test the effectiveness of the HIV look-back programmes with specific reference to the San Francisco Bay area. He reported that it was found that the implementation of early high-risk donor education coincided with a dramatic reduction in the frequency of infected donations and, consequently, in the risk to recipients. It was estimated that approximately 90% of infected, high-risk donors self-deferred or were deferred prior to the availability of specific anti-HIV screening. A second study reported that standard targeted look-back was only minimally effective. The conclusion was that:

[T]hese studies show that the overall yield and efficacy of HIV look-back programs were poor. Standard, targeted look-back was limited, ironically, by the effectiveness of early self-exclusion measures, in that almost all of those responsible for HIV infections had stopped donating before they could be identified by anti-HIV screening.<sup>16</sup>

Additional limitations included the high death rate of recipients of infected blood together with the delay in, and logistics of, manual record searching and individual recipient tracing and notification through hospitals and private physicians.<sup>17</sup>

**35.19** Busch predicted that standard targeted HCV look-back would be enormously cumbersome and expensive and would also be ineffective for the same reason as the HIV look-back programme: the vast majority of infected former donors would already have been deferred or excluded from donation by the 'surrogate' measures in force long before the anti-HCV test became available. Those individuals would be 'invisible' to targeted look-back. Busch noted that the US Public Health Service had recently decided not to recommend anti-HCV testing of previous transfusion recipients. The reasons given were that, first, HCV was endemic in the general population, unlike HIV which was an epidemically spreading fatal infection clustered in specific regions, with transfusion of blood, blood components or blood products a major route of transmission. Secondly, sexual transmission of HIV was well documented; in contrast modes of community spread

---

<sup>15</sup> Busch, 'Let's look at human immunodeficiency virus look-back before leaping into hepatitis C virus look-back', *Transfusion* 1991; 31:655–661 [PEN.017.2307]

<sup>16</sup> *Ibid* [PEN.017.2307] at 2311

<sup>17</sup> *Ibid* [PEN.017.2307] at 2311

of HCV were much less well understood. Thirdly, therapy for HCV infection was of limited effectiveness. Fourthly, the relative risk of HCV transmission in transfusion recipients was much lower in relation to the background risk of the illness than had been the case with HIV. Lastly, there were public health financial considerations that were peculiar to the USA.

**35.20** Busch stated:

So what do we do?

....

I am convinced that the appropriate response to this situation is an aggressive education campaign for both physicians and the lay public about the risks and benefits, both in the past and the present, of transfusions.<sup>18</sup>

**35.21** He advocated a well orchestrated, long-term education campaign, targeting past and future transfusion recipients and donors, and felt that the long-term gains from committing necessarily limited resources to this would 'far outweigh' the 'minimal short-term yield of any specific HCV look-back effort'.<sup>19</sup>

**35.22** Busch's paper was published in 1991. An anti-HCV test, first available in 1989, was introduced into routine screening in the UK in September 1991.<sup>20</sup> As the article indicates, in the USA 'trace-back' followed on from well-documented cases of post-transfusion NANB Hepatitis before the isolation of HCV allowed for specific testing, using 'surrogate testing' methods. Surrogate testing by the methods adopted in the USA was not adopted in the UK, as discussed in Chapter 27, *Surrogate Testing of Donated Blood for non-A, non-B Hepatitis*. The SNBTS Directors recommended in March 1987 that surrogate testing should be introduced in 1988 (or at least considered that its introduction was inevitable).<sup>21</sup> Others in the transfusion services in Scotland and England did not support the introduction of such testing. Nor did the government health departments in Scotland or England. Irrespective of the merits of the arguments about surrogate testing, it appears to be important to note that Busch's argument against 'trace-back' relied heavily on a factor that did not apply in this country.

### The institutional arrangements

**35.23** Difficulties with the administrative control of, and responsibility for, policy in Scotland in relation to transfusion generally have been discussed in Chapter 17, *Blood and Blood Products Management*. The events discussed in this chapter provide an illustration of some of the practical problems that arose from the lack of well defined boundaries between bodies with an interest in providing advice on, and in the implementation of, look-back. It is appropriate in the first instance to note the formal position.

**35.24** There were two national (UK) advisory committees with an interest in the topic of look-back during the material time. The Advisory Committee for Virological Safety of Blood, later renamed the Advisory Committee on Microbiological Safety of Blood or Microbiological Safety of Blood and Tissue, advised Ministers of all four territorial departments of the UK. To avoid confusion, this committee will be referred to in this

chapter as the ACVSB/MSBT. The Advisory Committee on Transfusion Transmitted Diseases, otherwise known as the Advisory Committee on Transfusion Transmitted Infections, gave advice to the ACVSB/MSBT on transfusion-transmitted infections but did not advise Ministers directly. This committee will be referred to as the ACTTD/I.

**35.25** Nominally, statutory responsibility for the provision of blood and blood products in Scotland was devolved to the Common Services Agency (CSA). Evidence before the Inquiry, however, would suggest that for most practical purposes the SNBTS operated independently of the CSA in technical and scientific matters, in direct contact with the Scottish Home and Health Department (SHHD). An additional advisory committee, the Medical and Scientific Committee (MSC) of the SNBTS, was established in August 1990 and had its first meeting for regular business on 6 November 1990.<sup>22</sup> The MSC advised the SNBTS Board and became closely involved in the topic of look-back.

**35.26** Mr David McIntosh was Chairman and General Manager of the SNBTS from 1990 until 1996 and was responsible for the overall performance of the service at the time anti-HCV screening was introduced and the issue of look-back was under active consideration. In 1996, by mutual agreement between himself and his employers, his contract was not renewed.

**35.27** He said that, when he joined the SNBTS in 1990, it was run by the Regional Directors. They were members of a national organisation but mainly ran their own transfusion services in the major cities in Scotland independently of centrally imposed policies. All of the Directors were medically or scientifically qualified. The commonly accepted assertion of professional clinical independence meant that, within their regions, Directors could run things and make their own decisions almost as they wished, provided it conformed to the overall ethos of the SNBTS.<sup>23</sup> He found that 'none of the normal management common sense you can take for granted in most organisations outwith the public sector applied'.<sup>24</sup> Mr McIntosh described the difficulties he faced in attempting to introduce modern management practice to the SNBTS and, in particular, the resistance he encountered from the medically and scientifically qualified Directors with whom he had to deal.<sup>25</sup>

**35.28** He was asked about his role in establishing, and subsequent involvement with, the MSC. After three months with the SNBTS he recommended they set up a Medical and Scientific Committee as an advisory scientific sub-committee of the SNBTS Board in order to make a clear distinction between the medical and scientific side of the SNBTS and the managerial wing that he, as general manager, was responsible for.<sup>26</sup> His role in relation to the committee, he felt, was to help professional colleagues to come to clear conclusions on appropriate recommendations, intervening in detailed debate if asked to do so and ensuring that an appropriate, practical plan of action was prepared, authorised and implemented when decisions were reached. He assisted the members in achieving their goals by, as he put it, 'cajoling and persuading and coaching', but attended MSC meetings only occasionally.<sup>27</sup> Mr McIntosh commented that the role of the committee 'should have been to produce lucid recommendations'.<sup>28</sup> He went on to point out that

<sup>28</sup> Ibid page 79

a public health exercise like look-back was not just about the SNBTS testing blood: it would involve the cooperation of haemophilia directors, hepatologists, GPs and hospital administrators.<sup>29</sup>

**35.29** The impression Mr McIntosh gave of his early experience was of frustrated impotence in the face of an organisation that had been in existence for 50 years, staffed by highly qualified professionals (20% of whom had PhD degrees) without ever having any expert management.<sup>30</sup> He felt that the MSC came to be 'the government in exile of the SNBTS', with precedence over 'silly little administrative people called "managers"'.<sup>31</sup> Professor Cash did not consider that Mr McIntosh's assessment of the managerial competence of the SNBTS was accurate, observing that many of the tools of modern management were already in place throughout the SNBTS when Mr McIntosh took over. He pointed out that prior to the arrival of the General Manager the service had developed successful Research and Development programmes which were internationally recognised. The size and complexity of these Service and Research Developments were of such a magnitude that their success was inevitably dependant on at least some aspects of sound modern management practice.

**35.30** Dr Mitchell and Professor Urbaniak also did not accept Mr McIntosh's suggestion that prior to his arrival there had been an absence of expert management. Professor Urbaniak noted that in about 1986 the General Manager of the CSA introduced a number of seminars and courses on management principles for all the senior officers of the CSA. The SNBTS Directors, whose responsibilities within their respective regions included budgeting and staff, attended those events. Professor Cash did not accept that Mr McIntosh had been met with collective resistance to managerial change. Dr McClelland considered that the history and managerial structure of the organisation might have resulted in certain tensions arising at a higher management level. Neither Dr Brookes nor Professor Urbaniak accepted Mr McIntosh's description of his relationship with the Regional Directors, the latter suggesting that assistance given to Mr McIntosh by the Directors due to his unfamiliarity with the public sector might have been misinterpreted by him as resistance.

**35.31** Dr Perry, whilst aware of Mr McIntosh's concerns and frustrations in connection with perceived resistance from SNBTS Directors, considered that he and the General Manager had enjoyed a productive and mutually supportive relationship which resulted in many positive developments and outcomes. Whether Mr McIntosh's assessment of the position was correct or fair is, perhaps, of less significance than the fact that he clearly believed that his management was resented and that he had little managerial authority over the affairs of the SNBTS. What is clear is that regional autonomy gave Directors the scope to adopt their own policies and that became important in the context of HCV screening generally and HCV look-back in particular.

## **Donor screening for HCV**

### *Early screening in Scotland*

**35.32** On 21 June 1990, Professor Cash wrote to Dr Gillon in anticipation of the commencement of full anti-HCV donation screening, inviting him to chair a working party to draft operational guidelines, for consideration by the SNBTS Directors, on

---

<sup>29</sup> Ibid page 81

<sup>30</sup> Ibid pages 77-78

<sup>31</sup> Ibid page 79

counselling<sup>32</sup> donors confirmed to be anti-HCV positive.<sup>33</sup> As there was a wish to see as much harmonisation north and south of the border as possible, he asked Dr Gillon to keep Dr Harold Gunson, adviser on blood transfusion to the DHSS, informed.

**35.33** As a result of the HIV exercise, the south east region of the SNBTS (the SEBTS) and other regions held extensive archives of samples of blood donations. The first archive of blood samples started in the SEBTS in the middle of 1984 and Dr Gillon said that by early 1986 all of the Scottish centres were laying down a sample of every donation. That has continued to this day and all of those samples, very many millions, are still retained, apart from those that have been used up in retrospective testing.<sup>34</sup>

**35.34** Dr Gillon's previous experience indicated that, though the numbers of donors found positive for HIV were not huge, there were some regular donors among them. The working group was aware of the experience of researchers in San Francisco, reported by Dr Busch, and knew that look-back was not an easy process.<sup>35</sup> They also knew from their own experience with HIV that HCV look-back would be difficult.<sup>36</sup> Dr Gillon said that, with a new HCV test, it was likely that within the first six months of testing a large proportion of regular donors would be processed and that there would be a 'hump' in the curve of infections found following the introduction of a new test. Dr Gillon's working party came to a unanimous decision that there should be a look-back following identification of donors found to be HCV-positive. This was recommended in its report which went to the Directors of the SNBTS for discussion.<sup>37</sup>

**35.35** The availability in 1990 of first-generation HCV tests in Scotland for validation studies, gave some indication of the number of individuals likely to be involved. Dr Eddie Follett and Dr Brian Dow (West of Scotland Blood Transfusion Service) had first-generation kits to examine and had looked at some archived samples and, Dr Gillon thought, probably some fresh donor samples as well. The numbers were daunting and gave rise to the anticipation of considerable logistical and resource issues. Dr Gillon explained that initially it looked as though 0.5–0.6% of Scottish donors would test positive for antibodies to HCV. Based on assumptions about the daily rate of donations given on weekdays, this indicated that about 10 samples a day in Scotland would test positive for HCV and it was clear that a look-back exercise based on those numbers would require extra resources. He explained that the likely requirement for extra resources was one of the reasons why he felt that the working party made an early recommendation to commence look-back by saying 'in principle we think this needs to be done'.<sup>38</sup>

**35.36** The recommendation was inconsistent with discussions that had been progressing at national (UK) level and it is appropriate to note these before returning in more detail to the output from Dr Gillon's working group.

---

<sup>32</sup> 'Counselling' in this context refers to discussions with individuals unexpectedly found on donor screening possibly to be harbouring the HCV. It has to be distinguished from the 'counselling' of NHS patients in the course of investigation or treatment discussed in Chapter 32, *An Investigation into the Systems in Place for Informing Patients about the Risks – Ethical Context*, before a blood test is taken and relating to what would follow if the result of the test were positive.

*Discussions at the United Kingdom level*

**35.37** On 1 May 1990, Professor Cash wrote a letter to Dr Gunson headed 'HCV: Look Back'.<sup>39</sup> In the letter, Professor Cash suggested that, in advance of anticipated universal HCV testing of donations, the tests then available should be used in cases of post-transfusion NANB Hepatitis 'so that we can more readily locate "the offending donor" with a view to taking him/her off the panel'. From its terms, the letter, and Dr Gunson's reply (referred to below), related to reverse look-back as defined by Dr Gillon. Dr Gillon thought that this correspondence between Professor Cash and Dr Gunson related to reverse look-back. Professor Cash confirmed in evidence that he was not referring to targeted look-back at this stage.<sup>40</sup>

**35.38** As reflected in his evidence, Professor Cash's recollection of the background to the correspondence was poor. He said that he could not remember what specific discussions he had held with Dr Gunson at about this time. In general terms, however, he said that Dr Gunson was 'pretty unenthusiastic for a very long period of time, at the whole notion of look-back because ... for England and Wales, the nature of their structure of their transfusion services made it ... a giant of a task'.<sup>41</sup> In what appears to have been his reply to Professor Cash, Dr Gunson wrote on 21 May 1990 commenting that he was unsure whether RTCs in England and Wales would have access to anti-HCV test material and suggesting that it might be worthwhile carrying out 'the usual investigations' when a transfusion-associated NANB Hepatitis case was reported and to ensure that a library sample of serum was retained from each donor seen.<sup>42</sup> At that time, the 'usual investigations' referred to reverse look-back. The letter referred to an intended meeting on 27 June but in his oral testimony Professor Cash could not recall if the topic of look-back was, in fact, discussed when they met.<sup>43</sup> The Inquiry was left with Professor Cash's general impressions of the developing position.

**35.39** Professor Cash said that his initial response to Dr Gunson's position was to accept his reservations, at least for a while, describing his attitude as: 'Okay, we will buy it so far, Harold'. Subsequently, however, he said that he 'took this matter further'. Professor Cash was asked why he thought it was an important factor in making a decision about look-back that he had to discuss the topic with Dr Gunson and then report to the SNBTS. It was suggested to him that it should, perhaps, have been the other way round, that he should have first discussed the matter with the SNBTS Directors and then held discussions with Dr Gunson. In response, Professor Cash said that, as could be seen from contemporaneous correspondence, he did, in fact, discuss it with the SNBTS Directors and had said to them that he would start liaising with his counterparts in England and Wales: 'So it had been discussed, as I understand it, before July 1990'.<sup>44</sup>

**35.40** Professor Cash was, however, unable to recall in detail the relevant facts and circumstances that would have clarified his position on look-back at this period. He acknowledged that at this point the SNBTS did not have a general policy, saying: 'we were fishing around to explore are we really going to push this or not ...'. As noted, the SNBTS had instituted a look-back procedure for HIV and Professor Cash considered that the SNBTS ought to have at least been thinking about something similar in relation to HCV.<sup>45</sup>

<sup>43</sup> Professor Cash – Day 85, pages 10–11

<sup>44</sup> Ibid page 15

<sup>45</sup> Ibid pages 11–12

**35.41** Dr Gillon provided some background information on what was happening in Scotland at the time.<sup>46</sup> As noted above, in 1990 some limited reverse look-back was being done by SNBTS doctors. However, it was on an informal and less than systematic basis. SNBTS doctors knew that Dr Follett could test 'implicated' donor samples and they would ask him to do that and follow up the results. Dr Gillon said that 'it would have been crazy not to'.<sup>47</sup> However, targeted look-back could only begin once routine donor screening was introduced across the donor population. The impression given by Dr Gillon's evidence was that practice on the ground was more varied, and in some respects and in some regions more developed, than was implicit in the correspondence between the medical directors.<sup>48</sup>

**35.42** Professor Cash's letter of 1 May 1990 to Dr Gunson was copied to the Scottish Directors, including Dr Ruthven Mitchell who was a member of the ACVSB/MSBT. In a letter dated 14 May, Dr Mitchell defined the problem from a UK perspective: whether or not the UK blood transfusion services generally (the SNBTS and the NBTS) should have a policy of identifying donors who may have transmitted disease when there had been a report of NANB Hepatitis transmission.<sup>49</sup> He noted that he had raised the issue at a recent meeting of the ACVSB/MSBT, and reported:

I have advised Bob Crawford at the present time that we have no look-back policy, although you will understand that in doing so, the Service could be considered to be negligent in not advising about potential future use of donor blood.

At this stage, therefore, look-back was not supported by blood transfusion service policy.

**35.43** Professor Cash suggested that Dr Mitchell was also signalling in this letter that, if the SNBTS did think about a look-back programme that would include the west of Scotland (where Dr Mitchell was Director), it was going to be 'a big, difficult problem'.<sup>50</sup>

**35.44** The UK policy position appears to have become further refined by early July. On 9 July 1990 Professor Cash wrote to Drs Whitrow, Urbaniak, Brookes, McClelland, Mitchell and Perry, copying the letter to Dr Gunson and Mr McIntosh.<sup>51</sup> He stated:

[I] have discussed this topic with Harold Gunson.

We both agreed the following:

(a) It would not, after we start anti-HCV donation screening, be appropriate to introduce a systematic look-back programme on previous recipients – as was done for HIV-1.

(b) It would be appropriate, in the period before routine anti-HCV donation screening commences, to examine the anti-HCV status of donors who have been implicated in a case of reported PTH [post-transfusion hepatitis].<sup>52</sup>

**35.45** Professor Cash's letter to Dr Gillon dated 21 June 1990 inviting him to chair the drafting of operational guidelines was therefore written against a background of continuing debate about look-back exercises generally. By the time Dr Gillon submitted his working group's proposals, a preliminary decision had been reached at the UK level not to begin a programme of targeted look-back when donor testing for HCV commenced.

### **Draft guidelines**

#### *First draft*

**35.46** Against the background of these exchanges between the medical directors, Dr Gillon's group proceeded to prepare a draft guidelines document on donor counselling as requested in Professor Cash's letter of 21 June.<sup>53</sup> A copy of a draft was sent to Professor Cash on 20 September 1990.<sup>54</sup> The document took the form of a report to Professor Cash as National Medical Director of the SNBTS.<sup>55</sup> As indicated in the letter, an earlier draft of the guidelines had been sent to Dr Gunson for comment but by 20 September comments had not been received. Dr Gillon anticipated that the MSC would debate the guidelines.

**35.47** The draft guidelines reflected the group's view that it was important for careful consideration to be given to the provision of information to all blood donors. The draft contained detailed proposals for counselling donors found positive for anti-HCV on screening. The working group had received information that there had been practical difficulties in donor counselling in the north region and commented:

The Group therefore agreed that the extent of counselling and investigation undertaken must be at the discretion of any RTD, depending on local circumstances. It is our view that our duty is to inform the donor personally, ie at an interview with a member of SNBTS medical staff or another doctor recruited for that purpose.<sup>56</sup>

**35.48** Follow-up investigations would involve the donor's GP or a local specialist. The report also formally introduced the notion of HCV look-back:

The Group discussed the question of lookback. Donors may well ask about the outcome of their previous donations, and a clear policy on lookback is essential. We note the logistical difficulties, which have been taken as justification by the AABB [American Association of Blood Banks] for not recommending a lookback, but our view was that this position is untenable in view of the desirability of informing recipients so that they can protect others, and also receive treatment with Interferon if the benefits of this form of therapy are confirmed.<sup>57</sup>

**35.49** The final part of the report contained advice on 'informing the donor'.<sup>58</sup> Dr Gillon said that it was an attempt to be very practical. The working group was trying to describe in very clear terms what needed to be done to make the look-back work so that doctors who did not have much experience of look-back would be able to do it with little additional training. It was not envisaged that this section would be given to the patient. Rather, it

---

<sup>53</sup> Letter from Professor Cash to Dr Gillon dated 21 June 1990 [SNB.005.5023]

<sup>54</sup> Letter from Dr Gillon to Professor Cash dated 20 September 1990 [SNB.004.5074]

<sup>55</sup> Draft report for National Medical Director, *Donor Counselling: HCV*, dated 20 September 1990 [SNB.005.3647]

<sup>56</sup> *Ibid* [SNB.005.3647] at 3649

<sup>57</sup> *Ibid* [SNB.005.3647] at 3650

<sup>58</sup> *Ibid* [SNB.005.3647] at 3654

would be used by the doctor to impart information and was framed as a set of potential questions and suggested answers.<sup>59</sup>

**35.50** One of the questions a donor found to be infected might ask of a consultant, Dr Gillon noted, was 'what about my previous donations?'. The guidelines provided possible answers to this question together with general advice:

The recipients of previous donations will be traced and their Consultants or GPs informed. We hope to obtain results of any tests carried out. However, it may cause distress to the donor to discuss this matter in any detail. A general comment suggesting that we are going to check to see that the recipients are alright, that they get any treatment they may require, should be sufficient.<sup>60</sup>

**35.51** Dr Gillon said that this was a reference to targeted look-back.<sup>61</sup> As indicated above, this proposal was at variance with the policy position agreed between Professor Cash and Dr Gunson.

***First draft: reception and reaction***

**35.52** Professor Cash said that he realised when he read the draft guidelines that Dr Gillon was advocating a look-back policy. He did not accept that it was an expression of SNBTS policy. Rather, it was a proposal from Dr Gillon's working group which was delivering the view that the SNBTS needed to do a look-back. He considered that it was an issue that the SNBTS needed to think about carefully.<sup>62</sup>

**35.53** Professor Cash circulated the report prepared by Dr Gillon's group to Dr Perry and the Regional Directors, Dr Brookes, Dr McClelland, Dr Mitchell, Dr Urbaniak and Dr Whitrow, on 4 October 1990 with a copy to Mr McIntosh for information.<sup>63</sup> The letter asked the Directors to review the report before the MSC meeting on 6 November 1990.

**35.54** Dr Gillon was not a member of the MSC, but attended part of the meeting on 6 November to present his guidelines document. As the minutes of the meeting make clear, the report was discussed before he joined the meeting.<sup>64</sup> Dr Mitchell is reported to have advised that 'Dr Gunson was anxious to take this Gillon document to the National Advisory Committee in the near future'.<sup>65</sup> Dr Gillon then joined the meeting and gave a brief summary of the report, following which there was lengthy discussion. Dr Gillon did not have a clear memory of the discussion about the guidelines. He drew attention to paragraph 10 of the minute, headed 'HCV Look-Back', which recorded that:

After discussion it was agreed that Professor Cash should write to the Chairman of the DoH Advisory Committee on the Virus Safety of Blood, asking that careful consideration be given to the matter of HCV look back of recipients of previous donations.<sup>66</sup>

<sup>65</sup> *Ibid* [SNB.009.5513] at 5516

<sup>66</sup> *Ibid* [SNB.009.5513] at 5519

**35.55** Dr Gillon said that decision was a reference to targeted look-back. His recollection was that the MSC at this stage had a generally positive attitude to targeted look-back. However, he thought that there were some people who had reservations, particularly in the west of Scotland, where, as Professor Cash had noted, the size of the region and number of people involved could pose logistical problems. He recalled that even Dr Crawford, who was a member of the working party which had put forward the recommendations, was 'very leery' of look-back because of the amount of work it would create. Dr Gillon felt that the answer to that was to provide more resources: he and his colleagues would need secretarial help. He did not consider that they were talking about a vast amount of money but they knew that they would need extra funds to carry out the work.<sup>67</sup>

**35.56** It was agreed by the Committee that Dr Gillon should re-draft the document:

- (i) In a format which was that of professional/operational guidelines.
- (ii) That counselling information which all HCV confirmed positive donors would be advised was clearly delineated.
- (iii) That thereafter a series of supplementary questions/answers were made available.
- (iv) That consideration be given to including information on the treatment of HCV hepatitis and the issue of safe sex.<sup>68</sup>

**35.57** Dr Gillon agreed to prepare a draft Standard Operating Procedure based on the report by 30 November 1990 for submission to the members of the MSC for their consideration.<sup>69</sup>

**35.58** Dr Gillon recalled that Professor Cash wrote to him and said that the guidelines were 'very well received' and that the Scottish Directors had accepted them and that he would be sharing them with colleagues in England and discussing it with them.<sup>70</sup>

**35.59** In his oral evidence, Professor Cash was initially unable to recall what his own attitude was to look-back at that point although he thought that he was 'enthusiastic', though not without reservation.<sup>71</sup> He went on to say that he was a 'strong supporter of look-back' but that his reservations related to the absence of treatment for HCV at the time: 'I was very warmly in favour [of the idea of look-back], but I wasn't prepared to push it until I had some good evidence ... that there was a treatment option'. He thought this was 'a very interesting philosophical issue' and that his attitude probably reflected attitudes common at the time: 'I had been brought up in a different era, in which doctors should do their best, as part of their caring, to filter in some way stuff that really they didn't feel the patient needed to know'.<sup>72</sup> As discussed in Chapter 32, *An Investigation into the Systems in Place for Informing Patients about the Risks – Ethical Context*, the approach of the medical profession to patients up to at least the mid-1980s was generally 'paternalistic' in nature, and only progressively less so in the early 1990s. As presented in evidence, Professor Cash's reservations may reflect that stance when he said: 'if you haven't got some good news for the patient, i.e., "We have got some treatment here that can be of serious benefit to you," ... loading a lot of innocent people with bad news,

unnecessarily, is not a good thing to do'.<sup>73</sup> However, as Dr Gillon pointed out, the lack of treatment for HIV was not considered sufficient reason for not introducing targeted HIV look-back in the mid-80s.<sup>74</sup>

### **Perceptions at the United Kingdom level**

**35.60** Following the MSC meeting of 6 November 1990, Professor Cash wrote to Dr Jeremy Metters, Deputy Chief Medical Officer at the Department of Health (DoH) and Chairman of the ACVSB/MSBT. The letter, headed 'HCV: Donation Testing: Look back',<sup>75</sup> said that the SNBTS Directors had asked Professor Cash to write requesting that the ACVSB/MSBT consider a policy of look-back in anticipation of the commencement of testing blood donations for HCV throughout the UK. In oral evidence, Professor Cash said that he had come to the conclusion that look-back was something about which the SNBTS ought to 'touch base' with the advisory committee, although he was not sure whether he had come to this conclusion because of discussions with Dr Gunson or SNBTS colleagues. He explained that it was important to him that Dr Archibald McIntyre, SHHD, Dr Mitchell and Dr Perry received a copy of the letter because they sat on the ACVSB/MSBT. They had been briefed and knew that the Scottish Directors were very keen that look-back should be discussed.<sup>76</sup> In its terms, the letter appears to follow the decision of the MSC of 6 November, though with less specification of the interest of the members of the committee.

**35.61** Professor Cash explained that the reason he wanted the ACVSB/MSBT to consider the question of look-back was because he was of the view that initiating look-back would require the Chief Medical Officer (CMO) to instruct the Regional Health Authorities in England and Wales and the Health Boards in Scotland and because it would require the active collaboration of clinicians and peripheral laboratories. He stated that 'the only route we had at that time, that I am aware of, to get into ministerial approval was the Metters committee'.<sup>77</sup>

**35.62** At this stage, it is important to note that the precise sequence of events is less than clear. The ACTTD/I met on 8 January 1991.<sup>78</sup> There was extensive discussion of the procedures to be put in place for anti-HCV screening. Dr Gillon's paper was discussed, as was a paper by Dr Contreras. Dr Gillon agreed that he would amend his paper in the light of written comments he was to receive from Dr Contreras and others. It was noted that arrangements should be made for counselling donors reported to be positive by recombinant immunoblot assay (RIBA) and subsequently confirmed as positive by a polymerase chain reaction (PCR) test. In further discussion, it was agreed that:

[T]here may be an ethical obligation to inform patients who may have received transfusions in the past from anti-HCV positive donations. This will involve considerable additional work including testing of library samples and will have to be funded. Extension of this to epidemiological investigations should be the subject of separate research studies.<sup>79</sup>

<sup>78</sup> Minutes of meeting of UK Advisory Committee on Transfusion Transmitted Diseases on 8 January 1991 [SNB.001.8770]

<sup>79</sup> Ibid [SNB.001.8770] at 8773

**35.63** After its meeting on 6 November 1990, the MSC next met on 19 February 1991. In relation to donor counselling, the minutes of the meeting state:

The Committee examined Dr Gillon's final draft document, which had been previously circulated and agreed it was excellent. The Committee proposed and agreed that the latter pages be used as Guidelines in leaflet form for use by the RTCs.

In the light of national events, it was agreed no "Look Back" should be introduced at present.<sup>80</sup>

From the terms of the minutes it appears that intelligence was available that there had been a decision at the UK level that HCV look-back should not be implemented. The ACVSB/MSBT had last met on 21 November 1990. It would next meet on 25 February 1991.<sup>81</sup> It could not have been involved, as a committee, in articulating objections to screening on grounds of 'national events'. The Inquiry has not uncovered any record of 'national events' leading to an agreement that look-back should not be introduced at that stage.

**35.64** Professor Cash was unable to recall what the 'national events' referred to were. He said it was possible that 'signals' had been made through Dr Gunson to him indicating that the ACVSB/MSBT was minded to reject look-back at their next meeting, as discussed below, and that he had reported this to his colleagues.<sup>82</sup> He later suggested that he may have spoken with Dr Gunson directly in advance of the MSC meeting and become aware that 'look-back was not a runner at the moment'.<sup>83</sup>

**35.65** Professor Cash also said that he could not recall whether there had been much discussion about the advisability of proceeding with look-back at the MSC meeting, beyond what is recorded in the minutes. He did not accept that he would have gone to the meeting and simply explained that, because it appeared that look-back was not going to proceed in England and Wales, he did not think it would be possible to do look-back in Scotland. He thought it more likely that he thought that it would be necessary to 'get more ammunition' to press the case for action in Scotland.<sup>84</sup>

**35.66** The ACVSB/MSBT held its ninth meeting on 25 February 1991.<sup>85</sup> The events leading up to that meeting are discussed in detail in Chapter 31, *The Introduction of Screening of Donated Blood for Hepatitis C*. On 21 November 1990 the ACVSB/MSBT had sufficient information about the test kits then available, manufactured by Ortho and Abbott, to conclude, on Dr Gunson's advice, that the kits could be 'deemed' to be satisfactory for routine use.<sup>86</sup> The committee concluded that a combination of RIBA and PCR tests would provide a confirmatory service and agreed that it was important to start screening as soon as possible.<sup>87</sup> A full submission was sent by the DoH to Ministers on 21 December 1990.<sup>88</sup> Discussion of the delay that then occurred in processing Ministerial consideration of the issue need not be repeated here. What is relevant is that, as time passed, the emphasis shifted to the need for 'proper' evaluation of the second-generation Abbott and

<sup>88</sup> Submission dated 21 December 1990 [SGH.002.7893]

Ortho kits that were expected to become available in July 1991.<sup>89</sup> Abbott had launched their second-generation test on 8 April 1991.<sup>90</sup> More widely, financing the introduction of screening had increasingly become recognised as a problem for health authorities in England and Wales. The start date for screening of 1 September 1991 was adopted against that background.

**35.67** On 25 February 1991 the ACVSB/MSBT understood that licensing of the second-generation kits by the US Food and Drug Administration (FDA) had not been completed, that issues over patent rights had not been resolved and that further tests might identify new markers of infection.<sup>91</sup> There was an air of uncertainty about the screening kits that might be selected. All 10,000 of the archived samples already tested were to be re-tested by second-generation kits.<sup>92</sup> Funds for continued testing were to be sought by RTCs through normal channels.

**35.68** At the meeting, Dr Mitchell reported orally on the discussions at the recent meeting of the ACTTD/I, and in particular on the procedures for anti-HCV testing.<sup>93</sup> In relation to look-back, paragraph 14 of the minutes of the ACVSB/MSBT meeting states:

The Committee discussed the problems of look-back and recommended that it should not be undertaken as a service, leaving the option for those carrying out research. However, all cases of post-transfusion hepatitis should continue to be investigated.<sup>94</sup>

The reasons for this recommendation were not minuted. The second sentence appears to support reverse look-back, leaving it unclear whether the first sentence relates to all forms of look-back.

**35.69** Professor Cash explained that the phrase 'not undertaken as a service' meant that look-back would not be a routine part of the Blood Transfusion Service delivery. Asked if this applied to all blood transfusion services throughout the UK, Professor Cash replied that it was his understanding that the Ministers who were being advised by this committee included Scottish Ministers, although that did not necessarily prevent Scotland 'doing their own thing'.<sup>95</sup>

### *The position of the Scottish Home and Health Department*

**35.70** There was no direct evidence available to the Inquiry of the position adopted by the SHHD at this stage. Dr Aileen Keel, Acting Chief Medical Officer for Scotland at the time of this Report, was appointed a Senior Medical Officer in the SHHD in March 1992 and was, therefore, not in office at the material time in 1990 and 1991 when targeted look-back was first discussed. She commented on the documentary evidence available from the earlier period and from her personal experience from 1992 onwards.

<sup>93</sup> *Ibid*

<sup>94</sup> *Ibid* [SNB.001.8934] at 8939

<sup>95</sup> Professor Cash – Day 85, pages 31–32

**35.71** Dr Keel was referred to the minutes of the meeting of the ACVSB/MSBT held on 25 February 1991.<sup>96</sup> Dr McIntyre, who was the Principal Medical Officer with responsibility for laboratories and blood transfusion when Dr Keel joined the department, was an observer at that meeting. When Dr Keel was appointed she took over responsibility for those areas and she thought that Dr McIntyre would probably have briefed her about previous meetings.<sup>97</sup> As noted above, the minutes of this meeting of the ACVSB/MSBT recorded the decision not to proceed with look-back.<sup>98</sup>

**35.72** Dr Keel agreed that the effect of the decision was that the advice to Ministers was that look-back should not be pursued. She was referred to an SHHD minute from Dr McIntyre to Mr Panton dated 10 July 1991.<sup>99</sup> Mr Panton was one of her policy colleagues who reported to Mr George Tucker, Assistant Principal, and was a key policy colleague in relation to look-back. The minute referred to a copy of recommendations for counselling HCV-positive donors, presumably Dr Gillon's working group document. Dr McIntyre was concerned with the comment in the minute that look-back would be initiated 'in accordance with SNBTS policy'. He queried whether look-back would be a good idea, because at that stage it was not clear whether those testing positive would have been infectious. He also commented: 'In certain circumstances it could also give rise to litigation and it may be that you would wish to discuss this particular point with our Solicitors before this policy is put into effect'. Although Dr Keel acknowledged that, from this memo, it appeared that Dr McIntyre was concerned that look-back might give rise to litigation, she could not remember this being an issue that was particularly stressed in discussions about HCV look-back at that time. The main memory that she had was that look-back 'wasn't considered feasible, that logistically it would be too difficult to undertake, rather than any major concerns around litigation'.<sup>100</sup>

**35.73** Professor Cash said he had no memory of concern within the Scottish Office at the time that look-back could give rise to litigation and did not consider that this was a factor that was taken into account when deciding about implementing look-back at this time.<sup>101</sup>

**35.74** So far as the evidence available to the Inquiry discloses, the SHHD position around mid-1991 was that targeted look-back had been advised against by the ACVSB/MSBT. There was no evidence that it was a 'live issue' for administrators in advising Ministers.

### **Reaction in the south east Scotland region to the Medical and Scientific Committee's decision of 19 February 1991**

**35.75** Professor Cash wrote to Dr Gillon on 12 March 1991 informing him that the MSC had agreed to the proposal that the latter pages of the draft guidance (those containing guidance on practice at RTCs) should be used nationally as guidelines in leaflet form within the RTCs.<sup>102</sup> However, he commented that 'in the light of national events' (a phrase repeated from the MSC meeting minutes of 19 February), the section answering the question, 'What about my previous donations' and implying that look-back would be implemented, 'should be omitted from the final document'. Professor Cash agreed that that comment was made because of the stated attitude of the ACVSB/MSBT.<sup>103</sup>

<sup>102</sup> Professor Cash's letter to Dr Gillon dated 12 March 1991 [SNB.005.1689]

<sup>103</sup> Professor Cash – Day 85, pages 40–41

**35.76** Dr Gillon said that, at the time, he had no idea what the phrase ‘in light of national events’ meant. He thought that he must have understood that there was disagreement in England about doing look-back. He did not recall ever being given an explanation by Professor Cash as to why the section relating to look-back had been omitted from the final draft. He thought that he would have understood it to be largely a resource issue but he knew that there were also some people in London who disagreed with look-back for ethical reasons: some clinicians had doubts about going ahead with look-back when affected patients could not be offered anything in the way of specific treatment. Despite an emerging body of evidence at this time about possible treatment with Interferon, his own 1990 guidelines having referred to it, Dr Gillon recalled that, if there was an ethical objection to look-back, it was ‘usually couched in terms of no treatment being available’.<sup>104</sup>

**35.77** Dr Gillon noted that by March 1991 second-generation tests were becoming available which were both more specific (that is, had a low false positive rate) and more sensitive (that is, had a low false negative rate) and would pick up more true instances of HCV infection. Initial evaluation exercises suggested that the number of people affected might reduce tenfold. He also noted that, around the turn of the year 1990–91, a confirmatory test for HCV (a PCR test) was in the later stages of development and that it was available for use by September 1991, when routine screening for HCV in blood donation began. Thanks to the innovative work of Professor Peter Simmonds, Scotland was one of the very few countries, and possibly the only country, that had PCR testing as part of their confirmatory process right from the start.<sup>105</sup>

**35.78** Dr Gillon said that when he received the letter from Professor Cash in March 1991 he was ‘pretty appalled’.<sup>106</sup> He believed that the MSC had agreed, at least in principle, to implement look-back. He was confident that, from an ethical point of view, it was right to proceed with look-back and he felt strongly that the health service should be doing look-back from the point when donor screening for HCV commenced, as had been the case when HIV screening was introduced. He felt that, even if there was difficulty in coping with the number of people involved or the reliability of test kits, the attempt should at least be made. If more resources were required, these should have been sought. He said that he was willing to debate the question with anybody. He did not have an opportunity to debate it with Professor Cash other than being at meetings such as the MSC where it had seemed to him to have been accepted that look-back should be implemented. He explained that it came as a bit of a surprise that Scotland was not going to be doing look-back.<sup>107</sup>

### **Screening technology: England and Wales and Scotland compared**

**35.79** Dr Graeme Alexander was asked by the Inquiry to comment on the introduction of the test for HCV antibodies in England and Wales and, later, the eventual introduction of the UK-wide HCV look-back programme in 1995. Dr Alexander was involved in the UK-wide look-back exercise as Chairman of the Hepatitis C Virus Steering Group, a body set up to ensure that the look-back strategy was managed ‘efficiently and effectively and in line with ethical standards’. A database was developed over time for research purposes, for those involved directly with the steering group and other people in the UK

<sup>104</sup> Dr Gillon – Day 86, pages 29–30

<sup>105</sup> Ibid pages 34–35

<sup>106</sup> Ibid page 31

<sup>107</sup> Ibid pages 31–32

with an interest in this area of research.<sup>108</sup> It is important to bear in mind that, although he became closely involved in the implementation of look-back in the UK as a whole, Dr Alexander's evidence of the background to the exercise reflected the experience of an English practitioner and was, in some respects, in marked contrast to Dr Gillon's evidence.

**35.80** Dr Alexander said that, when screening for HCV was introduced in England in September 1991, it was performed with a 'first generation' enzyme-linked immunosorbent assay (ELISA) kit. This assay proved to be both insensitive and non-specific (that is, gave rise to a large number of both false negative and false positive results) and a great deal of skill was required to ensure that the tests were interpreted appropriately. In particular, the false positive rate was between 50% and 70% when a low-risk population, such as blood donors, was screened.<sup>109</sup> So far, experience was similar to that described by Dr Gillon above; in Scotland also, the first-generation kits produced a very high rate of false positive results.

**35.81** Dr Alexander continued:

Within 18 months or so these tests were replaced by second generation ELISAs. At this point ... it was agreed generally that a second RIBA test ... should be performed before telling patients that they were positive for HCV.<sup>110</sup>

**35.82** The RIBA was often described as a 'confirmatory test' but Dr Alexander noted in oral evidence that the RIBA was really the same test as the ELISA, using the same proteins but performed using a different method. Nevertheless, it made practitioners more confident they had the correct test result for their patients.<sup>111</sup>

**35.83** Despite their obvious deficiencies, Dr Alexander thought that the early anti-HCV tests were a major breakthrough for clinicians in the management of HCV infection. Even the early kits with poor specificity and sensitivity were of considerable use in monitoring higher-risk groups (such as haemophilia patients, transplant patients and post-transfusion patients). In his evidence, he observed: 'if a patient was likely to be at risk of catching Hepatitis C, then the test was probably more valuable than in a patient who was picked randomly from the street who wasn't at risk'.<sup>112</sup> In his statement he noted: 'The correct approach to using the first generation tests was circumspection and careful review'.<sup>113</sup>

**35.84** Dr Alexander told the Inquiry what would happen to a donor who tested positive for HCV with the early assays:

If after 1991 a donor was found to be positive for HCV the donor was informed by the transfusion service and a recommendation was made to the general practitioner that the patient should be followed up by a hepatologist or a gastroenterologist with an interest in hepatology; for almost all transfusion centres in the UK at that time there was a list of named hepatologists who could be contacted.<sup>114</sup>

---

<sup>108</sup> Dr Alexander's statement on HCV testing [PEN.018.1360] at 1364

<sup>109</sup> Ibid [PEN.018.1360]

<sup>110</sup> Ibid [PEN.018.1360]

<sup>111</sup> Dr Alexander – Day 85, pages 117–118

<sup>112</sup> Ibid page 116

<sup>113</sup> Dr Alexander's statement on HCV testing [PEN.018.1360] at 1360

<sup>114</sup> Ibid [PEN.018.1360] at 1362

**35.85** Blood donors were tested prospectively. HCV-positive donors were only picked up if they returned to donate blood after the introduction of testing. At the same time people were discouraged from donating blood if they belonged to a 'high-risk group' (such as those who had a history, no matter how remote, of injecting drug use and practising homosexuals) for the safety of potential recipients, particularly following the AIDS period. As Busch had discovered in his review of HIV look-back in San Francisco, high-risk donor education programmes could lead to a dramatic reduction of infected donations as donors in high-risk groups self-deferred. Donors who had given blood in the past and were HCV positive and who did not attend after the introduction of screening in September 1991 (perhaps, high risk donors who had self-deferred) were not identified and neither were any of their corresponding recipients.<sup>115</sup>

**35.86** Dr Alexander's practice was to follow up donors with equivocal anti-HCV test results until third generation tests were introduced, at which point he explained that almost all of the patients in the group who had been followed up (nearly 200 at one stage) were found to be unequivocally negative for HCV and were no longer followed up.<sup>116</sup>

**35.87** Dr Alexander's account of the timetable of introduction of the successive stages of testing was challenged by Dr Gillon, who did not accept the section of Dr Alexander's report dealing with the use of first-generation tests in donor screening in September 1991. Dr Gillon said that he did not think that this was correct; he did not think that in any part of the UK a first-generation test was used at that stage.<sup>117</sup>

**35.88** As discussed more fully in Chapter 31, *The Introduction of Screening of Donated Blood for Hepatitis C*, a full test of second-generation kits was in operation in Scotland in the summer of 1991. Finance for the introduction of routine screening in English and Welsh regions was problematical. While on one view one can understand Dr Gillon's reservations, the position appears to be that some regions in England and Wales probably had not taken any steps to introduce screening at all, even on a research basis, prior to September 1991. Dr Alexander spoke from personal experience of the position in England and Wales and his evidence is accepted that, given the variation among regions in that part of the UK, first-generation ELISA tests were in use, at least in some regions, for up to 18 months after September 1991, notwithstanding that the second-generation test had become available in April 1991.<sup>118</sup>

**35.89** Scotland's position was privileged, not only in comparison with England and Wales, but internationally. In 1991 the USA was still screening with first-generation kits which had a high false positive rate.

**35.90** Dr Gillon noted that the screening and follow-up of the 200 individuals mentioned by Dr Alexander was carried out with an ELISA test and RIBA 'confirmatory' test, but without the benefit of PCR testing, which was developed in Scotland by Professor Simmonds. He explained that the RIBA confirmatory test could be very difficult to interpret; there was a category of results which was referred to in Scotland as 'indeterminate' where there might be limited evidence of positivity. The SEBTS did a lot of work with Professor Simmonds and some of these intermediate positives were shown to have a true positivity by PCR testing.

---

<sup>115</sup> Ibid [PEN.018.1360] at 1362 and Day 85, page 125

<sup>116</sup> Ibid [PEN.018.1360] at 1360

<sup>117</sup> Dr Alexander – Day 86, page 39

<sup>118</sup> Referred to in the chronology set out in the minutes of the meeting of the ACTTD ad hoc group on HCV antibody testing of blood donations held on 13 September 1991 [SNB.001.8919] at 8920. See also Day 86, pages 41–42

In Scotland, Dr Gillon's colleagues were able to 'drill' into the indeterminates using PCR. In England and Wales they would have simply remained equivocal. Dr Gillon agreed that, with the help of Professor Simmonds, his group was in a privileged position because they had access to PCR testing from 1991, in marked contrast to the position described by Dr Alexander.<sup>119</sup> Dr Alexander noted:

Around 1993 and 1994 the majority of centres with a particular interest in HCV infection had introduced PCR testing, often in house, to identify the presence of HCV RNA in blood and tissue. These were of variable quality and not available to all.<sup>120</sup>

**35.91** Taking the evidence of Dr Alexander and Dr Gillon together, it appears that Scotland had significant advantages over at least parts of England and Wales in September 1991 that would have been relevant to commencing look-back following the introduction of donor screening:

- All Scottish RTCs had access to second-generation ELISAs and RIBA confirmatory tests. In contrast, for up to 18 months after September 1991 some regions in England and Wales continued to be dependent on first-generation ELISAs and RIBA confirmatory tests.
- Highly effective PCR testing was available in south east Scotland in particular from the beginning of routine donor screening in September 1991 but PCR tests of variable quality only reached the majority of those centres in England and Wales that had a particular interest in HCV infection around 1993 and 1994.

**35.92** In using second-generation tests with ready availability of PCR testing, the SEBTS had exceptional technology, possibly unique in the UK, available to undertake look-back from the outset of donor testing in September 1991.

### **Scotland's ability to take unilateral action on look-back**

**35.93** Given the wide differences in the ability to implement look-back as described in the discussion so far, there was inevitably a question for the Inquiry as to whether Scotland could, and should, have proceeded to implement look-back at its own pace, irrespective of the difficulties English and Welsh colleagues might have experienced in following suit. As discussed below at paragraph 35.178, the legal position was resolved in December 1994 when Lord Fraser of Carmyllie, Minister of State at the Scottish Office covering home and health affairs, informed the Parliamentary Under Secretary of State at the DoH that, in the light of the medical and legal advice, he had little choice but to carry forward general look-back. His decision related to Scotland alone.<sup>121</sup>

**35.94** Lord Fraser of Carmyllie was Lord Advocate in 1991. He was succeeded by Lord Rodger of Earlsferry in 1992. It is extremely unlikely that, while the circumstantial context may have changed in the interval, the general principles on which legal advice available to Scottish Ministers was based would have changed between 1991 and 1994.

---

<sup>119</sup> Dr Gillon – Day 86, pages 39–41

<sup>120</sup> Dr Alexander's statement on HCV testing [PEN.018.1360]

<sup>121</sup> Lord Fraser's letter to Mr Tom Sackville MP dated 22 December 1994 [SNB.008.4848]

**35.95** Professor Cash stated that he was never prepared to accept ‘the notion that England can’t do it and therefore we can’t do it’.<sup>122</sup> He saw great advantages in ‘doing all sorts of things together’ when possible but said that ultimately it was up to Scottish Ministers to make the decision for Scotland, although he accepted that the decision of the Scottish Ministers would be based on advice from the SNBTS. He also accepted that at this point the SNBTS policy was not to institute a look-back programme.<sup>123</sup>

**35.96** There is a wider context that may have had a bearing on events. As discussed in Chapter 31, *The Introduction of Screening of Donated Blood for Hepatitis C*, at paragraphs 31.265–31.266, the demands for blood expected to arise from the first Gulf War had persuaded Professor Cash that anti-HCV testing could not begin until the Gulf conflict had ended or SNBTS personnel had shown that they could cope with the demands of the military and testing at the same time. Dr Gillon was a member of the committee working on preparations for the war. The SHHD had commandeered a hangar at Edinburgh Airport and his RTC was filling it with blood and making preparations for receiving wounded soldiers. He agreed that the opaque expression ‘national events’ might have been a reference to the preparations for the war.<sup>124</sup> The Gulf conflict, however, ended on 28 February 1991. At most it would have had an indirect, and reducing, impact on the capacity of the SNBTS to handle testing or look-back thereafter. Dr Gillon’s alternative explanation, that the expression in Professor Cash’s letter related to English reluctance to embark upon the programme in consequence of their resource difficulties, is more cogent.<sup>125</sup>

**35.97** There is no question as to whether Scotland *could* have proceeded unilaterally to implement Dr Gillon’s proposals, accepting that there was a compelling ethical obligation to inform patients who might have received infected transfusions. The critical question, whether the service *should* have proceeded with look-back before it did so, is considerably more complex. In the end, the advice Lord Fraser received relied on medical as well as legal factors. Dr Keel confirmed that Lord Fraser was given advice by policy colleagues, medical experts and legal advisors. This was the advice upon which he based his observation that look-back was no longer simply a matter of policy but of ‘legal liability’, and that it should begin as soon as possible in Scotland. The ability to treat patients became one factor among others. The decisions taken were clearly influenced by the actions Dr Gillon and his colleagues took following rejection of the proposal for general look-back. It is appropriate to discuss those actions first.

### **The south east initiative**

**35.98** The rejection of the proposal for a targeted look-back programme in parallel with the introduction of screening for anti-HCV was not welcomed by the transfusion service in the SEBTS and Dr Gillon in particular, as indicated by the evidence already noted.

**35.99** Dr Gillon could not remember precisely what discussions he had with Dr Brian McClelland, Director of the SEBTS, but he remembered saying to him, some time between March 1991 and the introduction of routine HCV testing in September 1991, ‘Right, I am going to be doing this [look-back] and I hope you will support it’, and that Dr McClelland

<sup>124</sup> Dr Gillon – Day 86, page 43

<sup>125</sup> *Ibid* page 29

said he would support it.<sup>126</sup> Dr Gillon could not recall whether this was formally fed back to Professor Cash and he had no record of either he, or Dr McClelland, having written to the Medical Director, although he did think that they would at least have had a conversation about their intentions. He could not recall any specific discussions with other SNBTS members about his plans but recalled that the matter was discussed at a meeting of the SNBTS Donor Consultants' Group.<sup>127</sup> He did not feel that he was 'hiding' the fact that he was intending to begin look-back in the SEBTS area.<sup>128</sup>

**35.100** Dr Gillon accepted that the whole idea of HCV look-back was a contentious issue at the time. He said that, before the start of screening in September 1991, look-back was an issue which was being debated by people in the blood transfusion community in the UK and internationally. He and his colleagues went to international meetings every year and the topic was frequently discussed. Other than a 'few relatively small countries', including the Netherlands, most countries appeared to be against the idea. Dr Gillon suggested that the reluctance on the part of the USA to introduce HCV targeted look-back was probably influential in this regard.<sup>129</sup>

**35.101** Between March 1991 and a symposium in Edinburgh on HCV in October 1993 (discussed below), the debate about targeted look-back was ongoing in the blood transfusion community. Dr Gillon thought that the debate probably took a back seat to some extent because the introduction of universal HCV testing of blood donations was a major preoccupation: the work of getting it in place, developing confirmatory procedures, dealing with false positives and counselling the patients who had tested positive would have kept people 'pretty busy'.<sup>130</sup>

**35.102** Dr Gillon confirmed that he took the decision to proceed with look-back in the knowledge that he would not be using a first-generation test.<sup>131</sup> Using second-generation tests alongside confirmatory PCR testing, it became apparent that the original estimate of 0.5–0.6% of donors who would require to be followed up was reduced to less than 0.1%.<sup>132</sup> There was confidence that, by that stage, if a virologist using PCR stated that a donor was HCV-positive it was likely that the diagnosis was correct. A paper published by Dr Gillon's group following the first six months' experience in south east Scotland reported 20 HCV-positive donors, a number considerably smaller than the less reliable first-generation tests would have produced.<sup>133</sup>

#### *Implementation of the south east initiative: donor call-up and counselling*

**35.103** Dr Gillon said that in September 1991 he simply went ahead with targeted look-back in his region, south east Scotland, an area encompassing Lothian, the Borders and Fife.<sup>134</sup> The procedure was much as described above for targeted look-back generally. Donors who had been identified as positive on screening were sent a standard letter. The wording was bland but it encouraged the donor to come to see Dr Gillon's group because they wished to get a second sample to confirm the initial test result.<sup>135</sup>

<sup>126</sup> Ibid page 32

<sup>134</sup> Dr Gillon – Day 86, page 43

<sup>135</sup> Ibid pages 55–56

**35.104** The initial testing was exactly the same as was being introduced throughout Scotland at the time. Every blood donation in Scotland was subjected to a (second-generation) ELISA test – a fully automated, rapid screening test. A sample of material from donations which were reactive in the screening test was sent to the Microbiology Reference Unit for further extended testing, including an ELISA test from a different manufacturer and a more sophisticated supplementary RIBA-2 test. The PCR test was also available, which looked directly for the genetic material of the virus and could resolve indeterminate cases with a very high degree of accuracy.<sup>136</sup>

**35.105** In the case of donors confirmed to be HCV positive who had previously donated before the introduction of screening, the look-back followed the available SNBTS data on previous donations. The first step was to identify what had happened to each of those previous donations: what components were made from them, where they were sent and what was known about their fate. Some of them would have been time-expired without being transfused, some would have been used for quality control purposes but most would have been sent to hospitals for clinical use.<sup>137</sup> Dr Gillon was assisted in this part of the exercise by Dr Yasmin Ayob. Seconded to the south east Scotland RTC from the blood centre in Malaysia, Dr Ayob was a haematologist moving into a career in transfusion medicine. She provided assistance in looking at medical records, identifying the date(s) of transfusions and identifying the consultant(s) to be written to.<sup>138</sup> She also helped Dr Gillon draft the preliminary report on the exercise around the end of 1992 and was the lead author of an article published in the journal *Transfusion* describing the SEBTS look-back exercise ('the Ayob paper').<sup>139</sup>

**35.106** Dr Gillon explained that for the purposes of 'recipient identification', the SEBTS had direct access to the majority of the relevant medical records because they were located in the Royal Infirmary of Edinburgh (RIE). The blood bank was under SNBTS control and Dr Gillon could obtain any patient's medical records within about 24 hours. This increased their workload in cases dealt with at the RIE. They were doing that part of the look-back exercise which, in other circumstances, would have been done by an outside hospital holding the blood bank. In cases where outside hospitals were involved, the hospitals were contacted through formal routes, informed of the facts and asked for details of the fate of the individual components: whether the component was still in stock or was time-expired and had been disposed of, or whether a patient had received it and, if so, whether the recipient patient could be identified. Dr Gillon's team would then receive a report back. Although, as noted, the arrangement in the south east region increased the workload for Dr Gillon and his team, having access to the majority of relevant medical records undoubtedly speeded up the process because certain vital information about the fate of the component and the recipient could be established from the hospital records in most cases.<sup>140</sup>

### ***Knowledge of the south east initiative***

**35.107** Professor Cash was unable to recall when he first found out that Dr Gillon was pursuing look-back independently in the south east region. He thought that it was probably at some point between 1992 and mid-1993 but speculated that it might have been even earlier than that.<sup>141</sup> Dr Gillon thought that he had informed Professor Cash of the look-back

<sup>138</sup> Ibid page 44

<sup>139</sup> Ibid page 51

<sup>140</sup> Ibid pages 56–58

<sup>141</sup> Professor Cash – Day 85, page 57

exercise at some point between March 1991 and September 1991.<sup>142</sup> Professor Cash could not remember if the SEBTS had started the look-back programme without reference to him or the MSC, but said that there came a point when the Directors of the SNBTS became generally aware of Dr Gillon's work. He was certain that he had become aware of the project, at the latest, by the date that the Ayob paper on the early experience in carrying out look-back was accepted for publication in November 1993. He recalled that it had been mentioned at an MSC meeting and that Dr Gillon was asked for a pre-publication copy.<sup>143</sup> However, Professor Cash made it clear that he would defer to either Dr Brian McClelland's or Dr Gillon's recollections on the question of when he was informed.<sup>144</sup>

**35.108** Although Professor Cash said that the study was not 'secret', he recalled that it was his suggestion, when it became known, that it should be called a 'pilot' or 'feasibility' study so as not to 'ruffle any feathers'.<sup>145</sup> He accepted that, in point of fact, when Dr Gillon's study started it was not a pilot scheme but his reaction when he first heard about Dr Gillon's work was that he was 'a little nervous' because he knew that there was opposition to the whole idea of look-back in some quarters, stating that there were 'vast amounts of sensitivity lurking around in government circles' about look-back. He thought that, if the SNBTS wanted to roll out what had been going on in Edinburgh to other parts of Scotland, they would need the support of Ministers and CMOs. It seemed to him that the best approach to describing what had been going on in Edinburgh was to label it a 'pilot scheme'.<sup>146</sup>

**35.109** Dr Gillon thought that the scheme was first labelled as a 'pilot scheme' either by himself and Dr McClelland together or by Professor Cash, with or without input from the pair of them. However, he noted that Professor Cash would not have so labelled the scheme unless they knew this was to happen. Dr Gillon was not unhappy to call it a 'pilot study'. He recalled, however, that at a meeting he referred to it as the 'SNBTS pilot study' and was sharply reprimanded by Professor Cash who said it was not to be regarded as the 'SNBTS' pilot study. Dr Gillon considered that Professor Cash had said that, either because he did not want to be personally associated with the exercise or because he felt that it had the potential to damage the reputation of the SNBTS. Dr Gillon was happy to go along with that as well and refer to it as the 'South East Scotland pilot study'.<sup>147</sup> He noted that on instituting look-back he had expected that he might get into trouble with Professor Cash, and that he had not anticipated that it would all go 'swimmingly'.<sup>148</sup>

**35.110** Mr McIntosh introduced his involvement with the look-back exercise by explaining that he took a 'relatively backseat' position at the time. He went on to say that this was mainly because he considered it:

[O]ne thing that my Medical and Scientific Committee could simply absolutely be trusted to take responsibility for. So my involvement with it was very much ... I was overseeing it ... it happened on my watch. I was responsible for doing certain things to make sure that it went smoothly.<sup>149</sup>

<sup>144</sup> Ibid page 61

<sup>145</sup> Ibid page 54

<sup>146</sup> Ibid pages 58–60

<sup>147</sup> Dr Gillon – Day 86, pages 51–52

<sup>148</sup> Ibid pages 47–48

<sup>149</sup> Mr McIntosh – Day 84, page 75

**35.111** So far as the SEBTS initiative is concerned, it appears to be clear from Mr McIntosh's evidence that he had little idea of what was going on at the time. At some stage he came to understand that it was described as a 'pilot study'. Shown Dr Gillon's evidence on the establishment of his working group and the way look-back was initiated in September 1991, he realised that he had misunderstood the nature of the exercise. It had not, as he had understood at the time, begun as a pilot study and later 'became a reality'.<sup>150</sup> In any event, if his evidence as a whole were to be accepted, it would not be possible to find that he did understand the background to Dr Gillon's actions in 1991 or the true nature of the look-back exercise when it was implemented. He speculated that in the light of what had happened when Newcastle began screening for Hepatitis C before the date agreed for the UK, the clinician responsible being 'practically hounded out of the profession' for it, Dr Gillon would have had good reason for his exercise having a low profile. Further, he would be concerned that the exercise should not be stopped, which Mr McIntosh thought might have been a possibility if its true nature had been disclosed.<sup>151</sup>

**35.112** Professor Cash could not recall what he told Mr McIntosh about Dr Gillon's programme but asserted that they did have regular briefing meetings, usually every week, and said that at the meetings anything 'that was on the go', would be discussed with Mr McIntosh. He felt that he must have told Mr McIntosh about Dr Gillon's work and was surprised to hear that, when Mr McIntosh gave evidence, he had said that he had not realised that it was not a pilot scheme at the time.<sup>152</sup>

**35.113** Unfortunately, there are no records available to cast any additional light on this matter. Given the sensitivity of the project, as adverted to by Professor Cash, it may be that his description of it, before it became known as a 'pilot study', was less clear than he subsequently remembered. Whatever the precise explanation for this difference in the evidence, Mr McIntosh's assertion that he did not know about the study until after it was described as a 'pilot study', and even then did not fully understand the nature of the exercise, is accepted.

### *Publication and reaction*

**35.114** The published report of the first period of study showed that screening took place between 1 September 1991 and 29 February 1992, when 42,697 donors were screened routinely.<sup>153</sup> Twenty donors were identified as HCV-positive, 15 of whom had given around 63 previous infected donations among them.

**35.115** Because some of the individuals who were identified had been donating for many years, the number of components was not inconsiderable – 83 in total from the 63 infected donations – but it was considered to be manageable. All of the recipients of infected components still alive, nine in total, were found to be HCV-positive. Dr Gillon said that it was a bit surprising that his group found so few recipients of infected blood or components who were alive, even at that stage of their investigations, having started look-back as rapidly as possible. Before starting the look-back they did not have any indication as to how many positive donors would turn up.<sup>154</sup>

<sup>153</sup> Ayob et al, 1994 [LIT.001.3802]

<sup>154</sup> Dr Gillon – Day 86, page 53

**35.116** Dr Gillon thought that the paper helped to answer the question as to whether targeted look-back should be pursued nationally. He felt that it at least gave it 'a nudge' and that it must have been one of the factors that revived discussion about look-back at the various committees.<sup>155</sup> In the discussion section of the paper, it was estimated that around 3300 patients might be alive and infected with HCV as a result of transfusion in the UK. Dr Gillon explained that the extrapolation was based simply on what was known about the prevalence of Hepatitis C in the donor population from the first six months of testing. This gave a figure of roughly 300 for Scotland and 3000 for the rest of the UK.<sup>156</sup> The report concluded by saying: '[T]his problem should not be ignored on logistical grounds when, in each case, there is an overwhelming responsibility to the individual patient'.<sup>157</sup>

**35.117** Dr Gillon also referred to the finding that no recipient was alive and traceable more than five years after transfusion. Dr Gillon said that this very important finding confirmed that if one were to go back more than five years there would not be many patients at all who were still alive to be found. Broadly speaking, he considered that this would support the argument that look-back should be started as soon as possible: if there was a chance to do anything about it, it was necessary to identify the patients sooner rather than later.<sup>158</sup>

**35.118** The methodology adopted by the SEBTS would probably not have been feasible in the west of Scotland for logistical reasons.<sup>159</sup> The advantages that the SEBTS possessed, in comparison to other regions, were that the majority of the records they required to consult were housed in one location in the Royal Infirmary of Edinburgh; they had excellent IT available; and the blood bank was under their control. In addition, they had Dr Ayob's services. The practical difficulties in the west of Scotland region are discussed in greater detail below. However, the SEBTS experience clearly demonstrated the feasibility of targeted look-back in general terms.

### The workshop on HCV

**35.119** Until the early 1990s, there was no treatment for HCV infection that was thought to be effective. Until such treatment became available, there was an ethically sustainable argument that it was inappropriate to tell patients that they had been, or may have been, infected, given that there was nothing that could be done to deal with their infection. However, as Dr Gillon pointed out, by the stage at which he proposed look-back there was already a body of evidence that Interferon might give some beneficial results. It was noted in the fourth and, it appears, final draft of the guidelines that: 'Progressive chronic hepatitis C has been treated successfully with Interferon, and though this treatment is at present experimental, it holds out considerable promise for the future'.<sup>160</sup> There was also available a paper, from Makris and others in the north of England, about Interferon treatment.<sup>161</sup> Research into treatment was a continuing concern of the pharmaceutical industry.

<sup>159</sup> Ibid pages 58–61. With the exception of the RIE, Ninewells Hospital, Dundee, Aberdeen Royal Infirmary, Raigmore, Inverness, and Law Hospital, where there were SNBTS administered blood banks, blood banks were invariably located in hospitals' haematology departments and the SNBTS did not manage them. Tracing a component involved the consultant haematologist in charge of the blood bank and through that officer the clinician responsible for the patient's treatment. See more detailed discussion below at paragraph 35.129 onwards.

**35.120** A workshop on HCV infection was held at the Royal College of Physicians of Edinburgh in October 1993. It had been arranged by Professor Cash. Among the speakers was Dr Geoff Dusheiko of the Royal Free Hospital, London, who gave a talk on the latest information about treatment for HCV. In retrospect, Dr Dusheiko was one of a small group of doctors claiming cure rates for Interferon which turned out later to be somewhat optimistic. However, the perception that there might be an effective cure was important in shaping opinion, and his views were relevant at the time. Asked whether he remembered, broadly, the contents of Dr Dusheiko's address, Professor Cash stated:

No, I don't but I have the memory, which may be purely spurious and something that is thought up for my convenience: I think he harangued us .... And I am almost certain in my mind – I don't have any records of this – he actually said "You should be look-backing".

Professor Cash was 'pretty sure' that he had spoken with Dr Dusheiko before the workshop and told him that, if better treatment for HCV was becoming available, he should 'plug' look-back.<sup>162</sup>

**35.121** Professor Cash's recollection was that Dr Dusheiko also strongly recommended instituting HCV look-back programmes. He said that it was at this point that, having been enthusiastic about look-back from the start, he now felt that the SNBTS 'could now really pursue this very hard'.<sup>163</sup>

**35.122** Dr Gillon also attended the workshop and presented a paper entitled 'Epidemiology of Hepatitis C'.<sup>164</sup> Although he was mainly concerned with broader epidemiological issues, setting out what was known about the patterns, causes and effects of HCV for a largely non-specialist audience, Dr Gillon said that a relatively small part of his talk was concerned with his experience of look-back in the south east of Scotland. The transcript of the proceedings noted that there was a discussion after Dr Gillon presented his paper but he said that nobody asked a question about the look-back exercise. Dr Gillon stated that Dr Dusheiko did not refer to look-back in his talk and that the question of look-back did not come up in the discussion after his presentation either. It was his view that after the topic had been aired it had interested Dr Dusheiko 'and maybe one or two others there'. He recalled that Dr Dusheiko was interested in the topic from a clinical standpoint, and asked 'why isn't this happening?'.<sup>165</sup>

**35.123** Initially, Professor Cash recalled that Dr Gunson had attended the Edinburgh HCV workshop and had stayed overnight at his home afterwards. He also recalled being in the lecture theatre with Dr Dusheiko, by the lectern, and shouting to Dr Gunson 'come over here'. He said that Dr Gunson was 'extremely anxious' about the position taken by Dr Dusheiko. Professor Cash regarded the workshop as a watershed moment in the development of his thinking about look-back and decided that, 'We [the SNBTS] are just going to press on ourselves and see where it takes us and I'll keep Harold informed but you are on your own, Harold'. He told Dr Gunson of his decision that evening. Professor Cash was somewhat reluctant to describe Dr Gunson's reaction but said that 'the body language wasn't happy ... I think he knew in his heart they [the NBTS] couldn't deliver'.<sup>166</sup>

<sup>165</sup> Dr Gillon – Day 86, pages 70–72

<sup>166</sup> Professor Cash – Day 85, pages 85–86

**35.124** Professor Cash was referred to a letter he wrote to SNBTS Directors dated 15 October 1993 following the workshop. The letter stated:

One of the outcomes of the recent HCV Symposium ... was that there is a need to refer patients who have recently acquired HCV infection to specialists for consideration as to whether they should have early interferon therapy.

I do believe this places an obligation on the BTS to use its best endeavours to advise clinical colleagues accordingly when we have evidence that a recipient may have acquired HCV.<sup>167</sup>

It appears that the relevant 'outcome' relates to Dr Dusheiko's advocacy of Interferon therapy, strengthening the case for reverse look-back. But it does not help resolve the question whether Dr Dusheiko spoke in favour of targeted look-back in the course of his presentation (as Professor Cash maintained) or, as Dr Gillon suggested, only after the formal presentations and the discussions following thereon had finished.

**35.125** Dr Keel also attended the workshop. Unfortunately, she had little memory of the event. She said that she was aware of developing interest in emerging treatment using Interferon and the idea that clinicians might at some point be able to offer treatment to patients, although she noted that it was by no means universally accepted that it was an effective treatment, with experts such as Professor Zuckerman expressing doubts.<sup>168</sup> Dr Keel assumed that she had attended the morning session of the workshop and remembered Dr Dusheiko talking about treatment during the afternoon session, but could not remember the details of his presentation. She had no memory of Dr Gillon's talk and had no recollection of data from the pilot study being made available at the symposium. She was referred to the text of Dr Gillon's presentation and accepted that it was describing a look-back exercise but still had no recollection of it.<sup>169</sup> She had no clear recollection either of any details about the SEBTS look-back exercise nor of any renewed emphasis being given by Professor Cash and his colleagues to the need to institute look-back by October 1993.

### **A change of direction: Medical and Scientific Committee meeting on 9–10 November 1993**

**35.126** The MSC met on 9 and 10 November 1993.<sup>170</sup> Dr Mitchell, Dr McClelland, Dr Perry and Professor Cash were all present. Dr Keel was present for certain agenda items only, including item 4.6.4 headed 'Look-back HCV'. Professor Cash said that it was felt to be very important that Dr Keel was present at this meeting because, if the SNBTS wanted to take look-back forward effectively, they would have had to engage with the Scottish Office who would be advising Ministers.<sup>171</sup> He explained in oral evidence that putting look-back on the agenda was an attempt at 'upping the ante'. He considered that his new attitude to look-back had been affected by the positive response he got from colleagues at the SNBTS to his letter of 15 October.<sup>172</sup>

---

<sup>167</sup> Professor Cash's letter to SNBTS Directors dated 15 October 1993 [SNB.005.2107]

<sup>168</sup> Dr Keel – Day 86, page 116

<sup>169</sup> Ibid pages 118–120

<sup>170</sup> Minutes of meeting of the SNBTS Medical and Scientific Committee on 9 and 10 November 1993 [SNB.009.9176]

<sup>171</sup> Professor Cash – Day 85, page 74

<sup>172</sup> Ibid pages 75–76

**35.127** Professor Cash said that he could not remember the discussion at the meeting in detail. However, he was clear that he was arguing that the position on look-back had changed and that the SNBTS needed to begin to think about it more seriously. He was advocating look-back 'right across the board' rather than just the Edinburgh 'feasibility study'.<sup>173</sup> He thought that Dr Crawford had already determined that the SNBTS could not implement look-back<sup>174</sup> because he was extremely anxious at the size and the nature of the problem raised by such a programme.<sup>175</sup>

**35.128** Professor Cash said that he considered that this was the time to come up with 'a firm policy proposal' although after great discussion it was decided that it 'wasn't quite appropriate'.<sup>176</sup> The minute of the meeting noted:

After a full discussion in which the principles of lookback of HCV PCR positive donor archive samples and appropriate communication with recipient's GPs were agreed, it was felt that the position concerning PFC products required further consideration. The Committee felt it would be inappropriate to make a policy decision at this time and that further discussion was required.<sup>177</sup>

Among the documents recovered by the Inquiry was an action log following the meeting which indicated that Professor Cash was to ensure that 'look-back-HCV' received further discussion.<sup>178</sup>

**35.129** Although he could not recall why a policy decision was not made at that point, he speculated that it would be because other regions – Inverness, Aberdeen and Dundee but particularly the west of Scotland – would have had concerns about the difficulty of implementing look-back and would have been asking to see the 'nuts and bolts' of what had been going on in the south east region before agreeing. Professor Cash explained that Edinburgh was 'hugely well resourced'. They had a superb IT programme for the blood-bank and, in practical terms, Dr McClelland and Dr Gillon had control of over 70% of all of the clinical cross-matching in the south east of Scotland.<sup>179</sup> As in that region, in Dundee, Aberdeen and Inverness the RTCs dominated the 'clinical interface' with blood transfusion. This was not the position in the west of Scotland.

**35.130** Professor Cash said that Dr Mitchell, Director of the West of Scotland, 'didn't have a thing such as a blood bank' in the way other centres did.<sup>180</sup> In Glasgow, the Royal Infirmary, the Western General Hospital and Stobhill Hospital each had departments of haematology with their own blood banks. These blood banks were supplied with blood by Dr Mitchell from 'a chilled warehouse in the West of Scotland', but the blood was not attached to any patient at that stage. Requests for blood in Stobhill, the Royal Infirmary Ayrshire and Fort William, for example, came in from clinical units to the local blood bank and were dealt with locally.<sup>181</sup> Glasgow BTS had no blood banking IT system because they did not have overall responsibility for blood banking.

<sup>180</sup> Ibid page 79. This was a slight exaggeration since Dr Mitchell had administrative control over Law Hospital's blood bank; but in practical terms it was true for the region taken as a whole.

<sup>181</sup> Professor Cash – Day 85, pages 81–82

**35.131** If HCV look-back were to be introduced in the west of Scotland region, Dr Mitchell would have had to rely on ‘first trigger information’ about possible transmission of infection generated from a very wide geographical area. Information about infective donations would have come from locations as far apart as Oban and Ayrshire and Fort William and central Glasgow, a widespread geographical area over which he had no effective overall control. This led to anxiety about ‘rushing to a policy’, particularly in the west. Despite the fact that screening had started in September 1991, in operational terms, if there was a look-back policy to implement, it was felt that things were going to have to be done suddenly.<sup>182</sup>

**35.132** Although not specifically minuted, Professor Cash stated that these concerns would have been ‘ventilated very effectively’ at the meeting in November 1993.<sup>183</sup> Despite the outcome, Professor Cash said that by the end of the meeting his attitude was to keep going with trying to implement look-back throughout Scotland. A note in the minutes stated that Dr McClelland was to circulate look-back information.<sup>184</sup> This was an early copy of the paper relating to the Edinburgh feasibility study and was to be provided to assist colleagues ‘to get a feel as to what was involved’.<sup>185</sup> Professor Cash explained that he wanted the Edinburgh document to be taken back to the west of Scotland BTS to be read and talked about in order to begin to put together a picture of how things might proceed there. He felt by that stage that ‘as night follows day,’ look-back would be implemented. Now that HCV treatment was available, the SNBTS was reaching a point where they had ‘a total moral obligation’ to implement look-back and the question now was how they were going to do it. At the back of his mind was that ‘the Edinburgh way might not be the best for the likes of the West of Scotland’.<sup>186</sup> In fact, Dr Ewa Brookes in Dundee had, since the inception of screening in 1991, also been attempting to follow up donations given by HCV positive donors who had donated prior to screening, in order to try and trace their recipients. Dr Keel recollected attending the meeting but said that although look-back was on the agenda, along with many other matters, she had no recollection of any emphasis being given by Professor Cash and his colleagues to the need to get on with look-back and was certain that no details of the SEBTS feasibility study had been revealed at that stage to her. She also did not recall getting any written information after the meeting from Brian McClelland and thought that its lack might explain why, when details of Dr Gillon’s exercise had subsequently been provided to her, it had been such a revelation.<sup>187</sup>

**35.133** Professor Cash was referred to a letter he had written to Dr Gunson on 18 November 1993.<sup>188</sup> The letter commented briefly on the Edinburgh symposium in terms suggesting that Professor Cash was providing information about the proceedings. Coupled with the fact that he did not refer to Dr Gunson having attended the symposium in the letter, Professor Cash came to doubt whether Dr Gunson actually had attended the symposium.<sup>189</sup> Leaving aside the doubt cast on Professor Cash’s recollection, the letter stated, with reference to the MSC meeting: ‘colleagues stepped back from introducing a look-back policy until such times as further (UK) deliberations had taken place’.

<sup>188</sup> Professor Cash’s letter to Dr Gunson dated 18 November 1993 [SNB.005.5560]

<sup>189</sup> Professor Cash – Day 85, pages 87–88

**35.134** The letter was copied to Dr Mitchell and Dr Perry who sat on the ACVSB/MSBT. It was also copied to Dr Keel. The letter stated: 'It occurred to me that it might be appropriate for the item to be researched for, and discussed by, MSBT. I would value your comments and support'. Professor Cash explained that his intention in writing the letter and copying it to these recipients was to speed things up by encouraging the ACVSB/MSBT to advise Ministers to proceed with look-back. He was not in a position to insist, without ACVSB/MSBT support, that look-back should proceed.<sup>190</sup> As noted above, Professor Cash thought that actually delivering look-back would have required the Chief Medical Officer (CMO) or the Department of Health or Ministers to instruct health board doctors to work closely with their local transfusion service to undertake look-back. He considered that it required that level of authority and that many people shared his view. He noted that there were some clinicians who were 'not very collaborative' and several claimed they 'were far too busy'. If people were not prepared to go and find records of transfusion practice because it was a lot of extra work, it 'required a CMO ... to say "I'm instructing, in the name of the minister, that you go and do it"'. Professor Cash considered that the easiest way for the SNBTS to have look-back implemented would be for the ACVSB/MSBT to say, 'We think the time has come [for look-back], let's go'. That would have been 'immediately flashed to the Scottish Office and something could have happened'. He considered that would have been a 'great comfort' to Dr Mitchell's team.<sup>191</sup> If the decision had been reached at Ministerial level, securing the extra resources to implement a programme would have been easier.

**35.135** The matter was also raised by Professor Cash at the meeting of the ACTTD/I on 18 January 1994.<sup>192</sup> He noted Dr Dusheiko's advocacy of look-back on the grounds of the potential benefits of Interferon treatment, especially if initiated early in the course of infection. The minutes noted support only for the concept of look-back and encouraged 'grant seeking for this potentially clinically beneficial undertaking'.<sup>193</sup> Various members of the committee were to look into the issue further and report back at the next meeting.

### Issues Meeting on 16 May 1994

**35.136** An 'Issues Meeting' attended by members of the SNBTS and the Scottish Office was held on 16 May 1994.<sup>194</sup> Dr Keel explained that Issues Meetings were set up with a view to providing a forum for discussion of issues of mutual concern. She commented that, in 1994, while Issues Meetings were more sporadic than they are today, they were not ad hoc meetings in response to specific events. They would take place when policy colleagues felt that there was enough on the agenda to make a meeting worthwhile.<sup>195</sup> Professor Cash agreed that Issues Meetings were very infrequent.<sup>196</sup> The SNBTS personnel in attendance on 16 May 1994 were David McIntosh, Dr Perry, Dr McClelland and, from the Scottish Office, Dr Keel, Dr Young and Mr Tucker. Dr Gillon was not present.

**35.137** Dr Keel said that, from the time she joined the SHHD up until the beginning of 1994, her sense of the general attitude at the SHHD to implementing look-back was that 'we shouldn't be proceeding with it because ... it wouldn't be feasible and ... there was

no really evidence-based treatment which would be effective for individuals identified with the virus'. According to her evidence, the SHHD view was informed by the SNBTS' view but also more widely by the view which had been expressed by committees south of the border, in particular the ACVSB/MSBT, and by expert opinion across the UK and abroad.<sup>197</sup>

**35.138** Dr Keel said that prior to the Medical and Scientific Committee (MSC) meeting on 18 May 1994<sup>198</sup> she did not know that there had been a look-back exercise going on in Edinburgh and south east Scotland.<sup>199</sup>

**35.139** At paragraph 13 of the minute of the 16 May Issues Meeting, it is recorded that HCV look-back was discussed:

Mr McIntosh indicated that when HEP C testing of donations was introduced in 1991 it was not thought appropriate to look back over previous donations. Mr Panton confirmed that any claims for compensation following infection with Hepatitis C should be refuted. After discussion it was agreed that Mr McIntosh would send a draft policy statement about look back to the Department for clearance. This would be used in any newspaper/media enquiries received by SNBTS. (Following further developments after the meeting a meeting was arranged for Tuesday 24 May to discuss SNBTS look back proposals).<sup>200</sup>

**35.140** Dr Keel was referred to the comment that Mr McIntosh would send a draft policy statement about look-back to the department 'for clearance'.<sup>201</sup> She had no strong recollection of a discussion about look-back although clearly it was discussed. Her clearest recollection of Dr Gillon's work was at the meeting two days after this at the MSC. Despite Mr Panton's comments about refuting claims for compensation, she did not consider that it was a major element in the department's thinking about why look-back should not go ahead. Their attitude was then based on a lack of effective treatment, logistical difficulties and lack of feasibility. Directed to the passage about media interest, she said that she had no memory of any particular media interest in look-back at that stage and was not aware from where it might have come or what might have stimulated it. At the time Dr Keel left the meeting she did not think that look-back was a 'particularly hot issue'.<sup>202</sup> In his evidence Dr Gillon noted that in the 'early part of 1994' stories were beginning to appear about it in newspapers, and that the *Sunday Mail*, or one of the Scottish papers, made it 'into a bit of a crusade'.<sup>203</sup>

**35.141** In contrast to Dr Keel, Professor Cash said that he thought that the link between the look-back programme and compensation was 'chronically there'. The whole concept of liability and compensation 'lurked around in [his] memory' all the time.<sup>204</sup>

### Medical and Scientific Committee meeting on 18 May 1994

**35.142** The MSC met on 18 May 1994.<sup>205</sup> The agenda for the meeting did not include the topic of look-back.<sup>206</sup> The action log, attached to the agenda, recorded that look-back HCV was then 'being discussed' by the ACTTI.<sup>207</sup> Both Dr Keel and Dr Gillon were present. Under Any Other Competent Business 1, sub-heading, 'HCV lookback', the minutes set out elements of the procedure to be followed on finding a 'known' (that is, return) donor who tested anti-HCV positive.<sup>208</sup> These related to re-testing archived samples and follow-up steps. It was agreed that the procedure would be based on an outline in the forthcoming publication in *Transfusion* of Dr Gillon's protocol (the Ayob paper) and Dr Gillon was to circulate a pre-publication copy.

**35.143** In terms of follow-up procedure, the minute stated:

v. From a SHHD perspective, [Dr Keel] expressed a view that the SHHD may not have a locus in this matter and that the SNBTS should make a decision on lookback for HCV that was based on their professional judgement. However, before SNBTS took any action [Dr Keel] asked to be given the opportunity to discuss the issues with SHHD colleagues to seek their views and asked that the SNBTS take no formal action until she had subsequently contacted [Professor Cash].

vi. Once [Dr Keel] had communicated the SHHD position to [Professor Cash] and provided SHHD were in agreement that the SNBTS should implement this policy, [Professor Cash] would write to [Mr McIntosh] to provide details of the SNBTS policy, thereby allowing a decision to be taken on a starting date for the process. [Professor Cash] also would formally advise NBA, NIBTS, SACTII and MSBT of the SNBTS policy.

vii. If SHHD agreed that SNBTS should develop and implement a lookback policy for HCV, [Dr Keel] subsequently would communicate this to DOH.<sup>209</sup>

**35.144** Professor Cash's recollection was that Dr Keel was invited along specifically for the look-back discussion.<sup>210</sup> Dr Keel disagreed: she said that it was normal for her to attend MSC meetings; she wouldn't necessarily always be there for the whole event but she would attend for part of the meeting depending on other diary commitments. She would look at the agenda in advance to decide which parts of the meeting to stay for. Generally, she tried to be there at the beginning and stay for as long as she could.<sup>211</sup>

**35.145** Notwithstanding the minutes, there were widely differing impressions of the proceedings at the meeting. Professor Cash considered that the Directors were saying 'we have had enough of procrastination, it's go for it time' and that this was 'game, set and match'. He felt it was a hugely important meeting because Dr Keel had expressed the view that the SHHD 'may not have a locus' with regard to look-back and that the SNBTS should make a decision on look-back for HCV based on their professional judgement. He

<sup>208</sup> Minutes of meeting of the SNBTS Medical and Scientific Committee on 18 May 1994 [SNB.009.9331] at 9335

<sup>209</sup> Ibid [SNB.009.9331] at 9336

<sup>210</sup> Professor Cash – Day 85, pages 95–96

<sup>211</sup> Dr Keel – Day 86, pages 122–123

explained that most of the SNBTS people ‘fell off our seats’ when they heard Dr Keel say that. They were unaccustomed to such language and, indeed, Professor Cash recalled that they had gone through a pretty painful process of instituting donation testing for HCV, when it was made ‘absolutely clear’ to them that the professionals could not decide themselves whether they would start testing and when they would start testing. He had assumed that the same was going to apply to HCV look-back and that it would be Ministers that would say to the Scottish transfusion service that they could ‘go ahead and do it now’. The SNBTS representatives were surprised that it might be left to them.<sup>212</sup> Dr Keel, the representative of the Scottish Office, now seemed to be saying, ‘that’s ok but ... before you do anything, let the department have just some consultation’ but that once the SNBTS’ ‘masters [that is, the Scottish Office] had spoken’ they could proceed to inform everybody what they had been told to do.<sup>213</sup> He agreed with the suggestion that the SNBTS ought to ‘touch base with the Scottish Office’ and believed that agreement on that had been reached at the meeting.<sup>214</sup> From his perspective, Professor Cash believed that by the end of the meeting the main issues to be resolved were the practicalities of introducing look-back in Scotland generally.

**35.146** Dr Keel thought that if Professor Cash had indicated to her before the meeting that the SNBTS now wanted to go ahead with the look-back exercise, she would have spoken to policy colleagues before she attended it as that would have constituted a considerable change in the SNBTS’ view on look-back. She explained the reasons why the Scottish Office (and the UK Government generally) did not want to proceed with look-back, and that was the policy which was in her mind before attending the meeting. If she had been given advance notice that the SNBTS was going to present her with evidence that suggested that it should be moving towards look-back, she thought it would have been obvious to her that she should have discussed it with policy colleagues in advance. No decision in government is ever taken unilaterally; decisions are corporate and advice is developed by a number of people before approaching Ministers. As far as she was concerned it would not have been the SNBTS’ decision to proceed unilaterally with look-back.<sup>215</sup>

**35.147** Dr Keel said that, at the meeting, Dr Gillon’s report had demonstrated that look-back was feasible. Although it was not minuted, she recalled that Dr Gillon gave a presentation at the meeting which, for the first time that she could remember, very explicitly laid out how he had gone about look-back in the south east region, how many people had been identified and how successful they had been in tracing recipients of blood and blood components derived from infected donors.<sup>216</sup> Her recollection was that Dr Gillon’s presentation provided convincing evidence of the feasibility of undertaking a look-back exercise and of tracing infected donations to recipients, and made a powerful impression on her.<sup>217</sup> She became conscious of what had been going on: as far as she was concerned, this was new evidence that she needed to discuss with her colleagues. She felt that it was really a clinical judgement as to whether to go ahead with look-back. Although the SNBTS would need help with organising look-back, in ‘purely professional terms’, they had identified that they could do it and they were already identifying recipients of blood

<sup>217</sup> Ibid page 130. The Ayob paper was accepted for publication on 21 July 1994. It was clearly available to SNBTS Directors by November 1993 at the latest. It appears on her evidence that Dr Keel cannot have seen it by May 1994.

that was infected (in the south east region) and therefore had a duty of care to those individuals. She explained that that was why she said that the 'SHHD may not have a locus in this matter and that the SNBTS should make a decision on lookback for HCV that was based on their professional judgement'.<sup>218</sup> At the meeting the MSC suggested that look-back should be pursued. Despite what Dr Keel said at the meeting about the SHHD not having a locus, she accepted that the SHHD did in fact have a locus in the matter of look-back and that one of the reasons that she said what she did was because she was relatively new in her post.<sup>219</sup>

**35.148** She did not agree that the minutes were accurate in noting that Professor Cash would inform the ACVSB/MSBT of a change of SNBTS policy on look-back. She would have expected him to use the SHHD or one of the SNBTS members of the ACVSB/MSBT to convey the SNBTS change in view rather than doing it directly himself.<sup>220</sup> She had a recollection of someone from the SNBTS saying to her that Professor Cash was planning to phone Dr Gunson to pass on the views that she had expressed in the meeting and that the SNBTS would be going ahead with the look-back. At that point she thought she had better get back to St Andrew's House to discuss this with policy colleagues as a matter of urgency. She thought that Professor Cash was proposing to tell Dr Gunson that the SHHD had said that the SNBTS could go ahead with look-back and therefore look-back would be happening in Scotland.<sup>221</sup> Dr Keel felt that this was not correct, however, and that her view was reflected in the minutes which, indeed, noted that the SNBTS was to 'take no formal action' until Dr Keel had discussed the matter with her colleagues and spoken again with Professor Cash.<sup>222</sup> By the end of the May meeting, Dr Keel considered that it had been agreed that the SNBTS would wait until she had conferred with colleagues before confirming their policy on look-back.<sup>223</sup>

**35.149** It appears that Dr Gillon's presentation had made a great impression on Dr Keel. She explained that, when she left the meeting, she was convinced that it was now her job to convince policy colleagues that the right thing to do was to implement look-back. Dr Gillon's pilot had demonstrated its feasibility. She was also aware that treatment was now available for infected patients. She accepted, further, that the implication of the fact that look-back was feasible was that there might be some legal liability on grounds of duty of care.<sup>224</sup>

**35.150** Dr Keel had personally been persuaded. When she returned to St Andrew's House she discussed the question with Mr Panton. Her recollection is that both of them then went to speak to Mr Panton's senior, Mr George Tucker, and they then had a collective discussion.<sup>225</sup>

**35.151** At some time after this discussion, they sought legal advice on the issue of liability. The date on which they approached Scottish Office solicitors for advice is not known. Although the relevant files relating to that period were not available, her recollection was that Mr Panton organised obtaining the legal advice. Similarly, she did not know who provided the advice but Lord Fraser's letter (discussed below at paragraph 35.178)

referred to it and Dr Keel spoke about it at the ACVSB/MSBT Committee. It follows that at some time between May and September 1994 she had obtained legal advice which would have come to her from a Scottish Office solicitor. Her recollection was that the advice was that, having demonstrated the feasibility of look-back, Scottish Ministers would be vulnerable if the programme was not extended across the country.<sup>226</sup>

### **Start/Stall**

**35.152** As anticipated at the Issues Meeting on 16 May, (paragraph 35.139 above) there was emerging media interest. Dr Gillon noted that there were various media campaigns going on around the time that the decision was taken to start, and that the headlines that appeared were 'really quite toxic at times and damaging to the reputation of the Transfusion Service'. On 19 May 1994, Mrs Mairi Thornton, National Donor Services manager, sent an internal memo to the SNBTS board, the CSA and others. It stated:

As you may know there has been media interest in Hepatitis C. The following paper confirms our agreed position and the information is being made available to the Sunday Mail which is running an awareness campaign on Hepatitis.<sup>227</sup>

**35.153** The paper, dated 18 May 1994, included the following:

6) Until very recently there has been no treatment known to provide an effective cure [for Hepatitis C] and there was thought to be little benefit in the early identification of the virus in any particular individual. Therefore when routine anti Hepatitis C testing of blood donations was introduced in 1991, it was not judged medically appropriate to seek out those few patients who might have contracted the virus from a blood transfusion in the years before testing was introduced.

7) However, the BTS has kept this policy under review. Recent clinical trials now suggest that beneficial treatment for some patients with acute hepatitis C may be a possibility. The Service is, in consultation with medical colleagues, assessing if any benefits might be gained from a 'look-back' exercise.<sup>228</sup>

**35.154** David McIntosh sent Mr Panton a faxed letter dated 19 May 1994.<sup>229</sup> It stated that the MSC 'has now formally recommended to me that the Service should implement a look-back policy without delay'. He commented that he was satisfied that the medical and scientific reasons for this, combined with good ethical and legal arguments, as well as obvious public relations implications, gave him sufficient grounds for the immediate acceptance of the MSC's recommendations, and said: 'I would therefore intend to give colleagues in England, Wales and Northern Ireland prior warning of our intentions and to activate look-back with effect from 1 June 1994'.

**35.155** Dr Keel did not have a recollection of seeing the fax at the time but she considered that colleagues would have made her aware of it. She thought that she would have been surprised by the terms of the fax 'standing the discussions at the meeting' and her understanding of what had been agreed.<sup>230</sup>

---

<sup>226</sup> Ibid pages 137–139

<sup>228</sup> *SNBTS Policy Position on HCV, Briefing Notes for Staff*, 19 May 1994 [SNB.008.4778] (emphasis in original)

<sup>229</sup> Faxed memo from Mr McIntosh to Mr Panton dated 19 May 1994 [SNB.008.4779]

<sup>230</sup> Dr Keel – Day 86, page 140

**35.156** Professor Cash also considered that this fax was premature on the basis that it had been agreed that the SNBTS would wait to be sure that the Scottish Office would go along with it.<sup>231</sup> As it turned out, the Scottish Office was unhappy about this and there was a meeting on 24 May 1994. In a fax from Mairi Thornton to the SNBTS Management Board dated 25 May, she wrote:

David ... asked me to let you know that he, John Cash, Brian McClelland, Jack Gillon and I attended a meeting at SOHHD yesterday where the SNBTS proposal for hepatitis C look-back got a sympathetic hearing.

SOHHD are to consult with the Department of Health in London before a final decision is reached, while the SNBTS is to investigate the operational aspects of introducing a look-back policy.<sup>232</sup>

**35.157** Professor Cash's best recollection of the 24 May meeting was that the Scottish Office officials had made it clear that the SNBTS should not go ahead until given the final instruction to do so.<sup>233</sup> Dr Keel did not remember the meeting on 24 May.<sup>234</sup>

**35.158** This was followed by a faxed letter from David McIntosh dated 30 May 1994 and addressed to SNBTS Regional Directors in which he said:

Following our meeting in the Scottish Office on 24th May this is to confirm that official moves are now afoot to follow up the recent MSC discussions with active consideration of the steps necessary to put an appropriate look back programme into effect.

No final decision has yet been taken ....<sup>235</sup>

**35.159** Mr Tucker was asked to comment on the minutes of the ACVSB/MSBT of 29 September 1994 where he was noted to have said that 'approaches to institute HCV look-back in Scotland had been resisted, and it was important that a UK wide approach was adopted'.<sup>236</sup> He thought it was an inaccurate report of what he had said. Mr Tucker drew attention to an internal note dated 5 October 1994 he had produced of the ACVSB/MSBT meeting where he noted he had told the meeting 'we [the SHHD] had reservations about a look-back unless it was on a UK basis and there were real benefits for patients in treatment'.<sup>237</sup> He added it would not be accurate to say that the SHHD was 'resisting' attempts to introduce HCV look-back.<sup>238</sup> Mr McIntosh considered that, in hindsight, the introduction of look-back in Scotland, as a whole, was delayed due to pressure from England and the natural tendency of Scottish civil servants to acquiesce to pressure from England.<sup>239</sup> He was of the view, shared by Dr Gillon, Dr Keel and Professor Cash, that introducing look-back into England, Wales and Northern Ireland would be a more difficult exercise.

## Towards a decision

**35.160** Over the next few months the DoH appears to have sought advice from the ACTTD/I before making its recommendation. Professor Cash commented on the delay this created, saying 'we were just slightly scuppered there just for a short period of time'.<sup>240</sup> By letter dated 21 June 1994 to the SNBTS Directors, and copied to Dr Keel, Professor Cash advised that the ACTTD/I was to convene an extraordinary meeting to consider look-back and that it was important for the SNBTS to consult with senior hepatologists on look-back.<sup>241</sup> Professor Cash explained that Dr Gillon had come from a hepatology department and that would have made look-back easier for him in comparison, for example, to Dr Mitchell.<sup>242</sup> A meeting was held within the SHHD on 21 September 1994 to discuss SNBTS issues.<sup>243</sup> Dr Keel was present at the meeting along with Mr Tucker, Mr Panton and Mr Wildridge. The minutes record that she had attended a meeting of hepatologists and their view was that look-back was necessary as part of a general 'duty of care'. Dr Keel said that there was general agreement at this stage that look-back should go ahead. She could not remember if any discussions had taken place with DoH colleagues about look-back by this stage although the evidence that the SNBTS had demonstrated that look-back was feasible would have been distributed.<sup>244</sup>

**35.161** Dr Keel stated that it would be wrong to get the impression that look-back was starting to become less urgent. She explained that there was a desire that look-back should proceed on a UK basis. Scotland was slightly ahead of the game and there needed to be a lot of planning and advanced warning to the blood transfusion services in other parts of the UK before they could undertake look-back. She did not consider that the situation south of the border was holding up look-back being implemented in Scotland.<sup>245</sup>

**35.162** The ACVSB/MSBT met on 10 February 1994. The minutes of that meeting have not been recovered. But it is clear that look-back was referred to an advisory committee, the Standing Advisory Committee on Transfusion-Transmitted Infection to the MSBT (SACTTI). The SACTTI reported to the ACVSB/MSBT on 29 September 1994 when Dr Robinson presented their paper.<sup>246</sup> Members of the SACTTI included Professor Cash and Dr Gillon. The recommendation was that there was a serious case for considering a look-back policy for HCV. Dr Gillon's work was not relied on in the report which dealt with the position of the National Blood Service and noted that the facilities were available to undertake tracing, counselling and referral, with a potential case load of 3000 (the number estimated by Dr Gillon at an earlier stage). The outcome on 29 September was a further postponement of any decision, with members asked to submit written comments to be considered at the next meeting.<sup>247</sup>

**35.163** A further Issues Meeting took place on 14 October 1994 at St Andrew's House.<sup>248</sup> Those present were Mr Donald from the CSA, Mr McIntosh, Dr Perry and Mr Tucker, Mr Panton, Mr Wildridge and Dr Keel from the SHHD. It was noted that the ACVSB/MSBT were examining proposals for look-back and would return to the matter in December. It was

reported that the effectiveness of Interferon therapy for HCV infection had been questioned at the meeting of the ACVSB/MSBT on 29 September 1994. Press interest was noted to be 'another potential problem'. Dr Keel and Dr Perry were noted as awaiting the decision but pointed out that 'MSBT had no real locus in this since it was not a matter of blood safety'.<sup>249</sup> Dr Keel thought the comment about the MSBT (ACVSB/MSBT) not having any real locus was a 'nitpicking point' and 'not terribly material to any of the discussions that were going on'. She did not feel that this represented an attempt to 'stall' look-back and did not consider that this represented a change of view within the SHHD, but acknowledged that it would have been undesirable from a Scottish perspective if the ACVSB/MSBT had stepped in and declined to implement the policy from its position as a UK-wide advisory committee.<sup>250</sup> In his evidence, Mr McIntosh said that there had been no need to take the decision back to a scientific committee at that stage. By then it was about practical matters such as logistics and computers, rather than the sorts of matters in which the committee specialised.<sup>251</sup>

**35.164** The MSC met on 10 November 1994.<sup>252</sup> At that meeting, Professor Cash provided an update and introduced discussion on HCV look-back under reference to a report of the recommendations of the SACTTI. The report referred to an ad hoc assembly of experts held on 5 August 1994, convened specifically to discuss the feasibility of look-back, along with others including Professor Tedder, Dr Gillon, Dr Mortimer, Dr Robinson and Dr Alexander.<sup>253</sup> The meeting noted, amongst other things, that, although not clinically apparent in most cases, HCV infection was not trivial, and might cause serious, progressive liver damage leading to cirrhosis and hepato-cellular carcinoma in the long term. It narrated that treatment offered early after diagnosis was mostly likely to be effective in arresting liver damage, while patients with established fibrosis and portal hypertension would not benefit. Early evidence from pilot studies showed that combination therapy with Interferon and Ribavirin might achieve virus clearance in up to 60% of patients. Interferon Alpha was not yet licensed for use in HCV infection. It was also noted that it was still not known whether therapy would affect the long-term natural history of the infection and prevent relapse after therapy was discontinued. Reference was made to the fact that when HCV screening was introduced in September 1991, look-back was not then introduced due to doubts about the long term effects of Hepatitis C, coupled with a lack of effective therapy. Furthermore, secondary transmission of HCV to sexual partners and offspring was then thought to rarely occur. The experts concluded that:

[T]here is a serious case for considering a look-back policy for HCV. To do otherwise, when a look-back programme for HIV already exists, suggests double standards. The wider implications of such a policy will need further consideration and the SACTTI recommends that the Hepatitis Advisory Group and the MSBT consider the matter further as soon as possible.<sup>254</sup>

**35.165** The ACVSB/MSBT met on 15 December 1994. Dr Keel was present as an observer.<sup>255</sup> A report of the SACTTI recommendations on HCV look-back was presented by Dr Robinson. Discussion at that meeting was extensive. It was reported that since the last meeting of the committee, Interferon had been licensed for use in the treatment of HCV

chronic liver damage.<sup>256</sup> Dr Robinson's sub-committee's view was that 'there was a duty of care towards the patients who were affected, and the implicated donors'.<sup>257</sup> Dr Robinson reported that it was now estimated that 60–80% of recipients who developed transfusion-transmitted HCV infection would become carriers and that 50% would develop chronic hepatitis. Twenty per cent of infected recipients might develop cirrhosis. There could be serious implications for the transfusion population.

**35.166** The minute noted Dr Robinson's comments that:

The overriding view of members who commented to the subcommittee, and the view of the sub committee was that transfusion recipients, some of whom may have been harmed, would benefit from a lookback exercise. Liaison with hepatologists would be needed to ensure a consistent and harmonious approach across the UK, and the legal and ethical implications would need to be carefully considered.<sup>258</sup>

**35.167** Dr Metters, the chairman, commented that the lawyers would look to the committee for a view on how to carry out the duty of care. The process would aim to do what was reasonable and not go beyond that. Dr Perry commented that recognition of the duty of care was right, and that:

[T]he Committee's position needed to be clear on what had changed since 1991 to allow look back now.<sup>259</sup>

**35.168** Dr Robinson commented that it was only more recently that the seriousness of HCV had been recognised.<sup>260</sup> Dr Metters suggested that the benefit of treatment which was becoming available, and counselling, were factors.<sup>261</sup>

**35.169** There were some voices of dissent. It was minuted that:

Professor Zuckerman shared the view expressed by Dr Mortimer that the question of lookback was driven by lawyers. It was important to distinguish between those infected with HCV through NHS treatment and by other means.<sup>262</sup>

**35.170** The practicalities of look-back were discussed. However, the CMO intervened in the debate and commented that it was in the public interest that there should be an urgent decision on the matters of principle and that the detail, though important, was less urgent. A comment from Dr Keel was noted:

Dr Keel said that the view in Scotland was that the Secretary of State was vulnerable as look back was feasible since donors could be identified and traced, and advice from Scottish Office lawyers was that look back should start immediately. The Chairman stressed the need for maintaining uniformity in the UK, but said that it was for the Secretaries of State, not the Committee to decide on whether Scotland should go ahead early.<sup>263</sup>

---

<sup>256</sup> Licensing was an important development, expressing the official view of the Committee on Medicines that the product passed all regulatory tests for general use. However, as the paper by Makris et al shows, there had been extensive use of the product before licensing.

<sup>261</sup> Minutes of ACVSB/MSBT meeting held on 15 December 1994 [SNB.008.4820] at 4825

<sup>262</sup> Ibid [SNB.008.4820] at 4825

<sup>263</sup> Ibid [SNB.008.4820] at 4826

**35.171** Dr Keel explained that liability for failing to implement look-back was considered a 'material issue' at the time. Once the SHHD had received legal advice, it had to be taken seriously. She did not remember the issue of liability having dominated discussions until that point but it had now become the main determining factor in the decision to proceed with look-back.<sup>264</sup> It was noted at the meeting that four writs had already been issued against the NBA and that the legal advice received was that the duty of care existed in this case.<sup>265</sup>

**35.172** Paragraph 7.12 of the minutes records the material decision reached at the meeting:

Following the discussion the Committee agreed its advice to Ministers as:

- i. in the Committee's view there is a duty of care towards those infected with HCV as a result of NHS treatment. It follows that procedures should be put in place to identify the patients at risk;
- ii. whatever is done should be done equally and uniformly throughout the UK;
- iii. guidance should be drawn up as soon as possible.<sup>266</sup>

**35.173** At paragraph 7.13 it was noted that the Committee agreed that these conclusions would be passed on to the Secretaries of State of all four health departments.<sup>267</sup>

**35.174** When Dr Keel left the meeting her impression was that the UK Health Departments would advise their Ministers separately that look-back should be undertaken across the UK, that the detail was being worked out by various groups and that this would be based on the results from the south east Scotland 'pilot' study. Her impression was that look-back was now going to be put in place 'pretty quickly', as soon as the blood transfusion services could get the guidance developed and put in place in different parts of the UK.<sup>268</sup>

**35.175** Dr Keel stated that, while the minutes might give an impression of activity, other impressions might be drawn, reading between the lines, which suggested that perhaps things were not going to move as quickly as the SHHD might have desired. She explained that, given Scotland's different position and in view of the legal advice that they had received, there was more pressure on Scotland to move forward than might have been felt in other parts of the UK. In addition, Scotland had some practical experience of running look-back.<sup>269</sup>

**35.176** Professor Cash expressed views on this meeting. He was not present and Dr Metters had reminded members of their duty of confidentiality relating to advice given to Ministers. His interpretation of the course of events at this meeting was that it had been decided that there was no option but to proceed and that 'ministers should be advised to press the button and commence some form of look-back'. Of the many reasons for this, as he saw matters, one was the question of legal liability. He thought that there had been no mention of treatment, for example, though that would have been 'incorporated into the whole concept of legal liability'.<sup>270</sup> It is not appropriate to comment on the stage at

which legal liability might have been triggered by developing forms of treatment. Professor Cash's comment reflects his views that threat of legal liability had been a consideration at least since 1991.

**35.177** Dr Keel thought that she would have come back from the ACVSB/MSBT meeting and briefed departmental colleagues between 15 and 22 December 1994. She would have prepared a note of the meeting, as was her usual habit, and would have noted that she had suggested that Scottish Ministers were vulnerable because of the legal advice that had been received. She met with colleagues to discuss getting on with look-back from a Scottish point of view. She thought that, by this stage, there was a collective view that the SHHD needed to inject a degree of urgency into the matter.<sup>271</sup>

### **The decision in Scotland**

**35.178** Matters came to a head on 22 December 1994 when Lord Fraser of Carmyllie, Minister of State at the Scottish Office covering home and health affairs, wrote to Mr Tom Sackville, the Parliamentary Under Secretary of State at the DoH, intimating that, in the light of the medical and legal advice he had received, he had little choice but to carry forward general look-back which the SNBTS was prepared to implement.<sup>272</sup> Mr Tucker, administrative Head of Division at the SHHD, explained that, as it was his responsibility to formulate and coordinate policy advice to Ministers based on the views of professional experts, he would have put forward a minute to Lord Fraser setting out the advice received and seeking his decision on instituting look-back in Scotland.<sup>273</sup>

**35.179** In 1995 a look-back exercise was commenced throughout the UK to trace patients who had received blood products from donors who were found to have tested positive for HCV.

### **Look-back in place**

**35.180** When look-back began, it identified blood donors who had tested positive for HCV in the years since testing was introduced, covering the period 1991–95. The donor would have tested positive with whichever generation of test was then available and their donation would not have been transfused or used in the preparation of blood products. Previous donations by infected donors, before testing had been introduced, would have been the focus of look-back.<sup>274</sup>

**35.181** The next stage of look-back was an attempt to contact all possible recipients of the infected donor's blood, or blood products, manufactured from that blood at any stage in the preceding years. In some cases that represented a large number of recipients over many years. This was done by contacting the hospital where the transfusion had taken place. Many hospital records were inadequate to match donor and recipient: in the early to mid-1990s records tended not to be retained long-term, with many records having been destroyed in the normal course of records management at the time, and there was no effective, centralised computer system matching donors and recipients. Tracking down the recipient(s) was difficult as they might have moved and there might not have been a clear record of the relevant GP to contact for follow-up.<sup>275</sup>

---

<sup>271</sup> Dr Keel – Day 86, page 153

<sup>272</sup> Lord Fraser's letter to Mr Tom Sackville MP dated 22 December 1994 [SNB.008.4848]

<sup>273</sup> Mr Tucker's statement [PEN.018.0406] at 0406–07

<sup>274</sup> Dr Alexander – Day 85, pages 130–131

<sup>275</sup> Dr Alexander's statement on HCV testing [PEN.018.1360] at 1362–63

**35.182** Where a recipient was identified, a letter was sent by the transfusion service to their GP. The GP may not have had much, if any, experience with HCV and the letters to GPs were carefully drafted to encourage referral and often provided a local contact for further information.<sup>276</sup> It was considered that the GP would be best placed to determine whether any follow-up of the likely infection with HCV should be undertaken or not. (Pursuing the issue of HCV infection might not be helpful for an elderly or infirm patient, or one with a life-shortening disease, for example.)<sup>277</sup> It was then up to the GP to make a referral to a hepatologist or a gastroenterologist with an interest in hepatology.

**35.183** Dr Alexander concluded his statement on HCV look-back by attempting to assess the overall effectiveness of the exercise:

In terms of understanding the disease the exercise has been successful. As a strategy to find all the patients with transfusion related HCV infection retrospectively it has been much less successful. For those individuals found to be positive it has had real benefit. It has allowed those individuals to be processed appropriately and in many circumstances treated effectively. It allowed a large number of them to be compensated financially for developing disease as a consequence of the transfusion.<sup>278</sup>

**35.184** However, professional estimates suggest that only a tiny minority of those who were exposed to HCV have been identified by way of the look-back programme. Research published in 2002 estimated that only five per cent of the total number of HCV infections over the 11-year period to September 1991 have been identified, which represented a higher proportion (13%) of those who were alive in 1995 who had received infected blood.<sup>279</sup> Dr Alexander thought this was a fair assessment of the statistics available on the look-back exercise. Only a small percentage of overall HCV infections were picked up because many of the infected donors stopped coming back, perhaps discouraged by efforts to have high-risk donors remove themselves from blood panels. As he put it, 'if the whole programme is based on a donor coming back and being found to be positive and they don't come back, you are stuck'.<sup>280</sup>

**35.185** In addition, as Professor Cash noted (and as Dr Gillon's exercise had demonstrated several years previously), the numbers of individuals who might have been identified as carrying HCV were diminishing over the period between the introduction of screening and the introduction of look-back. Professor Cash explained that the principal reason for the attrition in terms of finding live patients to treat was death from the 'original pathology ... that had taken them to surgery'.<sup>281</sup>

**35.186** Dr Alexander was asked whether, with the benefit of hindsight, the look-back could have been done differently. He said:

In retrospect and with hindsight one could argue that it would have been more effective to screen all plasma samples that were available from donors (a backlog of three years for the English and longer for the Scottish). However

---

<sup>276</sup> An example of a letter of this type is to be found at [LAI.001.0105]. This was sent to Mr Laing's GP as part of the national look-back programme.

<sup>277</sup> Dr Alexander's statement on HCV testing [PEN.018.1360] at 1363

<sup>278</sup> Ibid [PEN.018.1360] at 1364

<sup>279</sup> Ibid

<sup>280</sup> Dr Alexander – Day 85, page 136

<sup>281</sup> Professor Cash – Day 85, pages 109–110

testing this large number of samples could have crippled the transfusion service from doing its normal every day job.<sup>282</sup>

The English backlog of samples from donors that could have been tested totalled more than six million in 1995. The logistics of testing retrospectively that number of stored donor samples for HCV in England alone, while continuing to run a blood transfusion service, were enormous and would have been very expensive.<sup>283</sup>

**35.187** In oral evidence he added this would have been ‘an enormously difficult exercise’ which would only have been possible with an ‘enormous amount of funding’.<sup>284</sup>

**35.188** Both the practical effectiveness (practicability) and the cost-effectiveness (value for patients) of HCV look-back had been challenged before Dr Gillon’s working group made their recommendation.<sup>285</sup> Later studies, including Dr Gillon’s, reported a low level of recipients of infected blood or blood components, who were alive, testable and HCV-positive.<sup>286</sup> However, as Dr Gillon observed, the measurement of the cost-effectiveness of a look-back programme required monitoring of a wide range of factors relating to mortality, morbidity and prolongation of life that have only recently begun to be fully understood. One outcome of the HCV look-back exercise, the National HCV Register, has followed up as many of the patients identified in look-back as possible, providing a uniquely valuable cohort which was starting to give long-term outcomes in very precise terms.<sup>287</sup>

**35.189** Dr Gillon commented that Danish researchers reporting on the outcome of an HCV look-back programme in their country could demonstrate no significant benefit in terms of mortality compared to non-infected transfused patients; they had, however, shown very considerable morbidity in the HCV-infected patients, which was amenable to treatment in a great many cases. The Danish researchers noted a cure rate of close to 50% for patients who were treated with Interferon, an early indication of emerging evidence of benefit for that group of patients.<sup>288</sup> Dr Gillon commented that the benefit people living with HCV obtained from treatment was an indication in favour of targeted look-back.<sup>289</sup> That appears clearly to be correct: finding NHS patients who had been infected by transfusion of blood and blood components may not have achieved a high success rate, but for every patient identified and treated successfully the potential benefit was considerable.

**35.190** Although a clearly measurable benefit has not yet been demonstrated in terms of overall mortality, Dr Gillon anticipated that a cost-effectiveness analysis may be carried out in the future. The Health Protection Agency Study would be extended long enough to show one way or the other whether patients did benefit.<sup>290</sup>

**35.191** Dr Gillon considered that further, incidental, benefits had been achieved by look-back. He considered that the UK transfusion services had regained a measure of trust with

<sup>282</sup> Dr Alexander’s statement on HCV testing [PEN.018.1360] at 1364

<sup>285</sup> Busch, ‘Let’s look at human immunodeficiency virus look-back before leaping into hepatitis C virus look-back’, *Transfusion*, 1991; 31:655–661 [PEN.017.2307]

<sup>286</sup> For example, Just et al, ‘Long-term follow-up among Danish transfusion recipients identified in the national hepatitis C lookback’, *Transfusion*, 2012; 52(3):582–8 [PEN.018.0507]; Ayob et al, 1994 [LIT.001.3802]

<sup>287</sup> Dr Gillon – Day 86, pages 78–80

<sup>288</sup> Just et al, 2012 [PEN.018.0507]. It has to be noted that the nearly 50% cure rate was not achieved with Interferon alone. It reflected the use of more modern Interferon plus Ribavirin combination treatment after about 1998.

<sup>289</sup> Dr Gillon – Day 86, pages 81–83

<sup>290</sup> Ibid pages 79 and 84

the public. There had been various media campaigns when the decision was taken to start look-back and comments adverse to the reputation of the transfusion service had emerged. It was felt to be important to calm down the atmosphere and show that the SNBTS had done something about the problem. Lessons had been learnt from look-back, as reflected in the response to variant CJD (Creutzfeldt-Jakob disease) and other problems.<sup>291</sup> Dr Gillon accepted that it would have been better to have been preventative rather than reactive, but considered that things had progressed rapidly when it was eventually accepted that look-back had to be implemented.<sup>292</sup>

### The ethical considerations

**35.192** The Inquiry had an interest in investigating why four years elapsed between the commencement of universal HCV screening for blood donors on 1 September 1991 and the introduction of the UK general look-back in mid-1995, and whether any ethical or other issues arose relative to the course of events.

**35.193** Lord Fraser's letter indicated that part of the reason for lack of follow-up action on identifying infected donors had been:

[A] concern that it would be impossible to identify all recipients of infected blood and even if it were possible there was a lack of accepted treatment which would be beneficial. It was accepted that if no effective treatment was available, informing those patients who were unaware of their situation could not be justified, since this would cause further distress and anxiety without any benefit.<sup>293</sup>

**35.194** Against the background of changing perceptions of the doctor/patient relationship discussed in preceding chapters and, in particular, in Chapter 32, *An Investigation into the Systems in Place for Informing Patients about the Risks – Ethical Context*, the advice given to, and repeated by, Lord Fraser might be seen as an example of the paternalism of the 1970s. This attitude continued long after significant changes in opinion initiated by British Medical Association (BMA) and General Medical Council (GMC) publications in the late 1980s. Professor Nathanson, Director of Professional Activities at the BMA, responsible for overseeing the association's work on medical ethics and teacher at the universities of Cambridge and Durham, commented that the passage from Lord Fraser's letter was a common reason given at the time for not going ahead with a look-back programme. She said:

It has ... commonly been argued that where that information would bring them only uncertainty, where there was no treatment available, that you couldn't justify causing distress and anxiety. So that last sentence is a sentence that I would recognise as being one that has been commonly cited.<sup>294</sup>

**35.195** However, from a contemporary ethical perspective, Professor Nathanson asserted that individuals have a right to be told information about their health, about their own body and about infections without any qualification, including of the type set out by Lord Fraser. Further, patients aware of their diagnosis had other potential benefits. They could take steps to take care of themselves, even where no treatment was available,

---

<sup>291</sup> Ibid pages 85–86

<sup>292</sup> Ibid page 85

<sup>293</sup> Lord Fraser's letter to Mr Tom Sackville MP dated 22 December 1994 [SNB.008.4848] at 4848

<sup>294</sup> Professor Nathanson – Day 84, page 53

such as by reducing or abstaining altogether from drinking alcohol. They could also be closely monitored and be offered the opportunity of drug treatment as soon as it became available. If they were monitored, their clinicians did not lose contact and the patient would hopefully be contactable when a treatment became available. Otherwise, when drug treatment became available, the patient might be difficult to locate and valuable time would be lost.<sup>295</sup>

**35.196** In addition, if the medical profession does not give people information they hold about them, trust can be lost. If a patient might require unpleasant and closely monitored treatment in the future, requiring a lot of cooperation between doctor and patient, then the fact that information had previously been withheld could undermine that trust.<sup>296</sup>

**35.197** Less generously, it has to be noted that patients who were not informed of their exposure to virus infection were not in a position to take advice, medical or legal, on the implications of having been infected in the course of medical treatment. Lord Fraser had legal as well as medical advice in forming his views. It is appropriate to discuss the issue more fully.

**35.198** It is not for this Inquiry to provide an answer, as a matter of generality, to the question when legal liability might have crystallised, having regard to the availability on general prescription of drug therapy for liver disease resulting from HCV infection. That may depend on circumstances, including the availability of a drug on a named patient basis prior to licensing, and whether the patient was, or could have been, given a choice whether to accept therapy. Professor Nathanson's evidence (paragraph 35.195) has considerable weight. Instant availability of effective therapy, and the risk of legal liability, are not the only issues relevant to look-back policy. Pharmaceutical research may result in new products, or the refinement of existing products, which are beneficial to those infected with HCV. Look-back provides an opportunity for those infected through infected donations to become aware of their condition and to benefit from such new, or refined, products.

**35.199** Professor Cash stated that he strongly supported all of the reasons that Lord Fraser gave in the letter. The SEBTS study had shown that look-back was 'feasible and practicable'.<sup>297</sup> Treatment for HCV was available for general prescription following licensing. And the letter acknowledged the central argument about potential liability which resulted, in his view, from these conclusions. He was referred to the section of the letter which stated that the matter of a look-back policy for HCV was considered by the ACVSB/MSBT, which had advised that procedures should be put in place to identify those at risk but that 'whatever is done should be done equally and uniformly throughout the UK'.<sup>298</sup> His attention was also drawn to the passage which narrated that the advice that Lord Fraser had received from his medical and legal staff had led him to conclude that 'I consider it is no longer a matter of policy but of legal liability, and that look-back should take place as soon as possible in Scotland'.<sup>299</sup> Professor Cash acknowledged that Lord Fraser was conscious that the advisory committee was not advocating immediate implementation of look-back but that, notwithstanding that, Lord Fraser was planning to go ahead with look-back in Scotland. Professor Cash again supported that approach. He accepted, by reference to this letter, that the position in 1991 when screening was introduced was that

---

<sup>295</sup> Ibid pages 53–54

<sup>297</sup> Lord Fraser's letter to Mr Tom Sackville MP dated 22 December 1994 [SNB.008.4848]

<sup>298</sup> Ibid [SNB.008.4848]

<sup>299</sup> Ibid

it was the Scottish Office which had responsibility for deciding whether look-back should be implemented in Scotland. He explained that that was because extra resources were going to be required, and in his view at the time it would have required a CMO letter 'to get things going'. In these respects, the position was the same in 1991 as it was at the time of Lord Fraser's letter.<sup>300</sup>

**35.200** Professor Cash was referred to the section of the letter which suggested that the SNBTS could be considered negligent if it did not proceed with look-back. Dr Mitchell had written to him on 14 May 1990 commenting that Glasgow and West of Scotland RTC at that time had no look-back policy, and that the Service could be considered to be negligent in not advising about potential future use of donor blood.<sup>301</sup> He was asked if this was, perhaps, sounding a 'distant alarm bell'. Professor Cash said that he did not consider that Dr Mitchell was the originator of the alarm bell; he considered that everybody was beginning to think about the implications. He recalled there had been concern in September 1988 at a meeting of a group of people, who included Scottish Office lawyers, about the potential for litigation that would arise from HIV transmission by blood and blood products. Professor Cash considered that this was a landmark meeting at which people 'eventually began to talk about who had the duty of care and legal responsibility'. He explained that they had all been 'fretting' about look-back.<sup>302</sup>

**35.201** The stage at which legal liability crystallised with the general availability of an effective treatment for liver disease may well have been the last point at which to introduce look-back. But it cannot be concluded that that was necessarily the first stage of importance.

## Discussion

### *Policy on look-back*

**35.202** From 1991, there was a clear UK transfusion service policy on HCV look-back, following the advice of the ACVSB/MSBT at its meeting on 25 February of that year. After the introduction of anti-HCV screening, look-back would 'not be undertaken as a service leaving the option for those carrying out research. However all cases of post-transfusion hepatitis should continue to be investigated'.<sup>303</sup>

**35.203** That was a qualification of the agreement between Professor Cash and Dr Gunson recorded in Professor Cash's letter to the Scottish Transfusion Directors dated 9 July 1990, in which it was said that investigation of donors implicated in cases of reported post-transfusion hepatitis would continue in the period before anti-HCV was introduced, but that, from that date, it would not be appropriate to introduce a systematic look-back programme on previous recipients of donations. Witnesses were agreed that the letter referred to reverse look-back and, if so interpreted, it implied a more comprehensive ban on look-back than emerged in February 1991.

**35.204** It would be inappropriate, however, to apply too rigidly the definitions of look-back introduced in paragraphs 35.3 and 35.4 of this chapter. The terms 'targeted look-back' and 'reverse look-back' associated with the definitions do not appear to have been in common use in the UK transfusion service, so far as disclosed by the contemporaneous correspondence and records of committee proceedings recovered by the Inquiry. From a

review of the whole evidence it is generally possible, with the benefit of expert help such as provided by Dr Gillon, or from the context in some cases, to interpret the documentary evidence and form a view whether individual documents referred to 'targeted look-back' or 'reverse look-back' as now defined. Examples have been noted in the narrative of the evidence.

**35.205** However, to adopt the terminology now in use, the advice of the ACVSB/MSBT in February 1991 can be expressed in this way. Following the introduction of anti-HCV screening reverse look-back should continue as it had in the past, providing for the investigation of the source of transmitted infection where a transfusion patient had acquired HCV infection. Otherwise there should be no systematic look-back programme. On that view, systematic targeted look-back would be inconsistent with UK, including Scottish, Health Department policy from February 1991.

**35.206** When Professor Cash read the guidelines prepared by Dr Gillon's group in September 1990 it would have been apparent to him that targeted look-back was proposed, and it would equally have been apparent that that was contrary to the agreement on policy he had reached with Dr Gunson and reported in July 1990. His response was that the SNBTS required to think about the issue carefully. He circulated the report to the Regional Transfusion Directors and to Mr McIntosh in anticipation of the MSC meeting of 6 November 1990. There was no representative of the SHHD at that meeting, though the BTS was represented by the Regional Transfusion Director for Leeds who spoke for Dr Gunson.<sup>304</sup> In the event, the meeting did not make a decision on any matter or principle, but commissioned Dr Gillon to re-draft his proposals as Standard Operational Procedure guidelines.

**35.207** The issue of principle was referred in the first instance to Dr Metters, and the SHHD and professional members of the ACVSB/MSBT were copied into the correspondence.<sup>305</sup> Professor Cash's letter did not disclose Dr Gillon's recommendations. It simply invited Dr Metters to refer to the ACVSB/MSBT the SNBTS Directors' request that a policy of look-back (without further specification) be considered. Consequently, there was nothing to alert Dr McIntyre, of the SHHD, for example, to the fact that any particular departure from UK policy was in contemplation. As indicated in paragraphs 35.62–35.65, the precise sequence of events at the end of 1990 and in early 1991 remains obscure. By the meeting of the MSC on 19 February 1991 'national events' had come into play and led to agreement that no look-back should be introduced at that stage. The advice of the ACVSB/MSBT was more qualified but excluded a systematic look-back programme. That would have excluded the exercise proposed by Dr Gillon and his colleagues as contrary to UK and Scottish departmental policy on look-back. Having regard to later comments about the role of the ACVSB/MSBT in relation to look-back, it is significant that even at this early stage in events the committee was engaged in discussion as, effectively, the source of authoritative guidance on issues around look-back.

**35.208** Consistently with the policy position adopted, Professor Cash wrote to Dr Gillon on 12 March 1991 advising that the guidelines should be amended to exclude the references to targeted look-back. The outcome was that Professor Cash had 'tested the water' with Dr Metters and through him the ACVSB/MSBT without disclosing Dr Gillon's proposals and without compromising the agreement he had reached with Dr Gunson.

<sup>304</sup> Minutes of the first meeting of the SNBTS Medical and Scientific Committee on 6 November 1990 [SNB.009.5513]

<sup>305</sup> Referred to at paragraph 35.60 above

**35.209** As narrated above, when confronted with Professor Cash's letter dated 12 March 1991, Dr Gillon, with the support of Dr McClelland, resolved to go ahead with targeted look-back in the SEBTS region. This can be seen, in hindsight, as a highly principled act, in defiance of national policy, and it should be said immediately that in the view of this Inquiry Dr Gillon's actions were highly commendable.

**35.210** Dr Gillon considered that the SEBTS ought, and should be able, to carry out a look-back exercise from September 1991, the date upon which donor screening for HCV was to commence. Suitable second-generation tests were becoming available and a confirmatory PCR test for HCV was in the later stages of development. From Dr Gillon's point of view, the initiatives taken in south east Scotland reflected the correct ethical response to donors following the introduction of HCV testing. It is important to note the basis for that view. His experience of the HIV era was a material consideration. In relation to HCV, the dilemma arose for him as a doctor as soon as a donation was confirmed as HCV-positive: by the following day he would have the donor's records on his desk with information showing whether there were previous donations and, therefore, whether the donor might have transmitted HCV infection. From that point he had means of obtaining access to information about previous recipients.<sup>306</sup>

**35.211** He accepted that there were important differences between HCV and HIV. Consequently, one could not necessarily compare the decision immediately to institute targeted look-back for HIV with the long process before a similar procedure was instituted for HCV. The health implications of positive diagnoses for the two diseases were very different. The prevention of the secondary spread of HIV, despite the absence of treatment, could have been a reason for proceeding with HIV look-back. With HCV, for a long time there was no information on its sexual transmission and once such information became available it demonstrated much lower levels of sexual transmission.<sup>307</sup>

**35.212** He explained, however, that to his mind 'previous donations' translated directly into 'previous recipients' and he felt that he could not in all conscience ignore that information. He saw it as part of his duty of care to the recipients of potentially infected blood to ensure that their clinicians had that information, irrespective of whether there was any treatment available at that time.<sup>308</sup> Dr Gillon's views on this matter accord with the ethical duties that Professor Nathanson considered incumbent on a doctor in the doctor/patient context in the early 1990s.

**35.213** Dr Gillon's first report to Professor Cash was dated 20 September 1990, and the ethical dilemma was clearly expressed in it.<sup>309</sup> There were logistical difficulties, sufficient at the time to persuade the AABB that look-back should not be recommended. (However, as highlighted above, it was perceived in the USA that surrogate testing had limited the risk of infected individuals continuing to donate blood.) As noted in paragraph 35.48 above, Dr Gillon's group considered the AABB position to be untenable, given the desirability of informing recipients so that they could protect others, and also receive treatment with Interferon if the benefits of this form of therapy were confirmed.

<sup>309</sup> Letter from Dr Gillon to Professor Cash dated 20 September 1990 [SNB.004.5074]

### *Dr Gillon's look-back project*

**35.214** The screen samples used in the SEBTS exercise were obtained between 1 September 1991 and 29 February 1992. The Ayob paper reporting on the exercise in the SEBTS was published in 1994. It had been submitted for publication in November 1993 and accepted for publication on 21 July 1994. It disclosed the time taken for the exercise in terms of medical and secretarial hours. But it did not disclose the time taken for the analysis of the study for the paper or for the preparation of the report itself. However, a brief account of the project had been included in Dr Gillon's paper for the College of Physicians symposium in October 1993 (albeit mis-described). Professor Cash alerted Transfusion Directors to the need to review the policy on look-back in his letter dated 15 October 1993, with particular reference to the views of Dr Dusheiko. The MSC debated the issue at its meeting in November 1993.

**35.215** By autumn 1993 therefore, it was highly likely that the SEBTS initiative would become known to a wider constituency. Subsequently, it must also have become clear to those concerned with UK and Scottish Health Department policy, as they came to appreciate what had been done, that the report related to an activity that was in fairly flagrant breach of national policy guidelines. The Ayob paper stated that UK policy, in common with American policy, was against look-back. However, before looking at the evidence relating to the official response, it is necessary to consider what was known about the SEBTS initiative between 1991 and mid 1994, and by whom.

**35.216** Dr Gillon said that he thought that he informed Professor Cash of the look-back exercise at some point between March 1991 and September 1991. That evidence is accepted. Professor Cash's own recollection of events was imprecise and, in any event, he stated that he was prepared to defer to Dr Gillon on the matter. When the exercise began, it seems likely that anyone alert to what was happening in the SEBTS would have understood that some initiative was in hand. Of the 42,697 donors screened routinely, 20 were identified as HCV-positive. Fifteen had given previous donations from which 83 components had been prepared. All of these were investigated. It was a major exercise involving accessing a large number of records and involving a significant investment of time. It was not carried out in secret, and given its scale it could hardly have been clandestine, but it seems highly likely that there was no attempt to publicise the exercise while it was in progress. Dr Gillon may have informed Professor Cash of the exercise for any number of possible reasons, one of which may have been that it was a prudent precaution to take in order to ensure that there would be no interference with it once it had begun.

**35.217** On the other hand, it appears likely that other SNBTS Transfusion Directors were not informed of it until at or after the October 1993 symposium, depending on whether or not they heard Dr Gillon's address. That is not surprising. As discussed throughout this report, the several regions of the SNBTS largely operated as separate autonomous organisations, each implementing their own policies which might coincide with or differ from others' on an uncoordinated basis. Professor Cash's letter of 15 October 1993 did not mention Dr Gillon's work in raising the issue of look-back with the Transfusion Directors. As matters transpired at the MSC meeting on 9–10 November 1993, the Directors wanted further information from Dr McClelland, and time to think. Accordingly, it appears likely that they had not been kept informed of the SEBTS initiative before that point. It is likely that it was as a result of that meeting that the Directors became 'generally aware' of Dr Gillon's work, in Professor Cash's words (see paragraph 35.107).

**35.218** Mr McIntosh considered that he had been 'duped'. At some stage he had been informed by Professor Cash that the SEBTS was conducting a 'pilot study' of look-back procedures. Professor Cash said that he had suggested the title and his evidence on this matter is accepted. The title was devised in order to avoid questions about the SEBTS project. It is likely that it was a matter of indifference to Dr Gillon how the project was described so long as he could get on with the work. A 'pilot study' on look-back was less of a challenge to national policy than a systematic targeted look-back investigation of all anti-HCV screen positive returning donors and the recipients of blood or components obtained from their donations. Professor Cash had an interest in representing the exercise as one limited in scope. And, as Dr Gillon's anecdote at paragraph 35.109 makes apparent, Professor Cash appears to have been concerned to make it clear to others that the initiative was not an SNBTS pilot, but strictly an SEBTS matter. In his oral evidence, Professor Cash explained his position: there was a great deal of sensitivity in government circles about look-back, and opposition in some quarters. In the circumstances described, it is reasonable to infer that if action against Dr Gillon's initiative were to be avoided, it was necessary to resort to a degree of subterfuge. And it succeeded. Dr Gillon was able to proceed to complete the project without interference. The CSA, as represented by Mr McIntosh, did not understand the nature of the project, and there was no adverse reaction from any agency.

**35.219** It appears likely that the SHHD had no knowledge of the project until the autumn of 1993 at the earliest. As understood by Dr Keel, the position of the SHHD from the time she joined the service until early 1994 was that Scotland should not be implementing look-back because it was not thought feasible and because there was no evidence-based therapy available for treating infected individuals. Those views were shaped and influenced by statements by the SNBTS Directors, by UK committees, and by the department's understanding of expert opinion 'across the UK and abroad'. Broadly the SHHD reasons for believing that look-back was not appropriate reflected the views of the ACVSB/MSBT.

**35.220** It is apparent from Dr Keel's evidence that the feasibility of a look-back exercise in Scotland, generally, became clear to her on 18 May 1994. Several features of her recorded actions on that day demonstrate that she was unprepared for what Dr Gillon had to say. She was in error in suggesting that the SHHD might not have a locus, given their role in policy matters, but that may have resulted from her inexperience in her post. Her anxiety to return to base and discuss what she had heard with SHHD colleagues was indicative of the fact that she had come to the meeting unprepared by such discussion in advance of the meeting.

**35.221** It is slightly less easy to understand why Dr Keel should have been in that position. Dr Keel was at the October symposium at which look-back was aired, to some extent at least, by Dr Gillon. Even if one discounts Professor Cash's more exuberant observations on the impact of Dr Dusheiko's contribution, Dr Gillon's paper did disclose that look-back had been explored in the SESBT region. However, it may be, as Dr Gillon suggested, that despite his airing of the subject only Dr Dusheiko and 'one or two others' had their interest caught by it. Professor Cash, who had arranged the symposium and, apparently, had a particular interest in look-back at the time, also had no recollection of the subject matter of Dr Gillon's talk. Dr Keel was not copied in on Professor Cash's letter of 15 October 1993 to transfusion colleagues, which indicates that he was not then ready to open up the policy issue directly with SHHD colleagues before he had discussed it at the MSC. However, Dr Keel was present at the MSC discussion.

**35.222** The MSC discussed look-back on 10 November 1993, as anticipated in Professor Cash's letter. The minute of that meeting records that full discussion took place of what was clearly a targeted look-back scheme (see paragraph 35.128). Dr Keel is recorded as having been present for item 4.6 which included the discussion of 'Lookback: HCV' as a new agenda item but Dr Gillon was not present. Consequently no presentation by him, such as Dr Keel witnessed on 18 May 1994, was then made. The record indicates clearly that, while decision was postponed, what had been envisaged was a policy decision on the item. It may be that the consensus to postpone the decision together with the concerns expressed by the directors in relation to the potential difficulties with the practicalities likely to be encountered in Inverness, Aberdeen, Dundee and the west of Scotland reinforced her then extant view that look-back was not feasible for Scotland as a whole or considered an urgent matter. Undoubtedly, the SEBTS was uniquely well-placed within Scotland to carry out a look-back exercise due to its blood banking system, the expert assistance available to it and the IT resources that it commanded. The action log following from the meeting, which provided background to the agenda for the meeting on 18 May 1994,<sup>310</sup> indicated that Professor Cash was to ensure that 'look-back-HCV' received further discussion. The 'Discussion Topics For Future MSC Meetings', attached to the agenda for the 18 May 1994 meeting, included 'HCV confirmed positive donors-look-back'.<sup>311</sup> No name or initials were provided for any 'presenter' and no priority rating had been allotted to the item. The action log, also attached to the agenda of 18 May 1994, suggested that the ACTTD/I were then discussing look-back. The SHHD was not represented on the ACTTD/I. Dr Keel was at the issues meeting on 16 May 1994. At that meeting targeted look-back was discussed. The minute records that Mr McIntosh would send a draft policy statement to the Department for clearance.

**35.223** If Dr Keel had sought the advice of other medical and policy colleagues before the meeting of 18 May, it seems reasonable to speculate that, despite her relative inexperience, she would not have inadvertently misrepresented the SHHD position at it. However, in the absence of any reference to HCV look-back on the agenda, it is not surprising that she did not consider that there was any need to do so. At the meeting on 24 May, arranged after the issues meeting of 16 May 'following further developments after the meeting', it was indicated that the SNBTS proposals for targeted look-back got a sympathetic hearing, but the decision was that the DoH would be consulted before a final decision was reached. Notwithstanding the impact of Dr Gillon's presentation, the SHHD still required to consult with the DoH and it seems likely that that would have been the attitude of SHHD officials whenever confronted with SNBTS proposals for targeted look-back.

**35.224** It is worth noting that in the autumn of 1993, Professor Cash's approach to targeted look-back, in recorded exchanges, appears to have been decidedly low-key. The records of the MSC meetings of November 1993 and May 1994 indicate clearly that, within the SNBTS community, Professor Cash was at pains to ensure that look-back was kept on the agenda. However, there is no indication in any of the correspondence that he was a passionate advocate held in check by more cautious transfusion directors.

**35.225** At the meeting of the ACTTD/I on 18 January 1994, Professor Cash explicitly relied on Dr Dusheiko's advocacy of targeted look-back. He did not then disclose Dr Gillon's completed work, and his proposal for action emphasised the need for research,

<sup>310</sup> List of action points attached to agenda for meeting of SNBTS Medical and Scientific Committee on 18 May 1994 [SNB.009.9172] at 9173

<sup>311</sup> Discussion Topics for Future MSC Meetings [SNB.009.9175]

probably involving a research grant application. Interestingly, it was remitted to Professor Tedder and Dr Barbara to examine protocol options for look-back. Scottish experience and capacity were not mentioned. But a corner had been turned: the committee supported the concept and encouraged grant seeking for the undertaking. It is against this background that the proceedings of the MSC on 18 May 1994 have to be considered, and the wider publication of Dr Gillon's programme has to be understood. It was, at very least, consistent with the thrust of the decision of the ACTTD/I, though not as yet the ACVSB/MSBT.

**35.226** The ACVSB/MSBT met on 10 February 1994. The minutes of that meeting have not been recovered. But it is clear that the matter was referred to the SACTTI. On 29 September 1994, Dr Robinson presented the SACTTI recommendations to the ACVSB/MSBT. Members of the SACTTI included Professor Cash and Dr Gillon. The recommendation was that there was a serious case for considering a look-back policy for HCV. Dr Gillon's work was not relied on in the report which dealt with the position of the NBTS and noted that the facilities were available to undertake tracing, counselling and referral, with a potential case load of 3000 (the number estimated by Dr Gillon for the rest of UK other than Scotland). The outcome on 29 September 1994 was a further postponement of any decision for members to submit written comments. The disposal of the issue of principle took place at the next meeting of the ACVSB/MSBT on 15 December 1994, and is narrated in paragraphs 35.165–35.173. Practical implementation of look-back was in the event accelerated by the actions of Lord Fraser of Carmyllie on 22 December 1994, and took place in 1995.

#### *Earlier implement of targeted look-back in Scotland*

**35.227** Lord Fraser of Carmyllie's letter answers conclusively the question whether Scotland was prevented by wider UK policy considerations from proceeding with targeted look-back from 1 September 1991. The Inquiry was not directed to any change in the law between 1990 and December 1994 that would have had a bearing on the advice Lord Fraser might have had from his legal advisers on the obligation to pursue look-back. There may, however, be questions as to whether the factual, circumstantial, context had changed over that period such as might have affected the enforceability of the general duty of care. Any relevant questions would then have related to the known facts, including those relating to the feasibility of look-back in Scotland. Crucial facts would have included:

- The reliability of available screening tests.
- The traceability of prior donations by a donor testing positive for anti-HCV after confirmation testing.
- The identification of potentially infective prior donations.
- The traceability of recipients of those donations.
- The availability or likely availability of treatment.

**35.228** The logistical difficulties associated with look-back have been rehearsed above: they were real and substantial and, as events were to prove, the relative failure of look-back when it was implemented was in part due to those difficulties. But by 1 September 1991, Scotland was in a particularly favourable position. The use of first-generation screening tests might have caused difficulties in some regions of England and Wales, as would the late and patchy availability of PCR tests, as described by Dr Alexander. However, prior to the introduction of routine screening in September 1991, it was known in Scotland, firstly, that the more sensitive and specific second-generation ELISA tests would be available

for routine screening and, secondly, that the RIBA confirmatory tests would also then be available. Furthermore, Professor Simmonds' PCR test was known to be available from the turn of 1990–91. As Dr Gillon explained, Scotland was one of the very few countries, and might have been the only country, that had PCR testing available as part of their confirmatory algorithm right from the outset, substantially ensuring reliable diagnosis for those found positive. When a donor was confirmed anti-HCV positive after 1 September 1991, they *knew* they were positive and this together with the excellent IT resources, assistance and blood banking system put the south east region of Scotland where Dr Gillon operated, in a particularly favourable, and possibly unique, position to initiate look-back from the very outset of screening as he had advocated. However, that was not the case for the rest of Scotland as became apparent at the MSC meeting at the end of 1993. A number of logistical difficulties, some of which are likely to have been exacerbated by the passage of time, had to be overcome when the UK look-back exercise began in 1995.

**35.229** Whenever precisely the feasibility of a look-back exercise in Scotland as a whole was, or should have been, established, a further matter which requires to be addressed relates to the availability of effective treatment. On his own evidence, Professor Cash, among others, became convinced of the inevitability of a look-back exercise as a result of Dr Dusheiko's address at the HCV symposium in October 1993 at which the use of Interferon was advocated as an effective therapy. Even if, contrary to the views of Professor Nathanson and Dr Gillon, the availability of a remedy could legitimately be considered central to the policy issue, there was strong evidence from that point onwards that Interferon was a possible candidate. However, at the MSC meeting in November 1994 Professor Cash reported on the discussions at the SACTTI, which included those relating to the early results of the Interferon and Ribavirin combination pilot study, the lack of a licence for Interferon and the lack of evidence as to whether the therapy would affect the long term natural history of the condition, including preventing relapse after therapy was discontinued.

**35.230** Further, it is a material consideration that Interferon was not licensed until November 1994. The licensing procedure did not prevent the use of the drug on a named patient basis, and Dr Dusheiko made it clear that there had been extensive use of it. On the other hand, it is highly unlikely that the SHHD or the DoH would, or could, have formulated and implemented a national policy that depended on treatment with the use of a drug that was still in the course of assessment by the Committee on Safety of Medicines as part of the licensing procedure. Apart from any risk to patients, the integrity of the licensing procedure itself would have been challenged if either had done so. Whether a decision on licensing of Interferon could have been accelerated would depend on pure speculation.

**35.231** As matters transpired, the Chief Medical Officer's intervention at the meeting of the ACVSB/MSTB on 15 December 1994, and Lord Fraser's letter to Mr Sackville on 22 December 1994 followed the licensing of Interferon. On all the evidence available to the Inquiry, it is not possible to conclude that an earlier decision on UK-wide or Scottish policy could have been reached.

**35.232** It is unfortunate that matters were so long drawn out. Time was the enemy of effective identification of patients who might benefit from management that took account of their infection. Not only was there a risk of progression beyond the stage at which intervention by therapy was likely to be effective, but patients also were lost

through death or the breakdown of communication links. However, it must also be borne in mind, as Dr Gillon noted in his evidence, that the look-back exercise undertaken in 1995 in the UK was one of the earliest comprehensive look-backs instituted in the world

## Conclusions

**35.233** Targeted look-back could not have begun before the commencement of routine screening. In Chapter 31, *The Introduction of Screening of Donated Blood for Hepatitis C*, it is concluded that a decision to recommend to Scottish Ministers that government policy should include a commitment to routine screening of blood donations for anti-HCV should have been taken by the middle of May 1990, with implementation unlikely much before autumn 1990, having regard to the supplies of test kits available.

**35.234** There were no scientific or medical grounds on which routine screening of blood donations in Scotland required to be started simultaneously with the rest of the UK. Successive delays in the uniform start date were influenced largely by problems relating to introducing screening in England and Wales, which had no parallel in Scotland. Scottish Office Health Ministers and the Secretary of State were not informed that financial and other problems affecting only England and Wales were delaying the start date, and advised that the policy of a uniform start date ought to be reviewed. Action, or inaction, on the part of a number of individuals (as more fully set out in Chapter 31) resulted in the opportunity being lost for a more prompt introduction of screening in Scotland. Consequently, Scottish patients lost, firstly, the benefit that would have accrued to them from the early introduction of screening and, secondly, the reduction in the risk of acquiring HCV by transfusion of unscreened, infected blood. What Scottish Office Health Ministers or the Secretary of State would have done with such information can only be a matter of speculation, but in its absence they were deprived of the opportunity to consider the issue and resolve it as they saw fit. In the event, 1 September 1991 became the earliest date at which look-back could have been commenced.

**35.235** If routine screening had been introduced earlier in Scotland, Dr Gillon would probably have gone ahead with the SEBTS project earlier, and the feasibility of look-back for the SEBTS at least would probably have been established earlier. However, as Dr Gillon noted, the work involved in the introduction of universal screening put the look-back debate on the back seat as the development of confirmatory procedures, time required to deal with false positives and the counselling of genuine positives kept people 'pretty busy'. That consideration would have applied whenever screening was introduced. In any event, none of these matters would have affected the licensing process for Interferon. Though from the introduction of Interferon treatment on a named patient basis in England in 1989 and in Scotland in 1990, therapeutic use was a reality, and there was the prospect of improved products being introduced in the ordinary course of research and development by pharmaceutical companies, the licensing of the product was an unavoidable aspect of the regulatory regime in the UK and applied in Scotland as it did in the rest of the UK.

**35.236** At the ACVSB/MSBT meeting in December 1994, Dr Perry expressed his concern that the committee should make clear what had changed between 1991 and that meeting to justify the decision on 15 December to 'allow look-back now'. The report of Dr Robinson's sub-committee provides part of the answer, so far as the ACVSB/MSBT is concerned.<sup>312</sup> However, the Inquiry does not have sufficient evidence about the situation

---

<sup>312</sup> Paragraphs 35.166–35.167 above

in England and Wales to provide an analysis or critique of the deliberations and decisions of the ACVSB/MSBT in relation to those parts of the UK over this critical period. So far as Scotland is concerned, Dr Keel emphasised that the ACVSB/MSBT was the principal UK Advisory Committee and that it would have been the committee that the SHHD 'would have looked to for a steer on this look-back'.<sup>313</sup> It is clear, however, that the sequence of events leading up to Lord Fraser's initiative did not reflect the outcome of requests from the SHHD for advice from the ACVSB/MSBT. On this occasion, Lord Fraser proceeded on Scottish advice.

**35.237** Lord Fraser's letter simply reflected the independent obligation of the Scottish Office Health Ministers to act in the best interests of Scottish patients, an obligation that existed throughout the relevant period and beyond. The clear expression of the legal obligation was not a new factor: the advice of law officers on that issue would have been the same whenever the question was put to them. As far as medical advice is concerned, Dr Keel was the main medical advisor at this point in time. She provided counsel on the medical and clinical benefits of look-back. Her own view had been formed by meetings that took place in the months preceding Lord Fraser's letter, as well as by SNBTS advice, particularly in relation to the SEBTS study. Latterly, she had also met with experts including hepatologists. In May 1994 she, and thereafter the SHHD, became convinced that look-back should be carried out in Scotland as a whole, and the SNBTS and the SHHD worked towards that end.

**35.238** The potential seriousness of NANB Hepatitis, and therefore of HCV infection, had been established in the second half of the 1980s. The suggestion at the ACVSB/MSBT meeting on 15 December 1994, reported at paragraph 35.168 above, that it was 'recently' recognised that HCV was potentially a serious condition is inconsistent with the evidence obtained by the Inquiry. The research of Dr Hay's Sheffield group using biopsy showing a high prevalence of serious morbidity in patients with NANB Hepatitis infection, was published in 1985. The Sheffield findings did not become generally accepted opinion immediately. However, the analysis of the clinical manifestations of infection in the eighth edition of Sherlock's *Diseases of the Liver and Biliary System*, 1989, and indeed Professor Zuckerman's 1988 paper on 'Unresolved issues in non-A, non-B hepatitis' reflected the general acceptance by 1989 of the potential seriousness of NANB Hepatitis/HCV infection.<sup>314</sup> The topic is discussed in Chapter 15, *Knowledge of Viral Hepatitis 2 – 1975 to 1985* and Chapter 16, *Knowledge of Viral Hepatitis 3 – 1986 Onwards*.

**35.239** The feasibility of look-back for Scotland as a whole was accepted by mid-1994, and the potential seriousness of the infection had been acknowledged before the beginning of that decade. The logistics of the look-back exercise were burdensome, partly because of problems with record-keeping and the limitations in the computer systems then available, both of which contributed to the difficulty in tracing patients – not an easy task in itself as a result of name changes and changes of address. But those difficulties had to be resolved in 1995, and the resolution of them is unlikely to have become less difficult with the passage of time. The effectiveness of the treatment, or treatments, available for HCV continued to be discussed by expert committees until almost the end of 1994.

<sup>313</sup> Dr Keel – Day 86, pages 107–108

<sup>314</sup> Chapter 16, *Knowledge of Viral Hepatitis 3 – 1986 Onwards*, paragraphs 16.37–16.39

**35.240** In 1993 and 1994 Interferon therapy was controversial. It is not clear that very many individuals, in fact, lost a chance of treatment. It was widely held that the prospects of effective treatment with Interferon, certainly alone, were poor. Furthermore, treatment was unpleasant and poorly tolerated by patients. However, as any treatment options developed, in terms of the range of product and their effectiveness, information of HCV status would have been of interest to patients and might have affected their receptivity to treatment, notwithstanding the risk of side-effects. For patients who were informed of their exposure to HCV, such information might have encouraged them to abstain from alcohol entirely, or reduce their consumption of it, and adopt a different lifestyle despite the absence of effective treatment for their condition.

**35.241** So far as the direct responsibility of Scottish Ministers is concerned, Lord Fraser of Carmyllie responded with reasonable speed to the advice tendered by Dr Keel and her legal colleagues. That was advice generated in Scotland, and underscored the responsibility of Scottish Ministers for health policy north of the border. However, in the final analysis, the availability of safe and effective treatment was always going to be a crucial factor. The SACTTI report presented to the ACVSB/MSBT on 10 November 1994 did not resolve matters to the satisfaction of that expert committee. Only when Interferon was licensed in November 1994 was the way clear. In all the circumstances prevailing, it cannot be said that look-back should have been introduced generally in Scotland before November 1994.

**35.242** As concluded in Chapter 3, *Statistics*, the investigations made by the Inquiry suggest that further epidemiological study will not produce a more reliable estimate of the number of people in Scotland who have been infected with HCV as a result of transfusion with blood or blood components. The number infected can only be estimated, and the Inquiry's best estimate can be found in Table 3.21 of that chapter. Whatever the number, every one of those still alive is likely to benefit from identification, testing and treatment. Some may have already so benefitted, but others will not have done so. Accordingly, the more pressing practical problem is how to identify all of those so infected in order to ensure that all may be offered effective medical care.

**35.243** The SNBTS look-back exercise, described in this chapter, ran until 1998 using data available following the introduction of anti-HCV screening in September 1991. That look-back exercise had necessary limitations. First, any HCV positive donors who had donated before screening began would not be screened unless they returned to donate after September 1991. Secondly, the look-back study lacked the highly efficient patient tracking systems available today. Early donor card records were not searchable and different transfusion centres and hospitals had different record keeping systems. Difficulties were encountered in cross referencing donation numbers and recipients and vice a versa. Medical records had been lost or destroyed. Some recipients had changed their names through marriage or other causes. Some recipients had changed addresses.

**35.244** Due to the inevitable limitations of the look-back exercise as described above, there will still be recipients of HCV positive blood who remained, or remain, unaware of that fact. Some of those will have cleared the virus naturally. Some will have died either as a result of age, the life-threatening condition that resulted in transfusion being required, HCV itself or from other causes. However, a number of the recipients will not have cleared the virus, will be alive and at risk of the disease progressing and of infecting others. Some of those who are symptomatic among that group may have sought medical attention,

have had their condition diagnosed and be receiving treatment for it. However, a number will remain who are either asymptomatic or whose condition has not yet been diagnosed despite their symptoms, particularly if they received a transfusion in the years leading up to the introduction of screening. Dr Mutimer, Consultant Hepatologist, suggested that the median time from infection to cirrhosis in younger patients was about 30 years.

**35.246** Significant symptoms are likely to manifest themselves as the condition progresses. Treatment is available which might arrest the development of the disease, and it tends to be more effective if given prior to the onset of cirrhosis and related complications. Attempts have been made to alert individuals thought to be at risk of HCV through a number of government initiatives including the *Hepatitis C Action Plan for Scotland*.<sup>315</sup> That plan has been much praised and was described by the World Hepatitis Alliance recently as 'a model of best practice'.<sup>316</sup> On 25 August 2011 the Scottish Government brought together sexual health, HIV, Hepatitis C and Hepatitis B into the *Sexual Health and Blood Borne Virus Framework 2011–2015*.<sup>317</sup> The framework built on the success of the *Hepatitis C Action Plan for Scotland: Phase II*<sup>318</sup> and *Respect and Responsibility*<sup>319</sup> as well as further developing the *HIV Action Plan in Scotland*.<sup>320</sup> However, as the majority of Scottish patients suffering from HCV have tended, historically, to become infected through drug use, the bulk of the practical measures outlined in the *Action Plan* and in the *Framework* are aimed at that cohort. Unfortunately, a stigma is attached to the condition in consequence of its drug related and substance abuse association, and the framework acknowledges that raising awareness of Hepatitis C among health professionals is also a significant challenge.

**35.247** Patients with bleeding disorders, registered with UKHCDO on the National Haemophilia Database, are also affected by the transmission of HCV. They are a well-defined group of individuals. Those who test HCV positive are being managed by, and receiving treatment from, haemophilia clinicians and other specialists as required. Their condition is subject to routine monitoring including by liver function tests.

**35.248** The transfusion patients have only one common characteristic namely that they received an infected transfusion at some date prior to September 1991 in the course of medical or surgical treatment. As previously indicated, not all recipients of HCV positive blood were traced by the look-back exercise. There are therefore individuals who may well remain unaware of their HCV positive status. Any measures designed to reach those suffering drug use-related HCV are less likely to reach, or identify, these individuals. These people are, however, likely to benefit from testing and, if appropriate, modern anti-viral treatment.

## **Recommendation**

The Inquiry recommends:

That the Scottish Government takes all reasonable steps to offer an HCV test to everyone in Scotland who had a blood transfusion before September 1991 and who has not been tested for HCV.

# APPENDIX 1

## INQUIRY PROCEDURES

### Terms of Reference

The Terms of Reference for the Inquiry were agreed between the Scottish Ministers and Lord Penrose. By letter to Lord Penrose dated 12 January 2009 the then Cabinet Secretary for Health and Wellbeing, Nicola Sturgeon MSP, provided further explanation of certain aspects of the Terms of Reference. An amendment to the Terms of Reference for the Inquiry was announced on 13 November 2009 to include three additional deaths which were to be investigated and a further amendment to them was made on 22 February 2011 to remove one of those individuals from the investigation. The Terms of Reference as amended are:

#### Term of Reference 1:

To investigate the systems in place in Scotland for the collection, treatment, licensing, testing, preparation for supply and supply for use by the NHS of blood and blood products with particular reference to the risks of transmission of the Hepatitis C virus and HIV to patients treated by the NHS in Scotland, including the role of government in regulation and setting guidelines and standards.

#### Term of Reference 2:

To investigate the systems in place for informing patients treated by the NHS in Scotland of the risks associated with the use in their treatment of blood or blood products, with particular reference to the risks of infection with the Hepatitis C virus and HIV.

#### Term of Reference 3:

To investigate the systems in place in Scotland for obtaining consent from, and testing for infection with Hepatitis C and HIV, patients treated with blood or blood products, and informing any patients found to be so infected.

#### Term of Reference 4:

To investigate the systems for recording and monitoring the numbers of NHS patients in Scotland treated with blood and blood products, with particular reference to the numbers exposed to risk of infection with the Hepatitis C virus and HIV and the numbers contracting either or both such infections as a consequence of such treatment.

#### Term of Reference 5:

To examine the circumstances generally in which patients treated by the NHS in Scotland became infected with Hepatitis C, HIV, or both through the use of blood or blood products in the course of their treatment, taking account of the development of scientific and clinical understanding and evidence internationally.

#### Term of Reference 6:

To investigate the deaths of Reverend David Black, Mrs Eileen O'Hara, Alexander Black Laing and Victor Tamburrini, with particular reference to the circumstances in which they became infected with the Hepatitis C virus, HIV or both.

#### Term of Reference 7:

To investigate the steps taken by those involved in, and those responsible for, the NHS in Scotland, including NHS Boards and the Scottish National Blood Transfusion Service

(SNBTS), their officers and employees and associated agencies, once Hepatitis C and HIV were identified, to trace individuals who might have become infected with one or both of them as a result of receiving blood or blood products; and to identify any other or further steps that might reasonably have been taken to trace such individuals.

Term of Reference 8:

To investigate the steps taken by those involved in, and those responsible for, the NHS in Scotland including NHS Boards and the SNBTS, their officers and employees and associated agencies, to prevent the provision of infected blood and blood products.

Term of Reference 9:

To investigate the steps taken by those involved in, and those responsible for, the NHS in Scotland including NHS Boards and the SNBTS, their officers, employees and associated agencies to inform individuals who might have received infected blood or blood products of the risks associated with their treatment for themselves and their families; and to offer treatment to any individual at risk, and to identify any other or further steps that might reasonably have been taken to inform and to treat such individuals.

Term of Reference 10:

To examine any particular adverse consequences for patients treated by the NHS in Scotland, and their families, of infection through blood and blood products with Hepatitis C and HIV, including the treatment offered.

Term of Reference 11:

To identify any lessons and implications for the future, and make recommendations.

Term of Reference 12:

To report as soon as practicable.

### **The Inquiries Act 2005 and the Inquiries (Scotland) Rules 2007**

The Inquiry was established under the Inquiries Act 2005 ('the 2005 Act'). Inquiry procedures were governed by the 2005 Act and the Inquiries (Scotland) Rules 2007 ('the 2007 Rules').

### **Procedure Directions, Guidance Notes and Restriction Orders**

Section 17 of the 2005 Act states that, subject to the provisions of the Act itself or of the 2007 Rules, the Chairman of the Inquiry may make his own directions as to the procedure and conduct of the Inquiry. Under this section, Lord Penrose issued a number of procedure directions and guidance notes which were published on the Inquiry's website. These are listed in Appendix 5.

Sections 19 and 20 of the 2005 Act provide that restriction may be imposed on attendance at an Inquiry or any particular part of it and on disclosure or publication of any evidence or documents given, produced or provided to an inquiry. Under these sections of the 2005 Act the Chairman made the restriction orders listed in Appendix 5.

### **Preliminary hearing and the two phases of the Inquiry**

On 31 March 2009 a preliminary hearing was held at which the Chairman outlined the approach he intended to take to the conduct of the Inquiry and in fulfilling his remit.

The Inquiry was conducted in two broad phases.

The purpose of phase 1 was to focus the issues which the Inquiry required to consider at the public hearings and, having regard to the Chairman's obligations under section 17(3) of the 2005 Act (duty to act with fairness and to avoid any unnecessary cost), to reduce the length of these hearings.

Phase 1 of the Inquiry consisted of:

- The gathering of documentary evidence from various sources.
- The taking of witness statements.
- The consideration of the evidence with the aim of establishing as much as possible of the medical and scientific background and identifying the controversial facts and issues which required further investigation.
- The drafting and publishing of the Preliminary Report.

Due to the volume of documentation which the Inquiry examined, the complexity of the medical and scientific background and the extent of the time period covered by the Inquiry's Terms of Reference, a decision was made early in the Inquiry process that it was both appropriate and necessary for the Inquiry to produce a Preliminary Report. The aim of the Preliminary Report was to provide the results of the Inquiry's research and analysis of the information received and the evidential background to the topics identified in the Terms of Reference in order to provide a basis on which to move forward and examine the areas of controversy at the public hearings.

Phase 2 of the Inquiry involved:

- The gathering of further evidence.
- Holding public hearings into the issues which had been identified as requiring further investigation (see 'List of topics ...' section below).
- Sending warning letters and considering the responses to these.
- Writing the Final Report containing a detailed analysis of the evidence on the topics and the conclusions reached in respect of these.

### **Call for evidence**

On 24 June 2009 the Inquiry issued a public call for documents and witness statements relating to the Inquiry's Terms of Reference. This call for evidence was made in a press release to the national, local, online and broadcast media (including all health correspondents). All persons and organisations holding documents relevant to the Terms of Reference were invited to contact the Inquiry Secretary to discuss the documents held and the best means of producing them. In addition, patients who contracted Hepatitis C and/or HIV through receiving blood and/or blood products from the NHS in Scotland, and the relatives of such patients, who wished to provide a statement were asked to contact the Inquiry.

The Inquiry also sought to reach potential witnesses with a call for evidence on its own website, in a Google advert, by Twitter and on Facebook. The Inquiry distributed a poster and leaflet to all haemophilia centres in Scotland and to all health boards asking that they be distributed to all GP practices. With the help of Community Pharmacy Scotland the posters and leaflets were also sent to all pharmacies in Scotland. Haemophilia Scotland distributed the leaflets through its membership newsletter and promoted the Inquiry through its website and through membership meetings.

On 18 March 2010 Lord Penrose made a radio broadcast on Radio Scotland to appeal for more witnesses to come forward. At this time a further call for witnesses was made in local newspapers across Scotland.

### **Notices for, and request for, production of evidence**

Section 21(2) of the 2005 Act gives the Chairman the power to require a person to provide evidence to the Inquiry in the form of a written statement and to provide any documents in his or her custody or under his or her control that relate to a matter in question at the inquiry.

As this is a Scottish inquiry, section 28(4) of the 2005 Act provides that those powers are not exercisable so as to require any evidence document or other thing to be given, produced or provided by or on behalf of, amongst others, Her Majesty's Government in the United Kingdom.

The use of these statutory powers to recover documents did not necessarily mean that an organisation was unwilling to assist the Inquiry. Where an organisation held documents containing personal data or which were confidential, then providing the documents to the Inquiry in response to a Section 21 Notice meant that the data were lawfully processed.

On 17 September 2009 Lord Penrose served a notice under section 21 of the 2005 Act on Scottish Ministers requiring production of all documents in their custody or under their control relating to the Inquiry's Terms of Reference and dating from the period from 1 January 1974 to 31 December 2006. In response to that notice, the Scottish Government produced over 37,000 documents to the Inquiry. At the request of the Inquiry, two officials from the Scottish Government provided written witness statements in relation to the procedures for the identification and production of those documents and to explain the position as regards documents that had been destroyed or were being withheld by reason of legal professional privilege.

On 2 October 2009 Lord Penrose served a notice under section 21 of the 2005 Act on the Common Services Agency for the Scottish Health Service requiring the production of 482 Scottish National Blood Transfusion Service files listed in the Appendix to the Notice. The 482 files in question were selected by the Inquiry Team from an index, referred to as 'the documentation account', which had been prepared by the SNBTS in anticipation of requests for production of documents from its records. In view of the importance of the documentation account in the identification of the files to be produced to the Inquiry, a request was made to the SNBTS for a witness statement on various issues arising in relation to its preparation. Such a statement was provided by the SNBTS Public Inquiry Team Co-ordinator.

In 2006 the Department of Health commissioned a review of all documents held between 1970 and 1985 in relation to blood safety. The *Review of documentation relating to the safety of blood products 1970-1985 (Non A non B hepatitis)* was issued on 22 May 2007. Early in 2009 the Inquiry advised the Department of Health that it would require files relating to blood and blood products between 1986 and 1991. In September 2009 the Department of Health produced a list of about 166 files they had identified as possibly relevant to the Inquiry. Many such files ran to several volumes. On 26 October 2009 the Inquiry requested copies of documents previously disclosed by the Department of Health in terms of Freedom of Information releases. After further correspondence with

the Department of Health in June 2010 the Inquiry advised the Department of Health that it was particularly interested in files between 1 January 1989 and 1 September 1991 relating to the testing of donated blood for Hepatitis C. The Inquiry indicated 50 files which appeared to it to be of relevance and these files, together with some others, were made available for inspection by the Inquiry. Between 1 and 4 November 2010 two members of the Inquiry Team visited the Department of Health to review files of potential relevance to the Inquiry. As a result of this visit the Inquiry was provided with 63 documents.

### **Documentary evidence**

Nearly 120,000 documents were recovered from both public and private sources. The majority came from the records of the Scottish Government and various NHS bodies.

In addition, statements were provided by patients and their relatives, clinicians and others. These statements were often accompanied by supporting documents.

Appendix 2 gives further information about how the documentary evidence was processed and used by the Inquiry.

### **Annual summaries and framework document**

Much of the Inquiry's work during the first year consisted of the team considering the documentary material as it was recovered. This task was undertaken by means of summarising the relevant documents and then inserting references to the documents in summaries prepared for each of the key years – the annual summaries. Within each annual summary, documents were referred to under three separate headings: developments in respect of HIV; developments in respect of HCV; and developments in respect of blood products. From these annual summaries the main events relevant to the Terms of Reference were extracted. The Inquiry drafted a framework document containing the references of all documents relevant to the Terms of Reference. This framework document ran to 107 pages and became a timeline reference for subsequent work of the Inquiry.

### **Taking of statements from patients and relative witnesses**

The Inquiry engaged three statement takers to meet with and take statements from the patient and relative witnesses. These statement takers were provided with specific training for this purpose.

Those witnesses who attended the Inquiry for the purpose of giving their witness statements were entitled to apply for an award of travel and subsistence expenses and/or for compensation for loss of time, under Procedure Direction No. 2.2 – Award of Travel and Subsistence Expenses 1 April 2011 (original direction dated 22 June 2009) and Procedure Direction No. 4.1 – Award of Compensation for Loss of Time 17 February 2011 (original direction dated 22 June 2009).

Seventy-eight patient and relative statements were finalised prior to the publication of the Preliminary Report. These 78 statements were reported on in Chapter 4 of the Preliminary Report. A further 81 patient and relative statements were finalised after the Preliminary Report was published. This figure excludes the witness statements taken from the relatives of those whose deaths were specifically referred to the Inquiry under Term of Reference 6. The witness statements are summarised in Chapter 4. The identities of these witnesses were not disclosed to any other party.

## Core Participants

Rule 4 of the 2007 Rules provides that the Chairman may designate a person as a Core Participant in the Inquiry. A 'Core Participant' is usually understood to refer to a participant who will be expected to have a key role during the inquiry, attending for all or substantial parts of the proceedings, either personally or by their recognised legal representatives, and participating actively in the proceedings by making statements or asking questions, subject to the control of the Chairman.

In deciding whether to designate a person as a Core Participant, the Chairman must have particular regard to the desirability of including persons who fall within certain categories stated in Rule 4(2). These categories include those who have a significant interest in an important aspect of the matters to which the Inquiry relates.

It was impracticable and inconsistent with the Chairman's duties under section 17(3) of the 2005 Act (duty to act with fairness and to avoid any unnecessary cost) to designate as a Core Participant every person who had a significant interest in the Inquiry. Given the number of people infected with Hepatitis C or HIV and their family members, such an approach could have resulted in a substantial number of people being designated as Core Participants. Instead, the Chairman considered that a process of selection was required to ensure that the main groups of those with an interest in the subject matter of the Inquiry were represented as Core Participants.

A public invitation was extended to those interested to apply, by 7 July 2010, for designation as a Core Participant. Over 70 applications were received from patients and relatives of patients. Applications were also received from the personal representatives of the five deceased named in Term of Reference 6, the Scottish Ministers, the Common Services Agency for the Scottish Health Service on behalf of the SNBTS, the 14 Scottish Area Health Boards and the Haemophilia Society (known in Scotland as 'Haemophilia Scotland').

All the patients and relatives who applied for designation as Core Participants were represented by Thompsons, Solicitors. On 16 July 2010 the Chairman gave further guidance to these applicants on how he proposed to select those to be designated as Core Participants. He stated that he proposed to designate Core Participants (a) to reflect the distinct interests that could be identified from the circumstances set out in the applications and any relevant witness statements, and (b) to ensure that no more Core Participants were designated than were sufficient to ensure that Thompsons was adequately instructed to represent those interests at the hearings. A hearing was held on 10 August 2010 to consider submissions on this proposed approach.

Following the hearing, the Chairman decided that patient and relative Core Participants should be selected under appropriate groupings of interests, namely:

- Transfusion cases up to and including 1979.
- Transfusion cases in the 1980s.
- Transfusion cases in the 1990s.
- Hepatitis C cases associated with Haemophilia A up to and including 1979.
- Hepatitis C cases associated with Haemophilia A in the 1980s.
- Hepatitis C cases associated with Haemophilia B up to and including 1979.

- Hepatitis C cases associated with Haemophilia B in the 1980s.
- HIV cases associated with Haemophilia A or B.

Fourteen patients and relatives who fell within these groupings were provisionally designated as Core Participants, subject to these persons consenting to being so designated. An issue arose as to whether it was necessary for the identities of those who were designated Core Participants to be published. Having considered representations made on behalf of the provisional Core Participants the Chairman decided that only the initials of the Core Participants and the class of interest under which they had been selected would be published. He also decided, to ensure fairness to all concerned, that their identities would only be disclosed to the other Core Participants, subject to explicit undertakings of confidentiality. On that basis, on 30 September 2010, all 14 provisionally designated Core Participants consented to their designation. One further Core Participant was designated in December 2010 to illustrate two of the groupings listed above.

Those designated as Core Participants and their recognised legal representatives are listed in Appendix 3.

### **Funding of Core Participants**

All the individual Core Participants were awarded the expenses of their legal representation. Section 40 of the 2005 Act provides that the Chairman may award reasonable amounts in respect of legal representation in relation to the Inquiry. This section provides that such awards may be made to those attending the Inquiry to give evidence or to produce documents and to persons, including Core Participants, whether individuals or representative bodies, considered by Lord Penrose to have a sufficient interest to justify an award. Rules 17 to 20 of the 2007 Rules make detailed provision in relation to awards. Rule 18 provides that the Chairman has to take into account the financial resources of the applicant and the public interest so far as relating to the making of an award. In addition, a Determination by Scottish Ministers made under section 40(4) of the Act stated certain qualifications and conditions on the Chairman's power to make such awards. The Chairman issued an Inquiry Procedure Direction No 3.1, Applications for legal representation at public expense, in which he provided details about the procedure and conditions for applying for and being awarded such expenses.

### **Publication of Preliminary Report**

On 8 September 2010 the Inquiry published its Preliminary Report. The Preliminary Report set out the evidential background to the topics identified in the Terms of Reference. It did not reach any conclusions on matters of fact. It identified matters that appeared to be controversial and which required further investigation.

### **List of topics for investigation at the public hearings**

The Preliminary Report contained a draft list of topics which the Chairman considered should be examined at the public hearings in light of the Inquiry investigations to date. Responses to this list, including proposed additions or modifications to it, were invited from anyone who had suggestions to make. Fifteen submissions were received and considered. In February 2011 the draft list of topics was finalised taking account of these submissions. The list of topics investigated at the public hearings was as follows:

## **Part A**

The deaths of Reverend David Black, Mrs Eileen O'Hara, Alexander Black Laing and Victor Tamburrini, with particular reference to the circumstances in which they became infected with the Hepatitis C virus, HIV or both.

## **Part B – HIV/AIDS**

B1) The efforts made to discourage 'higher risk' donors from giving blood (by the dissemination of information, including leaflets); whether these efforts went far enough and began early enough.

B2) The use of blood product concentrates in Scotland, including any perceived disadvantages of such products, from their introduction in or around 1974; the continuation of the use of commercial concentrates in particular after:

- International realisation that these carried a risk of AIDS.
- The proposal by Dr Galbraith of the Public Health Laboratory Service in May 1983 that use in the UK should be stopped.
- Significant progress towards self-sufficiency in the manufacture of blood products by the NHS in Scotland had been made.

B3) The implementation of heat treatment against LAV/HTLV-III by the Protein Fractionation Centre in Scotland in December 1984, and the technological background to such implementation, including the history and exploration of methods of heat inactivation by the Scottish National Blood Transfusion Service.

B4) The decision not to use kits from the United States of America for testing donated blood for the virus as soon as they became available but, instead, to follow a process of evaluation of the kits before any such use.

B5a) The information given to patients (or their parents) about the risk of AIDS before their treatment with blood or blood products.

B5b) The tracing and testing of patients who might have been exposed to the virus through their treatment with blood or blood products.

B5c) The information given to patients who might have been infected, or who were found to be infected, and their families.

B5d) In particular, the circumstances in which those patients known collectively as the Edinburgh Cohort became infected with HIV, the testing of such patients for HIV and the information given to them about their infection.

B6) The effects of infection with HIV, including the effects of treatment, on patients and their families.

## **Part C – Hepatitis C**

C1) The acceptance of blood from 'higher risk' donors, in particular:

C1a) Prisoners.

C1b) Donors who had a history of jaundice, and who were negative for Hepatitis B when the existence of Non-A Non-B Hepatitis was known and its presence could not be excluded.

C2) The non-introduction in Scotland of surrogate testing for Non-A Non-B Hepatitis.

C3) The implementation of heat treatment sufficient to inactivate Hepatitis C in blood products by the Protein Fractionation Centre in Scotland in 1987, and the technological background to such implementation, including the achievement of this objective by the National Blood Transfusion Service in England and Wales in 1985.

C3a) The use of blood product concentrates in Scotland in the period between the introduction of NHS heat-treated products in 1984 and the supply of NHS products sufficiently treated to inactivate Hepatitis C.

C4) The interval between the availability of tests for the Hepatitis C virus in 1989 and the introduction of screening of donated blood for the virus in the United Kingdom in September 1991.

C5a) The information given to patients (or their parents) about the risk of non-A, non-B Hepatitis and the severity of the condition before their treatment with blood or blood products.

C5b) The tracing and testing of patients who might have been exposed to the virus through their treatment with blood or blood products.

C5c) The information given to patients who might have been infected, or who were found to be infected, and their families.

C6) The effects of infection with Hepatitis C, including the effects of treatment, on patients and their families.

Topic C3A was added to the list of topics in August 2011, in response to representations from Core Participants.

### **Preparation of topics for public hearings**

Each topic was assigned to one of the Inquiry Counsel and a paralegal. They were responsible for the preparation of each topic for the public hearings and leading the evidence on it.

Inquiry Counsel prepared notes on the line of evidence for most topics detailing the matters which required further investigation at the public hearings, the evidence required for this – namely, the witnesses and the documentary evidence – and any further investigations to be undertaken.

The paralegals sent requests for statements to witnesses. These requests asked the witnesses to provide a written statement of their evidence to the Inquiry and stated the specific matters about which the Inquiry wished the witnesses to provide information. Such requests often included documentary evidence which the Inquiry considered would assist the witnesses in this task and which the witness could consider before providing his or her statement.

Once such statements were finalised the witnesses were asked to provide a signed statement. These statements were then shared with the Core Participants on a confidential basis in advance of the public hearings. Usually they were published on the Inquiry's website.

A few witnesses were either unable or unwilling to provide a statement.

## **Procedure at the public hearings**

The Inquiry produced a document *Guidance on the Oral Hearings* which set out guidance on what the Inquiry expected from Core Participants and their legal representatives and from witnesses giving oral evidence to the Inquiry and on what could be expected from the Inquiry Team.

The Inquiry heard evidence and submissions on 89 days between 8 March 2011 and 30 March 2012. Hearings were generally held from Tuesday to Friday with a morning and a lunch break each day. They were arranged in blocks with the Inquiry endeavouring to hear all evidence on individual topics together within a block.

A further procedural hearing was held on 29 October 2012 to allow Lord Penrose to hear submissions on behalf of the patients, relatives and the Haemophilia Society that certain witnesses be called to give further evidence on the topic of Statistics.

In terms of Inquiry Procedure Direction No. 6 the Chairman directed that no opening statements be made by Inquiry Counsel or by, or on behalf of, the Core Participants.

All witnesses who were required to attend the hearings were sent a notice by the Chairman under section 21(1) of the 2005 Act. 67 witnesses gave evidence at the hearings. These witnesses are detailed in Appendix 4. Each witness took the oath or made an affirmation before giving their evidence.

The Inquiry endeavoured to release to the Core Participants a list of all witnesses required to attend to give evidence related to a topic four weeks before the commencement of the respective hearings.

The Inquiry endeavoured to produce to the legal representatives of Core Participants and, where considered necessary, to witnesses the documents relied on in each topic four weeks before the start of the evidence in respect of that topic. There was a database – Courtbook – of such documents for the use of the legal representatives of the Core Participants. Appendix 2 provides further information about Courtbook. Within Courtbook documents were grouped and inventoried according to each topic. Witnesses who wished to refer to a document during their evidence were asked to produce such a document to the Inquiry no later than two weeks prior to the start of the evidence on that topic.

Questioning of witnesses was primarily carried out by Inquiry Counsel. Counsel for the Core Participants questioned witnesses on areas of importance. Initially, they were required to have obtained the Chairman's approval to do so but more flexible arrangements were introduced as the hearings progressed.

During the hearings special applications were made by the Core Participants and on behalf of witnesses to allow further documents, including additional statements and comments, to be received in evidence. In addition at times supplementary written information was requested from some witnesses.

## **Evidence of patient and relative witnesses**

Thirteen individuals were selected from all the patient and relative witnesses to give oral evidence at the public hearings for Topics B6 and C6 (the effects of infection with HIV and Hepatitis C) as being representative of, or at least as illustrating, some of the main themes that emerged from the initial statement gathering exercise. The Inquiry selected

those it considered would paint as clear and as wide a picture as possible of the severe side-effects of infection with either HIV or Hepatitis C, including the effects of treatment, on themselves and their families. Factors which were taken account of in selecting these witnesses included:

- The means by which a person was infected with the virus(es).
- The severity of the effects of infection and the effects of treatment.
- The nature and range of the effects of infections and the effects of treatment.
- Where a patient or relative lived and where he or she received treatment.
- The sex of the patient or relative.
- The age of the patient or relative.
- The occupation of the patient or relative.
- Whether the patient suffered from a pre-existing or other medical condition which meant that it was difficult to distinguish the effects of the infection with the virus.

After identifying potential witnesses to give evidence, the Inquiry wrote to these witnesses asking them if they would be prepared to do so. At the time they were asked to give evidence each of these witnesses was sent a copy of the Inquiry's *Guidance on the Oral Hearings*. In addition to being provided with information about giving evidence anonymously (see section on anonymity below), each witness was offered the opportunity to give evidence by video conferencing or from behind a screen. None of the witnesses chose to do so.

Those asked to give evidence were also advised that, as a person attending the Inquiry to give evidence, they might be entitled to legal representation and advice at Inquiry expense. Some of these witnesses chose to be legally represented and they were represented by Thompsons, Solicitors.

The Inquiry recovered all the medical records of those witnesses who agreed to give evidence. These medical records were then considered with the witness's statement before a final decision was made about that witness giving evidence.

### **Anonymity and protection of identity of patient and relative witnesses**

It was decided that all patient and relative witnesses giving evidence at the hearings would not have their names or identities disclosed, even if they had no objection to this. This meant that the evidence of these witnesses could be heard on an equal basis.

In order to preserve anonymity, the Inquiry redacted copies of the statements and medical records of these witnesses. All details from which the witness could be identified were redacted from these documents. Each witness had the final say on the information which was redacted.

The redacted witness statements and medical records were made available only to the legal representatives of Core Participants and were provided only after they had given confidentiality undertakings.

Restriction Orders were made restricting those who could attend the hearings at which these witnesses gave evidence to members of the Inquiry Team, Counsel and one representative of the solicitors representing the designated Core Participants and any person authorised by the Chairman to accompany the witness during the hearing of that witness's evidence. The Restriction Orders also prevented the disclosure or publication of their oral evidence or documents revealing their names and identities.

Each witness chose a pseudonym under which they gave evidence and by which they are referred to in the Final Report.

### **Evidence of relatives of Mr Tamburrini and Mrs O'Hara**

Two family members gave oral evidence at the hearings during the investigations into the specific deaths. These were Mrs Jean Tamburrini and Mrs Roseleen Kennedy. Both witnesses were identified and their unredacted witness statements were made available to Core Participants and put on the Inquiry's website.

### **Final written submissions and final hearing**

Core Participants were directed to submit their final written submissions to the Inquiry and to intimate them to the legal representatives of other Core Participants by 5pm on 26 March 2012. Inquiry Counsel did not prepare submissions but set out a list of 67 questions which they suggested fell to be answered.

The final hearing took place on 30 March 2012. The hearing was divided into two parts. During the first part of the hearing, Counsel appearing for the Core Participants each made a brief statement explaining the approach adopted in relation to their written submissions and highlighting any points considered to be of particular importance. During the second part of the hearing Counsel for the Core Participants made closing statements in terms of Rule 10 of the 2007 Rules.

### **Warning letters procedure**

Rule 12(7) of the 2007 Rules provides that the Inquiry must not include any significant or explicit criticism of a person in the report unless the Chairman has sent that person a warning letter and given that person a reasonable opportunity to respond to it. Neither the 2005 Act nor the 2007 Rules define what is meant by a 'significant or explicit criticism' and so the Inquiry gave these words their common sense meanings.

In terms of Rule 12(2) a warning letter must –

- (a) state what the criticism or proposed criticism is;
- (b) contain a statement of any facts that the Chairman considers may substantiate the criticism or proposed criticism;
- (c) refer to any evidence or documents which may support those facts;
- (d) invite the person to make a written statement if the person wishes; and
- (e) note that the information is subject to confidentiality restrictions.

Rule 12(3) provides that the Chairman may send copies of any evidence or documents referred to with the warning letters if he considers it appropriate to do so.

The Inquiry sent 103 warning letters under Rule 12(7) of the 2007 Rules. The Inquiry sent warning letters to those persons criticised in the final report and to those persons who were subject to criticism by another person when that criticism was narrated in the Report.

Recipients of these letters were allowed 28 days and in a few cases, on cause shown, a longer period to respond. The Inquiry received 100 responses to warning letters. The responses included supporting documentation and together these totalled over 1000 pages.

All responses were carefully considered and, if it was deemed appropriate and/or necessary, the Report was amended to take account of information provided in them.

### **Keeper of the Records of Scotland**

At an early stage of the Inquiry the Chairman consulted the Keeper of the Records of Scotland on the manner and format of creating, maintaining and transferring the records of the Inquiry to the National Records of Scotland (NRS).

In terms of Rule 16(3) of the 2007 Rules at the end of the Inquiry the Chairman will transfer the records of the Inquiry to the NRS.

## APPENDIX 2

### INQUIRY ORGANISATION AND ADMINISTRATION

#### The Inquiry Team

As Chairman of the Inquiry, Lord Penrose was independent of government or any other body or organisation. He alone was appointed to investigate the matters raised by the Terms of Reference.

Oliver James, Emeritus Professor of Medicine at the University of Newcastle, was appointed to act as the medical assessor to the Inquiry under section 11 of the 2005 Act. He was the principal adviser to the Inquiry on medical matters. He had 30 years' experience as a Consultant Physician and was a former Senior Vice President of the Royal College of Physicians (London).

Senior Counsel to the Inquiry was Laura Dunlop QC who was assisted by Euan Mackenzie, Nick Gardiner and Jane Patrick, Advocates. They did not represent any organisation or person appearing before the Inquiry. Their role was strictly impartial, assisting Lord Penrose to investigate the facts, examining witnesses at the hearings, providing advice on questions of law, evidence and procedure, liaising with Counsel for the Core Participants and assisting with the drafting of the Inquiry reports and other documents produced by the Inquiry.

Gillian Gibson (Galbraith), Advocate, assisted the Inquiry with the warning letters process and with the drafting of the Final Report.

The Solicitor to the Inquiry was Douglas Tullis assisted until June 2014 by Louyse McConnell-Trevillion, the Deputy Solicitor. They were responsible for the provision of legal advice, liaising with solicitors for the Core Participants, dealing with claims for expenses and drafting procedural documentation. Heike Gading and then Andrea Summers took on the role of Solicitor to the Inquiry after Douglas Tullis retired in December 2013.

The Secretary to the Inquiry was Maria McCann, assisted by Diane Barr and then Sarah Noble as Deputy Secretary. The Secretary was responsible for all administrative arrangements for example: commissioning an Inquiry office and hearings venue, the organisation of IT support, recruitment and management of paralegal and administrative staff, handling the Inquiry's finances, drawing up and implementing the Inquiry's communication strategy, including maintenance of the Inquiry's website. The Secretary and her team were also responsible for managing the publication of the Preliminary and Final Reports. The Documents and Evidence Manager was Neil MacFarlane assisted by Oliver Stempt and Keith Fleming. Neil and Keith also contributed to the drafting of the Final Report. At different times, members of the administrative team included: Fraser Paterson, Meg Orr, Kate Miguda, Sheila Renton, Rhona Carr, Samantha Doherty, Philip Brough, Lorna Gibson, Claire Stapley, Edin Omanovich, Kimberley Meikle, Kristina Hanson, Fiona McLean and Helen Fleming.

The Inquiry employed a number of paralegals, many of whom were, in fact, qualified lawyers. They developed expertise in particular subject areas of the Inquiry and used this expertise during different stages of the Inquiry, including to code documents and to assist Inquiry Counsel in preparing for and during the public hearings. Those who assisted the Inquiry as paralegals at various stages of the Inquiry were Angus Evans, Jenny Livingstone, Gemma

Lovell, Stuart McWilliams, Gregor Mair, Janet Marsh, Jennifer Murphy, Teri Pidgeon, Lindsey Robertson, Charles Rogers, Yasmin Shepherd, Lorna Young and Laura Weir.

Sascha Cochran, Margaret Fraser and Jane Patrick were the statement takers responsible for taking the statements from patients and relatives. Margaret Fraser was appointed Witness Liaison Manager for the public hearings.

Mary Jane Bennett provided editing and proofreading services for the Preliminary Report and the Final Report. Murray Earle and Stefania Greci provided proofreading services for the Final Report.

### **Accommodation**

The Inquiry leased office accommodation within the Scottish Legal Aid Board ('SLAB') premises at 44 Drumsheugh Gardens in Edinburgh. Due to the relocation of SLAB, on 29 September 2014 the Inquiry moved to Victoria Quay, Edinburgh.

The preliminary hearing on 31 March 2009 took place at Edinburgh International Conference Centre, The Exchange, Edinburgh. The public hearings were held at accommodation specifically leased for that purpose at Clydesdale Bank Plaza, 50 Lothian Road, Edinburgh. The procedural hearings on 10 October 2010 and on 29 October 2012 were held at the Apex International Hotel, 31-35 Grassmarket, Edinburgh.

### **Inquiry IT**

The Inquiry's basic administrative IT systems were supplied by the Scottish Government as part of their SCOTSLite service, a service made available to smaller Scottish public bodies.

The Inquiry was very conscious from the outset that it could expect to receive a large quantity of documentary evidence. It was clear that IT systems would be required that were specifically designed for the handling and presentation of large numbers of documents.

Mike Taylor of i-Lit Ltd, an expert on IT for litigation and inquiries, provided advice on the selection of IT systems.

Tenders were invited through an Office of Government Commerce (OGC) framework agreement: Specialist Solutions – Electronic Document and Records Management Solutions. Framework Agreement Code A217837/L11.

The successful contractor was Computacenter (UK) Ltd. Working through a number of partners, Computacenter provided the Inquiry with a range of document processing services including initial processing, a document management system, and hearing room display systems.

### **Inquiry's website and bulletins**

The Inquiry's website was launched on 10 February 2009. It was set up and maintained by Whitespace. It contained background information, key documents relating to the Inquiry, a witness timetable showing which witnesses were scheduled to give their evidence on a particular day, transcripts of the evidence heard at the public hearings, frequently asked questions and the preliminary report. It was updated regularly during the course of the Inquiry. This report is available on the Inquiry's website.

The Inquiry issued four bulletins during the course of the Inquiry to provide the public with a progress report and an insight into the work of the Inquiry Team.

## **Document storage**

The Inquiry made use of Systematics Signature Delium database ('Signature database'). Over 118,000 documents were entered into this database. In addition to the material obtained from the Scottish Ministers, the SNBTS, the Department of Health and Lothian Health Board, over 1600 documents were collected in the course of the Inquiry including witness statements, documents provided by witnesses, medical records, scientific papers and journal articles. Assistance in configuring and managing the database was provided through the Computacenter contract by Elizabeth Miller and Alexander Parkes.

The initial processing of documents was carried out by Hobs Legal Docs in London. Services covered the scanning of paper files, the preparation of images and searchable versions of documents, and the inputting of various basic pieces of descriptive information for each document. In the event, most of the documents recovered by the Inquiry had already been scanned by the organisations providing them. This meant that there was little need to transport files to London for scanning, and Hobs were able to concentrate on the preparation of image files and descriptive data for loading into the Signature database.

It was clear to the Inquiry that the bulk of document recovery would occur in the early stages of the Inquiry and that there would need to be a system in place that could quickly assess documents for evidential significance. It was decided that there would be an initial coding exercise for these documents.

Once documents had been loaded into the Signature database the Inquiry Team undertook a subjective coding exercise to identify the issues that a document addressed and to assess the relative importance of the document.

Documents thought to be of interest were put through a second review undertaken by members of the Inquiry Team who had developed more detailed knowledge of the key issues during particular time periods. This review considered the importance level assigned to documents. Those documents which were still considered to be important after the second review were linked into the database's Chronology Manager which allowed a timeline to be developed. These documents were then passed to Inquiry Counsel.

It is important to note that documents not considered directly relevant at this stage remained in the Signature database and would still appear in search results. This ensured that documents whose significance might not have been obvious at an early stage of investigations would be available during more detailed investigation of particular topics.

As noted above, the subjective coding process was designed to deal with the initial receipt of large numbers of documents at the one time. Once these bulk deliveries had been completed, it was no longer considered necessary to formally have documents subjectively coded, as the smaller numbers of documents being received meant that they could be assessed for relevance directly. They were still looked at by Inquiry Counsel.

The main Signature database was only available to members of the Inquiry Team.

## **Public hearings: sharing documents**

In preparation for the public hearings the Inquiry Team set up a separate version of the Signature database which would be available to the legal representatives of the Core Participants and which would also support the display of documents in the hearing room. Courtbook, as it was known, was initially set up with all the documents published

with the Inquiry's Preliminary Report. Documents and witness statements for each of the topics to be examined during the public hearings were exported from the Signature database and imported to Courtbook so that the Core Participants' legal representatives could use them to prepare for hearings. Core Participants' legal representatives were also able to ask for documents to be added to Courtbook.

Documents were checked before copying them to Courtbook so that sensitive personal data could be redacted.

By the end of the Inquiry nearly 5000 documents had been placed into Courtbook.

The Inquiry Team provided training to Core Participants' legal representatives on the use of Courtbook and helped them to configure their IT systems to allow access to the database.

### **Hearing room systems**

The specification for the hearing room systems was drawn up by Elizabeth Miller and the work of building and installing the systems was subcontracted by Computacenter to the NVT Group.

The server for the Courtbook database was installed in the hearing room premises throughout the period of public hearings. This was done to reduce the number of possible points of failure between the server and the hearing room when documents were being displayed.

Courtbook included tools for publishing documents as they were used in the hearings, and these tools were used to display Courtbook documents to Counsel, witnesses and the general public in the hearing room. The database allowed the Inquiry Team to record which documents had actually been exhibited and the witnesses with whom the documents had been used. At the end of each day's hearings any documents shown for the first time were exported from Courtbook and uploaded to the Inquiry's public website so that in due course they could be linked to the published transcript of the day's proceedings.

During the hearings, Counsel would read out the reference of any documents that they wished to show to a witness. The hearing room operator would call up the document on his PC and then publish it to monitors in front of the Chairman, the witness and the legal teams. Two large plasma screens were installed at the front of the public seating area so that members of the public could see the documents as they were being put to witnesses.

The hearing room network provided wired and Wi-Fi internet connections for the Inquiry Team and for Core Participants' legal representatives. Wi-Fi was also available for the press and the general public.

### **Hearing transcripts**

A live transcription service was provided throughout the hearings by Merrill Legal Solutions. The stenographer was Catherine Anderson and the Editor was Stuart Marshall.

The Chairman and the legal teams were able to access the live transcript as it was created, allowing them to refer back quickly to earlier passages of evidence. The legal representatives could highlight or annotate sections of evidence for future reference. At the end of each day a corrected and checked version of the transcript was provided to the Inquiry Team, who then uploaded it to the Inquiry's website. The following day active links

were added to the transcript on the website so that readers could open up any documents that were referred to during the hearing.

The transcripts of the evidence of those patient and relative witnesses who gave evidence anonymously were redacted prior to being uploaded onto the Inquiry's website. Each patient and relative approved the redactions made.

### **Video conferencing**

Video conferencing facilities were set up in the hearing room to allow the Inquiry to take evidence from witnesses who would otherwise have found it difficult to take part. It also made it possible for a witness who was appearing in connection with more than one topic to give his or her evidence in separate video conferences to fit in with the logical order of the evidence rather than appearing in person for a whole day to deal with a range of topics.

### **Data protection**

The Inquiry was registered under the Data Protection Act 1998.

### **Public relations**

Media and public relations support was provided to the Inquiry by Golley Slater under a Scottish Government Marketing Services Framework agreement.

### **Report**

This report is published on behalf of the Inquiry by APS Group Scotland Ltd under the Scottish Government contract for supply of design, print, publishing and associated services.

## APPENDIX 3 CORE PARTICIPANTS

The following individuals and organisations were designated by the Inquiry Chairman under Rule 4 of the Inquiries (Scotland) Rules 2007, which provides that:

(1) The chairman may designate a person as a core participant at any time during the course of the inquiry (but only with the consent of that person).

(2) In deciding whether to designate a person as a core participant the chairman must have particular regard for the desirability of including as core participants persons who-

....

(b) have a significant interest in an important aspect of the matters to which the inquiry relates....

Legal representatives of Core Participants are noted at the top of each table.

<b>Personal representative of those whose deaths were investigated under Term of Reference 6</b>	<b>Legal Representative: Thompsons Solicitors</b>
Mrs Jeanie Black as personal representative of the Reverend David Black	
Mrs Roseleen Kennedy as personal representative of Mrs Eileen O'Hara	
Mrs Annie Laing as personal representative of Alexander Black Laing	
Mrs Jean Tamburrini as personal representative of Victor Tamburrini	
<b>Anonymised Core Participants, designated by Chairman to illustrate different grouping of interests</b>	<b>Legal Representative: Thompsons Solicitors</b>
Transfusion cases up to and including 1979 – JF	
Transfusion cases in the 1980s – EF; KM	
Transfusion cases in the 1990s – No designation [Mrs Annie Laing, as representative of Alexander Black Laing, deceased, is already designated and covers that interest]	
Hepatitis C cases associated with Haemophilia A up to and including 1979 – FM; PD	
Hepatitis C cases associated with Haemophilia A in the 1980s – MM; BW; JM2	
Hepatitis C cases associated with Haemophilia B up to and including 1979 – DB; IB; JD	
Hepatitis C cases associated with Haemophilia B in the 1980s – RM	
HIV cases associated with Haemophilia A or B – JM; GM; KM2; JM2	
<b>Patient interest organisations designated as core participants under rule 4 (2) (b)</b>	<b>Legal Representative: Thompsons Solicitors</b>
The Haemophilia Society	
Haemophilia Scotland (designated February 2014)	

The Common Services Agency, the 14 area Health Boards and Scottish Ministers were designated under the other provisions of rule 4 (2) of the Inquiries (Scotland) Rules 2007.

<b>Designated as Core Participants under provisions of rule 4 (2)</b>	<b>Legal Representative: Directorate for Legal Services (Solicitor to the Scottish Government)</b>
The Scottish Ministers	
<b>Designated as Core Participants under provisions of rule 4 (2)</b>	<b>Legal Representative: Central Legal Office (CLO)</b>
The Common Services Agency for the Scottish Health Service (on behalf of the Scottish National Blood Transfusion Service)	
Ayrshire and Arran Health Board	
Borders Health Board	
Dumfries & Galloway Health Board	
Fife Health Board	
Forth Valley Health Board	
Grampian Health Board	
Greater Glasgow Health Board	
Highland Health Board	
Lanarkshire Health Board	
Lothian Health Board	
Orkney Health Board	
Shetland Health Board	
Tayside Health Board	
Western Islands Health Board
